TROZEN, a town of the Peloponnesus, in the interior of Messenia. Ptol. tomenty.

TREZENE, a town of Asia Minor, in Caria. Strabo.

TROGILUS, a country of Macedonia. Steph. Byz.

TROGLODYTE, TROGLODYTE, formed of τρυγλυτς, caverna, and ους, I enter, a people of Ethiopia, said to have lived in caves under ground.

Pomp. Mela gives a strange account of the Trogloidytes.
—He says, they did not so properly speak as Hriek; and that they lived on serpents, &c. Tzetzes calls them Ἰθήβιοσια. Montanus takes them to be the same with those called in Scripture Ghananim. Pintianus in Strabo will have the name written without the I, Trogolitis.

These Trogloidytes, so called by the Greeks from their principal habitations in natural caverns, or in mountains excavated by their own labour, were probably, as Sir William Jones conjectures (Works, vol. iii. p. 166, 8vo.) the first inhabitants of Africa, where they became in time the builders of magnificent cities, the founders of seminaries for the advancement of science and philosophy, and the inventors (if they were not rather the importers) of symbolical characters. Upon the whole he concludes, that the Ethiopians and Meroë were the same people with the Phrygian Egyptians, and hence likewise, as might be easily shewn, with the original Hindos. We have already, aided by the conjectures and historical details of the learned Bryant, and of the indefatigable traveller Bruce, traced the probable origin of these people under the article Cushi. Having accompanied the Cushiotes or Cushites in their migrations to Abyssinia, and conjectured the reason of their forming excavations in the mountains and rocks for their habitations, we shall now attend them in their peregrinations towards the south. Besides other arts, with which they seem to have been acquainted, they employed themselves in astronomical observations; and accordingly wished to defend themselves from the tropical rains and cloudy skies, that hindered their correspondent observations with their countrymen, defended from the fame ancestors, who had established themselves at Meroë and Thebes. But upon advancing within the southern tropic, they still found rains; and, therefore, constructed hovels, such as the fear of a deluge had induced them to prepare. They found solid and high mountains in a fine climate; but, more fortunate than their countrymen to the northward, they found gold and silver in large quantities, which determined their occupation, and constituted the riches and confecution of their country. In these mountains, called the "mountains of Sofala," large quantities of both metals were discovered in their pure and unmixed state, lying in globules without alloy, or any necessity of preparation or preparation. The balance of trade, to long against the Arabian and African continents, turned now in their favour, from the immense influx of these precious metals, found in the mountains of Sofala, just on the verge of the southern tropical rains. The northern colonies advanced gradually from Meroë to Thebes, intent upon the improvement of architecture and building of towns, which they began to substitute for the caves which they and their ancestors, the Cushiotes, originally occupied; and they thus became traders, farmers, artificers in various branches, and even practical astronomers, from having a meridian night and day free from clouds, for such was that of the Thebaid. As their brethren, who still inhabited the mountains, did not enjoy similar advantages, being confined by fixed months' continued rain to their caves, we naturally imagine that their foedantic life would render them useful in reducing to practical purposes the observations daily made by those of their countrymen who lived under a purer sky. Letters too, or at least one fort of them, and arithmetical characters, as we are informed, were invented by this middle portion of the Cushites; while trade and astronomy, the natural history of the skies and feaons, were employing that part of the colony which was established at Sofala, more to the southward. The very nature of the commerce of the Cushites, the collecting of gold, the gathering and preparing of ipices, necessarily fixed them perpetually at home; but his profit depended on the diffipation of these ipices through the continent, otherwise his mines, and the trade produced by the possession of them, would be of little avail. A carrier was necessary for the diffipation of their disposable commodities; and such they found in their own vicinity. These carriers were denounced Berers or Shepherds, as well as distinguished by other appellations of similar import. These shepherds of the Thebaid and Ethiopia were wholly employed in the dispersion of the Arabian and African goods all over the continent; and they rove to be a great people. As that trade increased, their cattle multiplied, and consequently they increased in number, and the extent of their territory was enlarged. Nothing was more opposite than the manners and life of the Cushites, and his carrier the shepherd. The first, although he had forsaken his caves, and now lived in cities which he had built, was neccesarily confined at home by his commerce, amassing gold, arranging the invoices of his ipices, hunting in the feaon to provide himself with ivory and with food through the winter. The mountains, and the cities he afterwards built, were situated upon a lowly, black earth, so that as soon as the tropical rains began to fall, he was deprived of his cattle, by fraughts of flies (see Zins) which appeared wherever that loamy earth was; which made him
absolutely dependent upon the shepherd, who was himself also affected by this circumstance. The shepherd, as a carrier, was enabled to perform his long and toilsome journeys across Africa by means of the camel, emphatically called by the Arabs "the ship of the desert." When Carthage was built, the caravans of this commerce fell into the hands of the Libyans, and became a great accession to the trade, power, and number of the shepherds. For a further account of these shepherds, see Shepherds of Egypt.

As the Abyfthinians of the Arabian flock had no symbols of their own to represent articulate sounds, they borrowed those of the Troglydotes above mentioned; and to them we may with probability trace the origin of the Abyfthinian written language, or the Ethiopic, which is a dialect of old Chaldean, and a filter of Arabic and Hebrew; and many improvements in science and the arts, as well as in commerce, at an early period, were introduced into Africa, and through Abyssinia and Ethiopia into Egypt, by these people. It has indeed been suggested that the Gypsies (see the article) were Troglydotes from the rocks near Thébes, where a race of banditti still resemble them in their habits and features; but it seems more probable that the Gypsies, whom the Italians call Zingaros and Zinganos, were not other than Zinganians, who might, in some piratical expedition, have landed on the coast of Arabia or Africa, where they might have rambled to Egypt, and at length have migrated, or been driven into Europe.

TROGLODYTES is also an appellation given to a sect of Jewish idolaters.

The prophet Ezekiel relates, chap. viii. ver. 8, 9, 10, &c. that God, among other abominations of the Israelites, which he set before him, shewed him twenty old men, who, with their censers in their hands, adored secretly all kinds of animals and reptiles painted on the wall.

Philaffrion, on this vifion of the prophet, erects these idolaters into a sect of Israelites, who, hiding themselves under ground, and in caves, adored all kinds of idols.

And yet the prophet plainly shews, that it was in secret parts of their houles, and not in subterraneous caverns, that these seventy Israelites idolatrized. The name Troglydotes, then, is feigned; and so, probably, is the sect.

TROGLODYES, in Ornithology. See Wren.

TROGODOS, TROGODUS, or TROBUS, in Geography, a name given by the Greeks of the present day to mount Olympus, which divides the island of Cyprus longitudinally. In order to distinguish it from another mountain of the same name in Natalia, and from another more famous in Macedonia, the ancients gave this the name of "Little Olympus." On its summit they had built a temple dedicated to Venus, the entrance of which, by a regulation very strange for a spot consecrated to the goddess of Love, was prohibited to women: they were even forbidden to look at it. To this temple, an elegant and sacred recess, where were celebrated the enjoyments of nature, had succeeded treaties erected for privations. Numbers of convents were built on the same ground. There, laborious Canebites embellished the slope of the mountain with gardens, and plantations of all sorts, laid out with taste. This was the most charming abode in the island; and the rich Cypriots went thither, during the summer, to enjoy the coolness of agreeable groves, watered by limpid streams, directed with considerate art. Insensible to a happy harmony of nature and industry, the Turk has carried his ferocity and ravages into this beautiful district: the monasteries have been demolished, and cool and cheerful spots have been clothed with the rugged garb of sterility. Sonnini.

TROGON, CURUCU, in Ornithology, a genus of the Picæ; the characters of which are, that the bill is shorter than the head, cultivated, hooked, and ferrated at the margin of the mandibles; the nostrils are covered with bristles; and the feet, short, simple, covered with down, are formed for climbing, having two toes forward, and two backward.

The birds of this genus are mostly inhabitants of South America; they feed on fruits, and all agree in their general habits of life. In Guiana they are denominated Curucous or Curucu, from their notes being very much like that word.

Species.

STRIGLIATUS. Cinereous, with a fulvous abdomen; wings frigiate with white; tail-feathers black, the three lateral ones outwardly banded and tipped with white. The cinereous curucu of Latham. Inhabits Cayenne and Guiana.

CURUCU. Golden-green; of a fulvous red beneath; throat black; wing-coverts and the three exterior tail-feathers white, tipped with black. Red-bellied curucu of Latham. Of this species there are several varieties, viz. one mentioned by Maregrave, which had the wing-coverts plain brown, the bill aht-coloured, irides fafnron-coloured, and without the bare spot under the eye mentioned by Brifon in his description,—another, with a yellow abdomen; the green yellow-bellied cuckow of Edwards,—another, described and figured by Buffon, of a cinerous grey, with very light traces of green-gold, especially on the back and middle tail-feathers; the lower part of the belly and the vent only being red; the tail very long, having the outer webs of the three lateral feathers and the tips white; the three outer quills are also marked with black and white on the exterior webs. This species is a very solitary bird, being found only in the thickest forests; and in pairing time never more than two are found together, when the male has a very melancholy note, never uttered except whilst the female is fitting. They pair in April, and lay three or four white eggs. The male, during the incubation of the female, supplies her with food, and by his fong helps to pass away the time. The young, when first hatched, are altogether without feathers, and are fed by the old birds with small worms, caterpillars, and insects; but are deserted by them, when they are able to fift for themselves; and the parent-birds return to their solitary haunts, till August or September, when they are prompted to produce another brood. At St. Domingo and in other islands these birds are called "Dame Angiloe," where attempts have been made to tame them, but ineffectually, as they refuse to eat, and consequently die. They are also found in Cayenne, Peru, Brasil, and Mexico.

VIRIDES. Golden-green; beneath yellow; throat black; with the three lateral feathers on both sides obliquely denated with white. The yellow-bellied curucu of Latham. Of this species there is a variety, viz. the left, with white abdomen: the white-bellied curucu of Latham. This species inhabits Cayenne.

RUFUS. Rufous, with the body beneath yellow; wings frigiate with black and grey; the three lateral tail-feathers frigiate with black and white, with white tips. The rufous curucu of Latham. Found in Cayenne.

VIOLEACEUS. Violet-coloured, with a green back; wing-coverts and secondary quills spotted with white; the three lateral tail-feathers barred with black and white, with white tips.
tips. The violet-headed curucui of Latham. Found in Cayenne.

MACULATUS. Striped with dusky and brown; crown green; wing-coverts and secondary quill-feathers green, white at the tips; tail dusky, with white bars. Spotted curucui of Latham; inhabiting Ceylon.

FASCINATUS. With a ferruginous back; body beneath fulvous red; head and neck dusky, with a white fascia on the breast; wings falcated with black and white; apex of the tail black. Faeicated curucui of Latham; inhabiting Ceylon, but rare, and called by the inhabitants "Rautvak-kondea."

ASIATICUS. Green, with the forehead, crown, and hind part of the neck red; throat blue, with a red spot; quills and tail-feathers black. Blue-cheeked curucui of Latham; inhabiting India.

YSIDICUS. Dusky, with ferruginous spots above; beneath yellowish, striped with dusky; head black, with white stripes; tail very long, and barred. Indian curucui of Latham; called in India by the natives "Bungummi."

NARINA. Above green, with a red belly. Male, with the head, neck, back, throat, jugulum, breast, and wing-coverts green, which last are greyish behind; quills black, bordered externally with white. Female, with the throat, jugulum, and wing-coverts brown; abdomen in front cinereant. Le Vaillant says, that this bird is an inhabitant of Caffaria, and the country of Autenicua to the river Gantoo, and that the name Narina, in the Hottentot language, signifies a flower. The female lays four nearly round eggs, and during her incubation the male has a melancholy note, but at all other times he is silent.

TROGUS POMPEIUS, in Biography, a Latin historian, flourished in the time of Augustus, and wrote 44 books, under the title of "Philippies," so called from their subjeft, which was the Macedonian empire, originating with Philip, the father of Alexander. An epitome of this work by Justin is extant. Justin denominates Trogus a man of ancient eloquence, and Pliny, who often refers to him in his Natural History, distinguishes him by the appellation of "severissimus auctor," as a most exact author.

TROJA, or TROJAN Games, Ludi Troiani, were games instituted by Aescanius, son of Æneas; and which afterwards passed to the Romans, and were celebrated in the Circus by the youth of Rome.

One of the number, who preceeded over the folemnity, was called princeps juvenitis; and was always of one of the first families in Rome. At first, it was fuppofed, they only engaged on foot, and on horfebæck; because Virgil, who describes these games in the Æneid, lib. v. only speaks of horfes and cavaliers, without any mention of biga or quadriga, which were not in use in Rome till long after Aescanius. And yet Dion, speaking of Caesar's games, says, the youth there combated in chariots: but it is thought by fome, that these were not the Trojan games, but races and combats of a different kind, proper for young people, of a more advanced age. The Trojan games were renewed by Augustus, after the victory at Actium, A.U. 726; began to decline under Tiberius, and terminated under Claudius.

TROJA, in Ancient Geography, a town of Chaula, in Cælia. Steph. Byz.—Alfo, a town or rather village of Egypt, in the vicinity of mount Troicus. This was the ancient habitation of the Trojans, who followed Menelaus to his captivity. Strabo.—Alfo, a town of Italy, at the bottom of the Adriatic gulf, in the country of the Veneti. Steph. Byz.—Alfo, a town of Asia, in Cilicia.—Alfo, a place of Italy, in the territory of the town of Larentum. According to Livy, it gave name to the place where Æneas landed, on his arrival in Italy; situated, according to Dion. Halic., four ftabia from the sea.

TROJA, or Troy, a celebrated city of Asia Minor, and capital of the small country called Troas, or Troade (which fee), and Phrygia Minor, situated to the north-west. See PHRYGIA Minor.

TROJA, in Geography, a city of Naples, in Capitanata, on the river Chilare, the fee of a bishop, containing six churches and six convents. It was built on an eminence, out of the ruins of Æneas, a city destroyed by Conflans II. It is said to have been founded by Baganus, catapar or viceroys of the province in the eleventh century, by order of the emperors Baflil and Conflantine, as a bulwark against the intruders of the Norman adventurers, and to have had its name in commemoration of the famous city, which, by its fall, immortalized the heroes of Greece. It was long accouunted a key to the Apennines, and as such was exposed to many afaults and sieges; 33 miles S.W. of Manfredonia. N. lat. 4° 24'. E. long. 15° 18'.

TROJA, a small island in the Mediterranean, near the coast of Italy. N. lat. 42° 43'. E. long. 11° 5'.

TROJAN, a town of Servia; 16 miles S. of Sabaca.

TROIL, among Tullies, denotes a thief, or occasion of merriment, by eating and drinking; called also a duggle.

TROILNSKÁIA, in Geography, a town of Ruflia, in the country of the Coftack, on the Don; 80 miles E. of Azoph.

TROIS-CINQUE, in the French Distillery, a term used to express their brandy, when of a peculiar strength, consisting of five parts alcohol and three parts phlegm.

The method of distilling the wines into brandy in France, is exactly the fame with that used with us to draw the spirit from our wafh or fermented liquor of malt, treacle, fugar, or whatever other kind. They only observe more particularly to throw a little of the natural lee into the fill along with the wine; and the poorest wines are fure to succeed best on the trial, making by much the finest brandies. We are apt to wonder that we cannot, from the wines of particular countries, distil their particular brandies; but the whole mystery confits in this, that they do not fend us over the fame wines which they use in distilling, because thefe latter would not be liked as wines, nor would keep in the bringing over. Sometimes in Scotland they meet with the poor and pricked wines, the fame that the French distil their brandies from; and from thefe they ditil a spirit, not to be known from the brandy distilled in France.

The lee which the French add in the dilillation gives the brandy that high flavour for which we so much esteem it; but they themselves like it fo much the worfe for it. The French notion of a proof strength, determined by the chaplet or crown of bubbles, is the fame with ours; and all their fine fpirits are found of this strenght.

But they have one particular expedient for thofe brandies which prove foul and feedy, or retain the taste of certain weeds which grow among the wines; they draw them over again, with a defign to free them from that adventitious flavour. In this operation they always leave out the fants, or rather they change the receiver as soon as ever the freem comes proof; then mixing together all that ran off before, they make a brandy ftronger than the ordinary kind, and this is what they call trois-cinque.

The distillers in France feareely ever bring their brandies higher than this; for they have the art to perufade the foreign merchant, that the phlegm of French brandy is

natural
natural and essential to it: but the truth is, that the spirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and sent over in the flate of alcohol, and then lowered with common water to the proper strength.

The French use no art in colouring their triois-cinque, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour; the thing which they principally value themselves upon, both in regard to brandies and wines, being to make them perfectly natural: so that all the colour we find in their brandies, is acquired from the colour, and the time they are left in it. This is often twelve or eighteen months, sometimes two or three years; in this time they acquire a brown colour, and lose their acid taste.

The greatest adulteration of brandies is in England: the French have no temptation to do it, they having no cheaper spirit, since the prohibition of molasses in their country. The Dutch are in the same condition, having no molasses-spirit, and only a very coarse and nauseous fugar-spirit, and a yet worse malt-spirit of their own manufacture; a single gallon of which would spoil a whole piece of brandy. The French brandy also paying no duty in Holland, is as cheap, or nearly so there as in France itself. The duties being high upon brandy in England, it is greatly adulterated, and that with all sorts of spirits; as malt, molasses, cider, and fugar-spirits; and when this is done in a dexterous and sparing manner, the cheat is not easily detected. Shaw's Elflay on Dillbury.

TROIS MARIES, Les, in Geography, a town of France, in the department of the Mouths of the Rhone, by the inhabitants of the country held a sacred place, as having been, according to tradition, the residence of the three Maries, and Lazarus after our Saviour's crucifixion; 15 miles S. of Arles.

TROIS RIVIERES, Les, a town of Canada, on the river St. Lawrence, lying nearly midway between Quebec and Montreal, and so called from three rivers, into which the river St. Maurice is divided by two islands, whose streams unite about a quarter of a mile below the town, and afterwards fall into the great river of St. Lawrence. It was formerly the capital of the French government in New France, and much referred to by several nations which come down those rivers to it, and trade in various sorts of furs. The town contains about 250 or 300 houses, and ranks as the third town, in respect of size, in the provinces. It is one of the oldest settlements in the country, and its founder, it is said, calculated upon its becoming in a short time a city of great extent. It has lighthouse, however, increased but very slowly in size, nor can it be expected to improve much, at least until the country bordering upon the river St. Maurice becomes settled. The bank of iron ore in its vicinity, which promised opulence, is nearly exhausted. The fur-trade also, from which great benefit was expected, is now almost wholly transferred to Quebec and Montreal; and it is merely the small quantity of furs brought down the St. Maurice, and some of the northern rivers that fall into the St. Lawrence, nearer to the town of Trois Rivières than to Quebec or Montreal, that is shipped there. These furs are laden on board the Montreal ships, which float opposite to the town as they go down the river. The streets of Trois Rivières are narrow, and the houses in general small and indifferent, many of them being built of wood. In the town are two churches, an English Episcopal, and a large Roman Catholic parish-church, formerly served by the Recollets, or Franciscan friars, but the order is now extinct in Trois Rivières. The old monastery of the order is defetred, and the houses near it lie uninhabited. The college or monastery of the Jefuits, a large old stone-building in the same neighbourhood, has been converted into a gaol. The only religious order at present existing in the town is that of St. Ursula, the filter-house of which is the convent can well allow. This was founded by M. de St. Vallier, bishop of Quebec, in the year 1677: the building is spacious, and situated near that formerly belonging to the Recollets; and annexed to it under the same roof is a hospital, attended by the nuns, and containing about twelve or fourteen beds, for the convenience of patients, who are well accommodated. The filter of this convent are particularly distinguished for their curious work made of the bark of the birch-tree, and of which they manufacture pocket-books, work-baskets, dressing-boxes, &c. which they embroider with elk-hair, dyed of the most brilliant colours. They also make models of the Indian canoes, and various warlike implements used by the Indians. Almost all the birch-bark canoes in use on the St. Lawrence and Utawa rivers, and on the nearer lakes, are manufactured in Trois Rivières, and its vicinity, by Indians. These canoes are constructed very neatly, and on the water they appear very beautiful. The canoes are so light, that two men can easily carry on their shoulders one that is capable of containing six people. Their size varies, some being sufficient for only one person, and others capable of accommodating any number as far as twenty. They are navigated with paddles, and move with surprising velocity. The country in the vicinity of Trois Rivières has been represented by some French travellers as wonderfully fertile, and as one of the most agreeable parts of Canada; but, according to Mr. Weld (Travels through Lower Canada, vol. ii.) it is totally the reverse. It is a level barren tract, and so sandy, that in walking along many of the streets of the town, and the roads in the neighbourhood, you sink into the land at every step above the ankles. The air, also swarms with midges, indicating the low damp situation of the place; 44 miles W.S.W. of Quebec. N. lat. 46° 23'; W. long. 72° 20'.

TROIS RIVIERES, a bay on the E. coast of the island of St. John, in the gulf of St. Lawrence.—Also, a river of St. Domingo, formed by the union of three streams, and running into the sea on the N. coast of the island, near Port Paix.

TROISSEREUX, a town of France, in the department of the Oise; 4 miles N.W. of Beauvais.

TROITZ, or TROITSKOE MANOFR, that is, The Convent of the Holy Trinity, a convent of Rullia, which is so large, as at a little distance to have the appearance of a small town; and, like many convents in this country, is strongly fortified, according to the ancient mode of defence, being surrounded with high brick walls, strengthened with battlements and towers. Befide the convent or habitation for the monks, the walls inclose an imperial palace, and nine churches, constructed by different sovereigns. The convent is a large range of building encircling a court, and is far too spacious for the present inhabitants. It formerly contained 300 monks, together with a proportionate number of students; and was the richest ecclesiastical foundation in Rullia. The fraternity possessed considerable estates, upon which were at least 100,000 peastats: these estates, as well as all the other church-lands, being now annexed to the crown, the members receive small pensions. With their revenues their number has been greatly diminished, and they scarcely amount
amount at present to 100 monks. Their habit is black, with a veil of the same colour; they eat no meat, and the discipline of the order is very strict. This convent is distinguished in the annals of this country as the asylum for the Russian sovereigns, in cases of inauguration or danger; and is more particularly known to foreigners for the refuge it afforded to Peter the Great, when he put an end to the administration of his father Sophia; 40 miles from Moscow.

TROITZK, a town of Russia, in the government of Penza; 76 miles W.N.W. of Penza. N. lat. 54° 43' 34". E. long. 43° 34'.

TROITZKOE, a town of Russia, in the government of Upha; 200 miles E. of Upha. N. lat. 54° 40'. E. long. 61° 44'. Alfo, a town of Russia, in the government of Upha; 16 miles N.E. of Sergievsk.

TROITZKOV, a town of Russia, in the government of Simbirsk; 20 miles N. of Sizran.—Alfo, a town of Russia, in the government of Archangel, on the Pineg; 38 miles S.E. of Pineg.—Alfo, a town of Russia, in the government of Upha; 40 miles N.W. of Belebcov.—Alfo, a town of Russia, in the government of Tobolok, on the Oby; 204 miles N. of Tobolok. N. lat. 61° 24'. E. long. 42° 50'.—Alfo, a town of Russia, in the government of Tobolok; 40 miles N.W. of Naram.—Alfo, a town of Russia, in the province of Ufug; 32 miles S. of Lalk.—Alfo, a town of Russia, in the government of Kolrom; 40 miles S. of Vetugala.—Alfo, a town of Russia, in the government of Kolrom; 12 miles N. of Vetugala.—Alfo, a town of Russia, in the government of Tobolok; 14 miles N.E. of Tafhevolko.

TROKI, or TROCKI, a town of Lithuania, and capital of a palatinate to which it gives name. This town was built by the great duke Gedimyn, in the year 1321, and is situated among lakes; it was formerly the residence of the great dukes, who afterwards removed their seat to Wilna. In the year 1655, it was demolished by the Russians; 16 miles W. of Wilna. N. lat. 54° 33'. E. long. 24° 44'.

TROLHETTA, a town, or rather village, of Sweden, in Welf Gothland; 15 miles E.S.E. of Uddevalla. For an account of the canal of Trolhettta, see Caskal.

TROLLING, among Anglers. To troll, is to fish for pikes with a rod whole line runs on a reel. See Pike-Fishing.

TROLLIUS, in Botany, a name given to this plant, our Globe-flower, by Conrad Geyner, which, though of barbarous etymology, has been universally retained. This might be attributed to respect for its illustrious author, were there not so many had reasons for which barbarous names have been admitted. The derivation of Trollus is said to be from an obsolete German word trol, or trölen, expressing any thing globular. Hence it is synonymous with the English name of this flower; as well as with the French one, boule d'or. Professor Martyn says, after Haller, "Trollilium, in German, seems to signify a magical flower." From what we have seen and heard of the feftive usages of the Globe-flower in the north of Europe, there appears to be some idea of this kind attached to it, which nevertheless may not be the origin of the name.---Linn. Gen. 282. Schreb. 378. Wild. Sp. Pl. v. 2. 1333. Mart. Mill. Dict. v. 4. Sin. Fl. Brit. 597. Ait. Hort. Kew. v. 3. 359. Pursh 391. Salif. Tr. of Linn. Soc. v. 8. 302. Juli. 233. Lanarcck Illistr. t. 499. Gartn. t. 119.---Clas and order, Polyandria Polygynia. Nat. Ord. Multi-flugas, Linn. Ranunculaceae, Jull.

Gen. Ch. Cal. none. Carp. Petals about fourteen, sometimes fewer, roundish-ovate, concave, converging, decussate, three in each outer row, five in the innermost. Nectaries about nine, linear, flat, incurred, perforated at the base within. Stam. Filaments numerous, linear, much shorter than the corolla; anthers linear, erect. Fil. Germens superior, numerous, stelle, columnar; styles short; stigmas pointed, shorter than the stamens. Peric. Capsules numerous, collected into a head, oblong, compressed, curved, pointed, bursting at the inner edge, of one cell. Seeds numerous, obovate, angular, polished, inserted along the inner edge of each valve.

Obf. Linnaeus erroneously in Gen. Pl. calls the capsules ovate and fingle-fed.

1. T. europaeus. European Globe-flower. Linn. Sp. Pl. 782. Willd. n. 1. Fl. Brit. n. 1. Eng. Bot. t. 28. Fl. Dan. t. 133. Lightf. Scot. 295. (Ranunculus globosus; Ger. Em. 955. R. fextus; Camer. Epit. 38. Globe Crowfoot; Petiv. Herb. Brit. t. 43. f. 2.)—Petals closely converging. Nectaries the length of the stamens. Native of mountainous, rather moist, meadows and pastures in the north of Europe, especially Lapland, Sweden, Germany, Switzerland, Wales, the northern counties of England, and Lowlands of Scotland, flowering in May and June. The root is perennial, of many flout fibres. Herb smooth. Stem erect, two feet high, round, leafy, branched in the upper part. Leaves deeply divided into many wedges-shaped, deeply cut and toothed, acute, spreading lobes; the radical ones on long stalks; the rest nearly feliaceous, alternate. Flowers solitary at the naked summits of the branches, erect, globar, above an inch wide, of an elegant bright uniform yellow. Nectaries obtuse. Seeds black. Haller and Lightfoot say the flowers are fragrant, which we have not observed. The Scotch call them Lucken-gowarts, or Cabbage-dailles. In Weltmoreland we have seen them flowers gathered by the peasants, with great feliavity, and made into garlands for the young men and women, as well as to decorate the porches of their cottages. Linnaeus mentions them as used in Sweden to strew the floors on holidays.

2. T. asiaticus. Asiatic Globe-flower. Linn. Sp. Pl. 782. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 235. (Hel-leborus aconiti folio, flore globo cresto; Amm. Ruth. n. 101.)—Petals spreading. Nectaries nearly equal to them in length. Native of the banks of rivers in Dauria. Amman.—A hardy, but not very common, perennial in our gardens, flowering in May or June. It requires a mixture of loam and bog earth, in a northern exposure, and must have due supplies of water in dry summers, for want of which we have, after several years successful cultivation, lost the plant. This species is very like the former in habit, though somewhat larger, with more copious and acute teeth, or ferratures, to the leaves. The flowers however are distinguished by their spreading petals, of a rich orange-colour, and the still deeper hue of their large and numerous nectaries, almost, or quite, equal to the petals in length. The flower being much more open than in T. europaeus, the nectaries, as well as stamens and pistils, are displayed in full view, and the whole makes a very handsome appearance.

TROLLEUS, in Gardening, comprises some hardy, herbaceous, flowery, perennial plants, as the globe ranunculus, or globe-flower, among which the species cultivated are the European globe-flower (T. europaeus); and the Asiatic globe-flower (T. aflaticus).

These two plants are of a rather tall hardy growth, affording considerable ornamental effect in their large flowers, which grow in the first fort in a particular converging manner, or turn in an inward direction, or somewhat revolute mode, so as to give them a perfect globular form, from which they derive the name of globe-flower. They appear in both forts in the beginning of summer. Those in the Asiatic or latter kind, however, are not convolutes, but spread out and shew some of the inner parts, which are of a fine saffron-colour, and display a striking elegant singularity in their appearance, which renders them highly valuable for their use in the flower-garden. They are both desirable flower-plants.

Method of Cultivation.—The means of propagation and increafe in these plants are occasionally by sowing the fresh seeds of them, and the parting of their roots.

In the former method, the seeds should be sown in shallow drills, in a somewhat flaky border or other place, in the autumn or spring, covering them in to the depth of nearly half an inch, when they readily grow and produce plants for setting out in other parts.

In the latter mode, the roots should be taken up in the autumnal season, when the leaves decay and fall off, or very early in the spring months, and be divided into several parts, but not by any means into too small slips, and then be planted out either where they are to remain, or in nursey rows, where they are to continue for twelve months, when they will be ready to set out finally.

The seedlings should be set out in summer, or towards the autumnal season, in rows about six inches asunder, where they are to continue about six or eight weeks, to become perfectly strong, and be finally planted out in places where they are to remain.

And the root-plants, which are set out in rows, may be removed in the autumn or spring seasons to the spots where they are finally to grow and continue.

As these plants are natives of moist and shady situations, they are generally the most successfully planted in places where the circumstances are the same in this climate, though they will commonly grow very well in any border or compartment of the garden which is not over dry, or without moisture.

These plants multiply extremely fast by the roots, and are of a great many years duration. They are highly deserving of a situation in all curious collections in the flower-gardens and pleasure-grounds, where they have a fine effect in the clumps, borders, and other compartments.

TROMBA, in Geography, a small island near the coast of Istria. N. lat. 45° 31'. E. long. 13° 52'.

TROMBA, in the Italian Music, either denotes the common trumpet, the buccina of the ancients, or the modern fophaeton, but more properly our trumpet.

TROMBETAS, in Geography, a river of Brazil, which runs into the river of the Amazons at Pauxis.

TROMBETTA, in Ichthyology, a name given by the Italians to the fifth commonly called sticpolax by authors. See Trumpet-Fish.

TROMBETTA, in the Italian Music, a small trumpet, being the diminutive of tromba.

TROMBONE, a wind-instrument blown by the mouth, and resembling in form the military trumpet, of which it is the base, the name implying the great trumpet. It differs, however, from the trumpet in being divided into two branches or parts fitted to sockets, giving the performer power to lengthen and shorten the general tube at his pleasure, according to the different tunes which he wishes to produce. On which account it is called in Latin, tuba ductilis. The Germans call it paufaune, and the French facuboute.

Zarlini has described this instrument under the title of trombone amovibile, and the quantity and quality of the founds it is capable of producing, very exactly.

"The trombone," says he, Supplimenti Musica, lib. iii. cap. 5. "is an instrument truly worthy of consideration, which I have seen and often heard by good performers, beginning at the lowest sound which it is capable of producing; when, being closed in all the joints, it can produce no found less than the octave; then from the octave to the 5th; nor from that can it produce a lews interval than the 4th; and from the 4th to the 5d major, then the 3d minor, after which another 4th, the key-note, from which it can form a complete series of eight notes. No other founds than these can be produced without altering, moving, and lengthening the instrument."

Père Merienne, in his experiments on this instrument, (Harmon. Infrac. lib. ii.) found it capable, by lengthening or shortening the lower part of the instrument, of forming a regular series of fifteen founds, from double C in the base, to C on the sixth line.

The instrument is made of brass, of which there are five forts: canto, alto, tenor, bafe, and double-bafe. It is much ufed in the large churches of Germany. They can produce all the tones and semitones in gradation. The manner of writing for them is the fame as for different voices, and on the fame staff of five lines.

Canto,
The double-bafe of this instrument goes a 5th lower than any other bafe. It has the finest effect in funeral processions, and in general in melancholy strains. We never hear it with more pleasure in England than in Handel’s dead march in Saul. Its use should be rare, and its effects would be more striking. But tromboni and double-drums are now so frequently used at the opera, oratories, and in symphonies, that they are now a nuisance to lovers of pure harmony and refined tones: for, in fact, the vibrations of these instruments produce noise, not musical sounds.

TROMELIA, in Ancient Geography, a town of the Peloponnesus, in Achaia Propria. TROMNES, in Geography, a small island in the North sea, near the coast of Lapland. N. lat. 68° 5'. E. long. 15° 26'.

TROMP, MARTIN HARPERTZOOON, in Biography, a famous Dutch admiral, was born at the Brill in 1597. At the age of eight years he was destined for the sea-service, and was sent on board a ship bound for the East Indies. Whilst he was very young he was taken prisoner by an English pirate, with which he continued for two years, acquainting himself with the stratagems and manoeuvres practised in that kind of service: and being afterwards employed in the Mediterranean, he was captured by the Turks, from whose custody he had the good fortune to make his escape. In the service of the States, he accompanied the famous Peter Hein in his various expeditions, and being his favourite, fought by his side when he was killed. By various gratifications he was advanced to the rank of admiral, and in February 1639, he pursuaded a Spanish squadron, and in an engagement off Graveline, captured and destroyed five men of war and four frigates. In October of the same year he engaged another Spanish fleet in the Downs, and obtained a glorious victory, taking or destroying the greatest part of the fleet, though sheltered by the English. On this occasion he saved the life of Oquendo, the Spanish commander, by sending a frigate to his relief, when his own ship was sinking. His name now became famous through Europe, and the king of France enrolled him by patent among the French nobility. In 1652, Tromp and Blake, the English admiral, had a rencontre in the Downs, in consequence of which the Dutch fleet, after having sustained some losses, was obliged to retire. Having on another occasion met with a disappointment in fulfilling his orders for attacking Blake by reason of a storm, he was disgraced and recalled, and De Ruyter was appointed to supercede him; but his command was restored to him in the same year. In November he attacked Blake, commanding an inferior force, in the Downs, and after a severe engagement, obliged him to retire into the Thames, with the loss of five ships. Tromp with some degree of arrogance triumphed, and fixed a broom on his top-mast, intimating vain-gloriously that he would sweep away the English from the Channel. This triumph, however, was of no long duration. In February 1653, the two powerful fleets of Holland and England had an engagement which lasted three days; one of which terminated in the loss of eleven men of war to the Dutch, but it is said that Tromp lost no reputation in this action. This engagement was succeeded by another off Nieuport, in which Tromp and De Ruyter mutually refused each other from imminent peril; but the termination of the contest was unfavourable to the Dutch, who suffered considerable losses. These two Dutch commanders made complaints to the States of the insufficiency of their equipment, and great exertions were made to supply them with both ships and men. In July, Tromp with eighty-five ships defeated the English fleet with ninety-four, but before they could come to an engagement, which was prevented by a storm, the Dutch fleet was augmented to 120 sail. On the 6th of August the opposing fleets rushed to action. The first day was indecisive: the second was unfavourable to Tromp, who, according to his usual practice, pierced the enemy’s line, and was surrounded, being defeated by his own squadron. Whilst he was fighting with desperate valour, he fell by a musket-shot, as he was giving orders on the deck, exclaiming, before he expired, “Take courage, my lads, I have run my course with glory!” The Dutch, having lost their commander, could not be re-animated, and a disaffraught, though dearly bought, defeat closed the day, and also the war. The remains of Tromp were interred with funeral honours in the church at Delft, and a magnificent mausoleum was erected to his memory. Un. Hist. Moreri.

TROMP, CORNELIUS, the second son of the preceding, was born at Rotterdam in 1629, and having been educated with a view to the navy, he was appointed, at the age of 19, to the command of a ship of war against the Corsairs on the Barbary coast. When the war broke out between England and the United Provinces in 1665, he was one of the admirals in the sea-fight off Solebay, when the Dutch fleet was defeated, though by his masterly retreat the victors were prevented from making the most of their success. In some subsequent engagements Tromp distinguished himself by his valour, though not always unbanded with temerity, and seldom with any great success. Complained of by De Ruyter, who was superior in command, he was superseded; but was he again employed till the year 1673, when the two rival admirals, being reconciled, fought
in concert and mutual assistance in the engagements with the French and English, off the Dutch coast, in June and August. After peace with England had taken place, Tromp, in 1675, visited London, and being honourably received, was made a baronet by Charles II. Having this year conducted a fleet to succour Denmark in its war with Sweden, he was invited by the king with the order of the Elephant. Upon the death of De Ruyter, in 1677, he was appointed his successor as lieutenant-admiral-general of the United Provinces. He continued, however, in the service of Denmark, and at the peace withdrew from the navy; but in 1691, when the war with France was renewed, he resumed his command. Whether a fleet was fitting out, he was seized by a disease which terminated his life at Amsterdam, on the 29th of May, in his 63d year. His remains were deposited in the magnificent tomb of his father at Delft. "Un. Hist. Moreri.

TROMPE, in the "Manges." See DESCEY.

TROMPERWICK, Gulf of, in Geography, a bay of the Baltic, on the north-east coast of the island of Ufedom; a dangerous road for vessels which are driven thither by the wind, or misguided by darkens. N. lat. 54° 40'. E. long. 13° 40'.

TROMSOE, an islet on the coast of Lapland, near the Storotnufis, or Great Rocky Cape; bare, in the Scandianvian dialect, signifying great, and hence probably are derived our words flære and flære-homu. Here, in the latitude of 69° 38', a village has been lately founded under the protection of the Danish government, and endowed with peculiar privileges and immunities; being intended to facilitate the exchange of commodities, and to diffuse the benefits of civilization over these fequeiterated regions. For two whole months at Tromsoe the sun never sets; and as he wheels his oblique apparent course, he skirts the northern horizon at midnight, and again attends with fiercer beams in progress of the day, the sky being, with little variation, bright and cloudless. The change of temperature is confined to a very narrow range. The greatest heat, on the 15th of July, was observed at 2 o'clock in the afternoon, when the thermometer rose to 61° or 62° Fahrenheit, and the greatest cold at 1 o'clock in the morning, when the thermometer stood at 50° or 52°. This low islet is covered with birches, though the prospect was fertilized by patches of snow lying still unmelted in the recesses, the gardens, and the fields. Von Buch's Travels in Norway and Lapland.

TRONAGE, TRONAGUM, an ancient custom, or toll, paid for the weighing of wool.

The word comes from trona, an old name for a beam used in weighing.

TRONATOR, an officer of the city of London, whose business it was to weigh the wool brought into that city.

TRONCHIN, Theodore, in Biography, a celebrated physician, was born at Geneva in 1700, and being disappointed in his expectations from lord Bolingbroke when he visited in England, he repaired to Leyden in order to study under Boerhaave, whose Elements of Chemistry he had perused; and after passing through a course of medical instruction, he graduated M.D. in 1730, publishing on the occasion a dissertation "De Nymphà," patronized by Boerhaave. He settled at Amsterdam, and became a member of the college of physicians and an inspector of hospitals. Here he distinguished himself as a zealous promoter of inoculation. In 1754 he returned to Geneva, and ranked among the most distinguished practitioners in Europe, not only on account of his established reputation, but from the number and quality of his patients. His native city erected in his honour a chair of medicine, and the Society of Palfron admitted him into their body. He was employed by the duke of Orleans in the inoculation of his children, and by other persons of rank at Paris; and in 1763 he went to Parma, for the purpose of inoculating the family of the duke. Although he declined to comply with the invitation of the empress of Russia to spend two years at Peterburgh, he accepted, in 1766, the offer of being principal physician to the duke of Orleans. His practice was simple, administering few medicines, and relying chiefly on diet and regimen, with the regulation of the passions and affections. In nervous complaints abounding in a luxurious capital, he recommended temperance and exercise. With the practice of inoculation, he patronized the cool treatment in the natural small-pox, and also the free admission of air in other diseases. On mothers he urged the fencing of their children. In the exercise of his profession he was exemplary for his humanity and charity. In conversation he was mild and modest, and in his manners agreeable and polite. He had little time for writing; but besides his inaugural dissertation already mentioned, he published a treatise "De Colica Pidonis," in 1757, and he contributed several articles to the "Encyclopædia," and to the "Memoirs of the Academy of Surgery." Of the works of Bailly, he gave an edition in 1762, with a preface on the state of medicine. He had the honour of being enrolled as a member of the chief medical and scientific societies in Europe. He died at Paris in 1781, in the 73d year of his age. Nouv. Dict. Hist. Gen. Biog.

TRONCO, in the Italian Mufes, by the French called coup de grace, is used to intimate to the voices as well as instruments, that they are not to draw out the found to its natural length, but cut it short; that is, only continue it long enough to be heard, by which means there is a small silence between each found; which has a very good effect in expressioms of grief, to make signs; and also in expressioms of wonder and surprize, &c.

TRONCONNE, or TRONCONNE, in Heraldry, denotes a crois or other thing, cut in pieces, and dismembered; yet so as that all the pieces keep up the form of a crois, though flat at a small distance from one another.

TRONE, in Agriculture, a term applied provincially to a drain or small trench of that kind, in some places.

TRON, in Geography, a town of Sweden, in Helsingland; 7 miles N.W. of Soderhamn.

TRONE Pound, in Scotland, contains twenty Scotch ounces. But because it is usual to allow one to the score, the trone pound is commonly twenty-one ounces.

TRONE Stone, in Scotland, according to sir John Skene, contains nineteen pounds and a half.

TRONE Weight was the fame with what we now call Troy weight.

TRONECKEN, in Geography, a town of France, in the department of the Sarre; 12 miles S.S.E. of Traarbach.

TRONINGE, a town of Sweden, in the province of Halland; 8 miles E. of Halmfled.

TRONIS, in Ancient Geography, a country of Greece, in the Phocides, which contained many ancient monuments.

TRONTO, a river which forms a boundary between the marquisate of Ancona and the province of Abruzzo Ultra, and runs into the Adriatic, N. lat. 42° 52'. E. long. 13° 59'.

TRONUM, in Ancient Geography, a place on the route from Dyrrachium to Salone, between Pons Tili and Bilidium. Anton Itin.

TRONZAN,
TRO

TRONZAN, in Geography, a town of France, in the department of the Po; 7 miles N.W. of Turin.

TROO, a town of France, in the department of the Loir and Cher; 10 miles S.W. of Vendôme.

TROON, a town of Scotland, and county of Ayr; N. of Troon Point.

TROON Bay, a bay on the W. coast of Scotland.

TROON Point, a cape on the W. coast of Scotland, and county of Ayr.

TROONGOOMBA, a town of Africa, in the kingdom of Ludamar; 12 miles S.W. of Benown.

TROOP, a small body of horse, or dragoons, usually about fifty or fixty; commanded by a captain, captain-deutenant, cornet, quarter-maister, and three or four corporals, who are the lowest officers in a troop; answering to a company of foot.

TROOPER, Independent, is a troop that is not embodied in, or joined with, any regiment.

TROOPER, To beat the, is the fame with beating the assembly.

TROOPERS of the Household. See Household.

TROOP-SHIP, is generally used to conduct troops from one place to another.

TROOPER, in the Military Art, a private man in a troop of horfe.

TROPÆA, in Mythology, a name given to Juno, because she was thought to preside over triumphs; and in thefe ceremonies facrifices were offered to her.

TROPEA, in Ancient Geography, a town of Italy, in Bruttium, towards the west. As the name signifies a trophy, it is thought that the place affirmed it after a victory gained here by Sextus Pompeius.

TROPEA DRUFT, a town of Germany, according to Ptolemy, situated between the Sala and the Rhine, in the place where Drufus died; though this fact is questioned on the authority of Dion Cassius, i. xiv. Tacitus reports that it was the place where Tiberi us was failed emperor by the Roman army. The Romans were accustomed, after their victory, to raise a trophy, confulting of the arms of the vanquished, and to inscribe on its base the names of all the nations which had participated in the defeat; and in process of time this trophy became a town.

TROPEA POLLUX, or Trophies of Pollux, were situated in Sparta, beyond the temple of Efealupius, according to Paufanias, who adds, that Pollux erected them after a victory which he gained over Lynceus.

TROPEA POMPEI, a name given to a monument erected by Pompey, after having terminated the war of Spain against Sertorius, upon which he caused to be inscribed, according to Pliny, that from the Alps to the extremity of Farther Spain, he had subdued 876 towns. This monument was adorned with the spoils which had been preserved, and on this account Strabo (l. iii. p. 156.) designates it by the term ἀργυροῦ φιλίας. It was situated on the way which entered Spain by the plain of Juncaria, at the distance of sixty-three miles from Narbonne.

TROPEA ROMANUM OR SYLVA, the trophies of the Romans and of Sylla, were erected by the Romans and by Sylla on the plain of Cheronza, in Boetia, to commemorate a victory obtained over Taxilus, general of the army of Mithridates. Paufanias.

TROPEA, a town of the Peloponnesus, in Arcadia, upon the route from Porphos to Telphusa, to the left of Ladon, and near the wood called Aphrodiasium. Paufanias.

TROPEA AUGUSTA, or TROPEA AUGUSTA, a town of Italy, in Lignaria, according to Ptolœmy, near Portus Herculis.

TROPEA AUGUSTUS, or Trophies of Augustus, situated near the sea, between Nice and Portus Herculis.

TROPEOLUM, in Botany, the diminutive of tropæum. Vol. XXXVI.
TROPÆOLUM.

Sp. Pl. 490. Willd. n. 5. Ait. n. 2. Curt. Mag. t. 23. (Cardamum ampliori folio, et majori flore; Feuill. Peruv. v. 3. t. 4. t. 8. f. 1. Viola indica feconda, nauturii fapore, maxima odorata; Hern. Lugd.-Bat. 628. t. 629.) —Leaves peltate, wavy, with blunt npted angles. Petals obtuse. —From the same country. Introduced into England in 1686, as appears by the manuscripts of Peter Collinson. This is now the most commonly cultivated species, seen in cuttings and green-house; as it requires, without any care, from self-sown seeds. The flowers are abundant from June till the whole plant perishes by the autumnal frosts. This species is larger than the foregoing, especially its petals, which are also much more rounded and obtuse. A daughter of Linnaeus is recorded as having observed a kind of flashing light from these flowers in an evening. We have watched for this phenomenon, but know not whether we ever perceived it, or whether our eyes were merely dazzled by the brilliancy of the colours. The seeds are hot and pungent, much used for pickles; and the flowers are often intermixed with fallad herbs, both for ornament and flavour.

There is a double-flowered perennial variety of this species, common in greenhouses, and readily increased by cuttings.

Another variety, with small jagged petals, called T. pinnatum in Andr. Repof. t. 535, and Ait. Epit. 375, came up under our inspection in a bed of the common T. majus, and having been immediately sent to Meffrs. Lee and Kennedy at Hammersmith, in 1806, was preserved, and differed by cuttings all over the kingdom. It fearfully ever attempts to form any seed, and is cultivated just like the double kind, on whole botanical history, and origin, it appears to throw considerable light.

3. T. hybridum. Male Indian-crefs or Nafturium. Linn. Mant. 64. Willd. n. 9. "Berg. Ait. Holm. for 1765. 32. t. 1." —Leaves wedge-shaped, five-lobed, entire, scarcely peltate. —A variety of the leaf, which, according to Linneaus, sprung up accidentally in a garden at Stockholm. It rarely produced seed in the Upfald garden, but was propagated by cuttings. A seedling plant however is preferred in the Linnean herbarium. The leaves are palmate, but wedge-shaped at the base, deflexed, on very long slender footstalks, whose inflorescence is quite at the bottom, nor do we find a single leaf in any degree of a petal. The nectar is fast to be obtuse; the corolla scarcely ever of any determinate form. We retain this as a species, merely in conformity to our predecessors. Its history is presumed to be authentic; but a few varieties are more extraordinary.

4. T. peregrinum. Fringed Indian-crefs or Nafturium. Linn. Syst. Nat. ed. 10. v. 2. 998. Mant. 2. 371. Hellen. Diff. 19. Willd. n. 4, excluding the synonym of Jacquin, and perhaps of Feuillée. —Leaves peltate, palmate, deeply five-lobed. Petals all jagged and fringed. Nectaris flatly, about twice the length of the corolla. —Native of New Granada, from whence it was sent by Mutis and his pupils to Linnaeus, who also received a garden specimen from his friend Duchesne. This species is not known in England. The leaves are all slightly, but uniformly, peltate, with five, rarely seven, deep lobes, various in breadth and acuteness, the middle one sometimes three-cleft, the two next occasionally having a lateral external lobe. Flowers rather smaller than in T. minus, though the nectar is as long, and of the same taper form, scarcely curved, and by no means hooked. Petals unequal in size, all deeply and irregularly laminated, with fine capillary segments. We find these segments variable in breadth, like the foliage, in our numerous native specimens, but their general aspect is the same. Lamarc's t. 277. f. 3, represents this plant. Feuillée's plate and description, if good for any thing, must belong to a different species, or variety, three of whose petals are very small, and quite entire. His nectar is too imperfectly drawn for us to determine any character from thence. We have seen in the foregoing species how liable the petals are to the most extraordinary variation, so that we dare not, from Feuillée's figure alone, attempt to define him as a distinct species.

5. T. advena. Hooked Indian-crefs or Nafturium. Sm. Tour on the Continent, ed. 1. v. 1. 158. ed. 2. v. 1. 165. (T. peregrinum; Willd. n. 4. Ait. n. 3. Jacq. Hort. Schoenbr. v. 1. 51. t. 98. Andr. Repof. t. 617. Curt. Mag. t. 1351.) —Leaves peltate, palmate, deeply five-lobed. Two petals jagged; three smaller fringed. Nectaris hooked, the length of the larger petals. —Native of Peru. Cultivated in the open air at Gibraltar, where it is called the Canary-bird flower, and perhaps in other parts of Spain. In Germany, England, and even the south of France, this is a greenhouse plant, very tender with us, and seldom ripening seed. The leaves do not much differ from the real T. peregrinum, but the flowers are coquettishly very distinct, nor do any specimens or figures, that we have seen, shew them to be variable in any degree worthy of notice. Their calyx is pale green, with a remarkably hooked spur, hardly an inch long if it could be straightened. Petals lemon-coloured; the two uppermost deeply jagged, rarely hair-pointed; three lower much smaller, oblong, undivided, copiously fringed. Jacquin's figure displays a luxuriance of foliage greater than we have met with, some leaves having seven, more or less pinnatifid, lobes. There can be no doubt of this being a very distinct species. A figure of it was drawn for the 30th plate of our Speciosiæ Botanicae, but that work never proceeded to a third fasciculus, and the figure would now be superfluous.

6. T. pentaphyllum. Five-leaved Indian-crefs or Nafturium. Lamarcch. Diff. v. 1. 612. Illufr. t. 277. f. 2. Willd. n. 5. (T. quinatum; Hellen. Diff. 20. t. 1.) —Leaves quinate; leaflets ovate, entire, falked. Petals undivided, shorter than the segments of the calyx. —Gathered by Commerfon at Buenos Ayres, where this elegant and singular species climbs amongst Indian figs, and other shrubs, according to a manuscript note before us. The stem is slender, clothed with numerous, irregularly scattered, leaves, on footstalks: an inch or an inch and a half long; leaflets on short partial stalks, acute, all undivided; the central one an inch in length; the two nearest the stalk not half so large. Flowers numerous, folicular, on axillary stalks extending rather beyond the leaves. Tube of the calyx above an inch long, conical, deep orange-coloured, contracted towards the end, which is oval; segments about a quarter as long, ovate, acute, green towards the point, two of them prominent, and rather larger than the rest. Petals not discernible in the flowers we have examined. Professor Hellenius describes them "ovate, entire, nearly sessile, a quarter the length of the segments of the calyx," which answers to Lamarc's definition.

Three more species of this genus are described in the Flora Peruviana, one of them having only two petals; but of these no specimens have fallen under our inspection.

TROPÆOLUM, in Gardening, furnishes plants of the herbaceous, annual, and perennial, trailing and climbing kinds, among which the species cultivated are the small Indian crefs or nafturium (T. minus); and the great Indian crefs or nafturium (T. majus).

In the first sort, there are varieties with deep orange-coloured flowers inclined to red, with pale yellow flowers, and with double flowers.

And in the second kind, there are varieties with pale yellow
yellow flowers, orange-coloured flowers, and the double-flowered.

It may be noticed that they are both natives of Peru, and commonly esteemed to be annual plants, though they may be continued through the winter, if they are kept in pots, and sheltered in a greenhouse or glass-cave, in the same manner as the variety with double flowers.

The flasks will climb fix or eight feet high, when they are trained up, and thus the flowers make a good appearance; but when they trail upon the ground, they will spread over the neighbouring plants and become unhappily: the flowers are frequently eaten in salads; they have a warm taste, like the garden cress, and hence the plant has its common name naffurtium; they are likewise used for garnishing dishes: the seeds are pickled, and by some are preferred to most pickles for sauce, under the false name of capers.

Method of Culture.—These plants, in all the single varieties, may be increased by seeds, which should be sown in the spring in patches where they are to flower in the borders, or in drills in the garden.

They afterwards only require to be kept free from weeds, and to be well supported by sticks.

The double variety must be increased by planting cuttings of the branches in pots of light mould in the early part of the summer, placing them in the shade, and giving frequent light waterings, but not too freely in the winter months: those planted early may be rendered more forward by being plunged in a moderate hot-bed.

It requires to be protected in the greenhouse in the winter, being well supported with sticks.

Both the sorts are cultivated in the garden as flowering plants, and for culinary use in salads and pickles, being often in the former view trained against fences and walls, or to run on trellises, railing, palings, hedges, the sides of arbours, and some other kinds of supports. Also to run on branches sticks set in the borders and other parts.

In the latter intention, the common single sorts and varieties are often grown, which supply young tender leaves and berries that are much esteemed by some for the purpose of eating, the former as a warm relishing agreeable fallad article, and the latter as a very pleasant sort of pickle while young and fresh. The flowers are also warm in their taste, and afford a very ornamental garnish, in many cafes, both for fallad dishes and those of the meat kind. When the plants are raised in these views, the seeds should be sown in the small compartments of the kitchen garden to the later spring months, in small patches or shallow drills to the depth of an inch, and the plants when up have the support of a few branchy sticks, by which means they afford supplies in each of these ways for two or three months.

They all afford variety in the borders, clumps, &c. in the summer, and the double sorts among potted plants.

TROPÆUM Q. Fabii Maximi Epsidionis, the trophies of Fabius, &c. in Ancient Geography, were situated, according to Strabo, near the place where the Iere discharges itself into the Rhine, and on this spot 30,000 Romans, commanded by Fabius, defeated 200,000 Gauls, in commemoration of which, the general caused to be erected on the field of battle a trophy of white stone.

TROPEUS, in Mythology, a name given to Jupiter, for the fame reason that Tropæa was given to Juno.

TROPATENA, in Ancient Geography, a country of Asia, extending, according to Ptolemy, from the territory of the Celi-Marephi to that of the Amaranii.

TROPE. Tropus, in Rhetorice, a word or expression used in a different fene from what it properly signifies.—

Or, a word changed from its proper and natural significations to another, with some advantage.

As when we say an afo, for a fluid person; thunder-bolt of war, for a great captain; to wash the blackamoor white, for a fruitless undertaking.

This change of fene is never to be used, but where it gives a force and dignity, or renders the discurso more significant, weighty, and graceful.

It is called trope, τρωπός, from the Greek, τρυπετος, ςυρβ, 1 change; because the words are here transferred from the things they properly import, to others which they only import indirectly: and that tropes only signify the things they are applied to, by reason of the connection and relation those things have with those others, whose proper names they are.

This change, or inversion, is performed various ways; but chiefly four: whence arise four principal tropes; viz. the Metaphor, Metonymy, Synecdoche, and Irony; which see respectively.

Some authors confound trope with figure; but they are very different things. Moliére authors, as F. de Colonia, &c. make figure the genius, and trope a species; defining figure to be, an ornament in discourse, by which it is raised above the common language; and trope to be that peculiar kind of ornament which confines in the change of the fene, &c. But Voltaire makes trope and figure to be two collateral and independent things; defining trope to be the change of the fene, &c. and figure to be any ornament, except what becomes fo by such change, &c. See Figure.

With regard to the difference between tropes and figures we may observe, that tropes mostly affect single words, but figures whole sentences: a trope conveys two ideas to the mind by means of one word; but a figure throws the sentence into a different form from the common and usual manner of expression; and besides, tropes are chiefly designed to represent our thoughts, but figures our passions. The reaons which have occasioned the introduction of tropes are, according to Quinncilian, three: viz. necessity, emphasis, and beauty. Tropes were first introduced from necessity, because no language contains a sufficient number of proper words to express all the different conceptions of our minds. Tropes do also on many occasions express things with greater force and evidence than can be done by proper words; thus when Virgil (Aen. lib. vi. v. 842.) calls the Scipios two thunder-bolts of war, he gives us a more lively image of the rapid force and speedy success of their arms, than could have been conveyed by a long description in plain words. And moreover, beauty and ornament have been another cause of the use of tropes; and it is the business of an orator to entertain his hearers, at the same time that he instructs them. Accordingly some subjects require a more florid and elegant address than others, and variety of expression is also pleasing in a discourse.

The following directions, however, are proper to be observed in the choice of tropes. As every trope gives us two ideas, one of the word expressed, and another which by means of that the mind connects with it; it is necessary that the relation between these two should appear very plain and evident; for an obscure trope is always faulty, unless where some particular reason makes it necessary; and therefore tropes ought not to be too far-fetched, lest they should thus be rendered obscure. Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so as neither to heighten nor diminish the just idea of it. Poets, however, are allowed a greater liberty in this respect than orators. Further, as a moderate use of tropes, judiciously applied,
beauties and enlivens a discourse, so an excess of them causes obscurity, by running it into abitrude allegories and riddles. Moreover, as one use of tropes is pleasure and entertainment, we should endeavour to make use of such as are smooth and easy: and if it should be necessary to use a harsh trope, it is proper to soften it by some precaution. Finally, care should be taken how we transfer tropes from one language into another. It was customary for the Roman soldiers to carry their money in their girdles; hence it was the same thing with them to say, a perfan had left his girdle (Hor. Ep. lib. ii. cp. 1.), as that he had left his money. And because the Romans wore the toga in time of peace, and a different garb when engaged in war, their writers sometimes use the word toga to signify peace. But as neither of these customs is in use among us, nor whether the tropes fuit our language, or be generally understood by us. There is also a beautiful trope in the account of St. Paul's shipwreck, in the use of the word ἀντείθησαμαι (Acts, ch. xxvii. v. 15.) which we translate to bear up into the wind, but which properly signifies to look or keep its eyes against it; to this purpose Plutarch fays of Demosthenes, that he could not ἀντείθησαμαι τω αὐχένιοι, look against or resist the power of money. Ward's Orat. vol. i. lect. 25. See also on this subject, Blake's Lect. vol. i. lect. 1.

Besides the four capital tropes above-mentioned, there are several inferior ones. When the trope is too bold, it is called an hyperbole; when continued, it is an allegory; when too obscure, an enigma; when it shocks us, or is too remote, a catachresis.

Add to these, other tropes: as the metalepsis, autonomania, and litotes, or extinction. See Metaphor, &c.

Some also refer the five kinds of scoffing, or derision, to the tropes; viz. the farcasm, diafyrax, charitienfim, alphem, myterifim, and mimefs; but this without sufficient reason.

See Sarcasm, Irony, &c.

TROPEA, in Geography, a town of Naples, in Calabria. Ultra, built on a rock near the sea-coast, the fee of a bishop, suffragan of Reggio. It contains five parish-churches, eleven convents, and about 4000 inhabitants, of whom the most wealthy and the handiersmen refide within the walls, whilst the husbandmen and labourers dwell in the outkirts, on the lands which they cultivate. Its situation is admirable, on the point of a lofty rock impending over the sea, and joined to the main land by an illusmus that is almost cut through at the gates, and thus leaves only a small passage to the town. A little to the N. lies a large island, on which some houses are turned to grace, and a small one, with a hermitage placed on its summit, in a most romantic position. The streets of Tropea are narrow, the houses high, and built of stone, with great solidity. Two gates give admittance, one to those who come up the hill from the bay, and the other to such as approach along the high plain, on which is a pleasant walk near two miles long. This level is half a mile broad between the sea and a chain of mountains so steep and rugged, that they apparently cut off all communication by land with the rest of Calabria. The whole flat, and fides of the hills, yield abundance of grapes, mulberries, olives, pulse, vegetables, and garden-fruit. Copious streams run from the mountains, and after watering the orchards, are collected into one body, and turn a great number of mills. In 1783, it suffered greatly from an earthquake; 37 miles N.N.E. of Reggio. N. lat. 35° 40'. E. long. 16° 13'.

TROPER, in our Old Writers, is used for a book of alternate turns and refpones in finging mafs. Lindcwoode calls it fiber fegmentarium.

Female on a separate tree, Cal. inferior, of one leaf, un- divided or two-lobed. Cor. either wanting, or of four con- cave, roundifh petals, closely embracing the germen. Pet. Germin ovate, of four cells; style short, thread-shaped; stigma two, awl-shaped, spreading. Peric. Berry nearly globular, corrugated, of one cell. Seeds from one to four, roundifh, with a brittle skin.

Obf. Nothing can be more obscure or uncertain than the history of this genus, nor do we feel, by any means, confident that the plants assembled under it agree in natural, or effential, characters. We must content ourselves with giving the best account of them in our power, after having so far new-modelled the generic character as to avoid palpable contradictions.

1. T. americana. Ramnoon Tree of Jamaica, or West Indian Trophis. Linn. Sp. Pl. 1451. Am. Acad. v. 5. 410. Wild. n. 1. Ait. n. 1. Swartz Obs. 372. T. folis oblongo-ovalis glabris alternis, floribus mafculinis pia- catis ad albas; Bowrme Lam. 357. f. 37. t. 1. Bucephalon racemofum; Linn. Sp. Pl. 1661. B. fructu racemofo rubro; Plum. Ic. t. 55. f. 17. —Thorns none. Leaves ovate, pointed, entire, smooth. Berry oval, furrowed, with a fimple point, and foliary feed.—Native of dry exposed situations in the West Indies, flowering in spring. Swarts. A tree, about twenty feet high. Leaves alternate, on shortifh furrowed falks; rounded at the bafe; about four inches long, with one rib and several transversef interbranching reticulated veins. Spikes axillary, falked, foliary, many-flowered, much shorter than the leaves, fome- times what downy, pale; the femina ones fhorter. Berries fpiked, felfie the size of large grapes, oval, with four furrows, and of a pleafant flavour. Swarts fay, the trunk and branches, when wounded, difcharge a very white, vifeid, milky juice. He, as well as Bowrme, affert the foliage and young shoots to afford an agreeable wholesome fodder for all sorts of cattle.

2. T. laurifolia. Laurel-leaved Trophis. Wild. n. 2. —Thorns none. Leaves elliptic-oblone, acute at each end, fmoother, entire. Berry with two horns, and two or four feds.—Native of Quito and New Granada. A tree, with thick, nearly round, branches. Leaves alternate, falked, three inches or more in length, tapering at each end, cori- ceous, smooth on both fides; thinning above; pale beneath. Clufiers axillary, the length of the footfolds. Fruit glo- bose, crowned with two dilatant, awl-shaped, inflexed horns, rather longer than the fruit itself. Seeds obovate; two only, according to Wildenow; four in a drawing lent by Mutis to Linnaeus, which the latter has marked Bucephalon, and which answers fo exactly to Wildenow's defcription of the plant gathered in Quito by Humboldt and Bonpland, that we can have no doubt of its being done from the fame fpecies. In contemplating Wildenow's specific characters of
of this and the foregoing, we cannot help thinking that he
took for the fruit of *T. americana*, the nut of *Trapa bicornis*,
(see *Trapa*,) which Burmann has subjoined to Plumer's
* t. 67.

Wildl. Sp. Pl. n. 3. * Ait. n. 2. — Thorns none. Leaves
ovate, unequally ferrated, very rough on both sides. Petals four in all the flowers.—Native of woods and
thickets at Tranquebar, flowering in April, from whence we
received specimens from the Rev. Dr. Rottler, in 1799.
*Branches* round, subdivided, leafy, without thorns or
prickles; slightly downy or hairy when young, and of a
rusty hue. *Leaves acute,* an inch long, on very short flacks;
strongly veined; ferrated beyond the middle; wedge-
shaped and entire at the base; rough on both sides like a
file, with minute callous warts: hence they serve to polish
fine cabinet-work. *Male flowers* five or eight, in axillary,
foliaceous, globose, filacted heads, sometimes accompanied by
a small rusty *bractea*, in the middle, or at the base, of the
*Stamen* four, thread-shaped, longer than the corolla, with
ovate, furrowed *anthers*. *Female flowers* two or three togeth-
er, axillary, on flacks like that of the male heads. *Calyx*
deply divided into two rounded, concave, permanent
segments, much shorter than the corolla. *Petals* four, ovate,
or nearly orbicular, concave,downy, closely invilging the
german, permanent. *Germen ovate*. *Style* very short. *Stigma*
long and flender. *Berry orange-coloured,* smooth, somewhat
comprised, with a small portion of pulp. *Sced* one or two,
globular, the size of a pea.

4. *T. spinosa.* Thorny Trophis. Wildl. n. 4. (Cudrana-
num javanum; Rumph. *Ambib.* v. 5. 22. t. 15. f. 2.)—
Thorns thorny. Leaves elliptical, entire, smooth. —*Native
of Java. *Branches* round, greyish-brown, armed with
axillary solitary thorns, which are incurred when young,
but become subfrequently inflated. *Leaves* filacted, larger
than the leaf, and very smooth on both sides; paler beneath.
*Female flowers* two or three together, lateral, filacted.
*Male ones* not observed. The wood is used to dye yellow,
and, with the addition of indigo, green. The berries are
described by Rumphius about the size of a strawberry, with
several feels, and of a yellownish colour. By his account
also, it should seem that this fruit is invested with a permanent
hardened *carolla*, evincing the generic affinity of the present
species to the last; though their belonging to *Trophic* must,
for the present, remain very doubtful.

**TROPHONIUS, Oracle of, in Ancient Mythology,** a famous oracle in Boetia, which was consulted with greater
ceremony than those of any deity, and subfitted long after
all those of Greece ceased. Trophonius, from whom the
oracle took its name, was the son of Erginus, king of the
Orchomenians, who, as well as his brother, were famous ar-
chitects, and built the temple of Apollo at Delphi. The
tomb of Trophonius had been altogether disregarded and
forgotten, when the Boetians, on occasion of a great
drought, consulting the oracle of Apollo, were directed to
have recourse to Trophonius at Lebadea. They purfued
the direftrion of the oracle, and obtained an answer, that
fuggested the means of removing their calamity. In con-
fquence of this event, they conferred to Trophonius the
wood in which he was interred; and in this wood erected a
temple to him, with his natne executed by Praxiteles.
The oracle of Trophonius was upon a mountain, within an
eclufure of white flones, upon which are elevated obelisks
of brafa. In this enclosure there was a cavern, in the form
of an oven, cut out of the mountain by human art and
labour. Within this was another small cavern, with a very
straight entrance, into which those who consulted the oracle
were to pafs, with a variety of ceremonies.

**TROPHY, TROPEUM,** among the *Ancients*, a pile or
heap of arms of a vanquished enemy, raised by the con-
queror in the most eminent part of the field of battle.
The word is formed from the Latin *tropheum*, or *tropaeum*,
which Vellius deduces from the Greek *trophe*, the flight of
an enemy.
The word is also used for an artificial representation of
such a pile in marble, stone, or other matter. Such were
the trophies of Marius and Sylla, in the Capitol, &c.
The ancient trophies confift of Greek and Roman arms;
and the modern ones of arms of the various nations now in use:
as in thothe infufated ones near Blenheim, in the Faux-
bourg S. Antoine, and in the castle of Verfaflles. Some
are done in baffe-relevo; as thefe of the Trajan column,
and the Attic of the court of the Louvre. The form of
these trophies cannot be better defcribed than in Virgil's
second *Aeneid*. Of thothe which Marius raised after the
Cimbic war, still remaining at Rome, Fabricius has given
the following account. They are two trunks of marble
hung round with spoils; one of them is covered with a feally
confeilt, with shields and other military ornaments. Just
before it is fet a youn man in the picture of a captive, with
his hands tied behind him; and all round were winged
images of victory. The other is fet out with the common
military garb; having a shield of an unequal round, and
two helments, one open and adorned with crefts, the other
clofe, without crefts. On the fame trophy is the shape of a
foilder's coat, with several other defigns, which, by reason
of the decay of the marble, are not difcovered without
great difficulty. Thesefe trophies now adorn the front
of the Capitol.

Trophies are likewise frequently exhibited on medals of
the emperors, stuck on occasion of victories; wherein,
befides arms and spoils, are frequently feen one or two
captives by the fides of the trophy.

Trophies, M. Vaillant observes, were, originally, nothing
but trunks of trees, which the victor planted on the most
eminent part of the conquered province, and hung them
with the spoils of the enemy, to perpetuate the memory of
the defeat.

**TROPHY, in Architecture,** an ornament which represents
the trunk of a tree, charged or encompassed all round
about with arms or military weapons, both offensive and
defensive.

**Trophy Money,** a duty paid annually by the house-
keepers, in the several counties of England, towards
providing harness, drums, colours, &c. for the militia.

**TOPRIANA,** in *Ancient Geography,* a town of Italy, in
Calabria.

**TROPICS, TROPIC,** in *Astronomy,* two inimmovable
circles of the sphere, drawn through the fudificial points,
parallel to the equator.

Such are the circles *M E* and *N L.* *Plate XVI. Astron-
omy,* fig. 149.

The tropics may be defined, two circles parallel to the
equator, at fuch distance from it, as is equal to the fun's
greatest recfs from the equator towards the poles; or to
the fun's greatest declinations; or the obfolute of the
ecliptic.

Of the two tropics, that drawn through the beginning of
Canor L, is called the *tropic of Cancer.* And that through
the beginning of Capricorn, the *tropic of Capricorn*.

They have their name from the Greek *topros,* turn or
*verfion,* as being the limits of the fun's way, or declaration
towards
TRO

TROSBURG, a town of Upper Bavaria; 13 miles E.

of Wallerburg.

TROSSACHS, a tract of rugged rocks or mountains

of stupendous height, situated about 10 miles W. from Cal-

lander, in the thirne of Perth, Scotland, and accessible by a

carriage-road. They exhibit an assemblage of wildness and

rued and grandeur, which fills the most exalted and sublime

conceptions. It seems as if a vast mountain had been torn

in pieces, and frizzled down by a convulsion of the earth,

and the huge fragments of rocks, woods, and hills, scattered.

in confusion for two miles on the sides of Loch Ca-

therine. A huge column of these rocks was some years ago

torn with thunder, and lies in very large blocks near the road.

Where there is any foil their sides are covered with aged

birch-trees. The fenible horizon is bounded by these trees

on the summit of every hill. On the north side, the road is

cut in some places through the solid rock, which rises up

wards of 200 feet perpendicular above the lake; at others

the road is at the foot of lofty cliffs, and trees are growing

where no earth is to be found.—Beauties of Scotland,

TROSSULI, among the Romans, a name given by

fome to the guards that attended the kings of Rome, other-

wise called celeres.

TROSSULUM, in Ancient Geography, a town of Italy,

in Etruria, in the vicinity of the country of the Volsci,

according to Pliny.

TROT, in the Manges, one of the natural paces of a

horse, performed with two legs in the air, and two on the

ground, at the same time, crofswise, and continuing fo

alternately, to raise the hind-leg of one fide, and the fore-

leg of the other fide at once; leaving the other hind and fore-

leg upon the ground till the former come down.

This action of his legs is the fame as when he walks,

except that in the trot his motions are more quick.

In this motion, the nearer the horse takes his limbs from

the ground, the opener, the evener, and the shorter his trot

will be. If he takes up his feet flovenly, it is a sign of

fumbling and lameness; if he tread narrow, or crofs, it

betokens interfering or falling; if he tread long, it fhews

over-reaching; if he fteps uneven, he indicates toil and

wearing.

Three qualities are essenfially neceffary to make the trot

ufeful. It ought to be extended, fupper, and even or

equal; these three qualities mutually depenf upon each

other; fo that you cannot pafs to the fupper trot, without

having fift worked upon the extended trot; and you can

never arrive at the even and equal trot, without having prac-

ticed the fupper. The extended trot is that in which the

horse trots out without retaining himfelf, being quite

ftraight, and going direcfly forwards; and this, confef-

quently, is the kind of trot with which you must begin.

The fupper trot is that in which the horse, at every motion

he makes, bends and plays all his joints, viz. thefe of his

shoulders, his knees and feet, which no colts, or raw horsies,

can execute, who have not had their limbs fupplired by ex-

ercife, and who always trot with a surprifing fiftinefs and

awkwardnefs, without the leaft spring or play in their joints.

The even or equal trot is that in which the horse makes all

his limbs and joints move fo equally and expreffly, and his

legs never cover more ground one than the other, nor at

one time more than another. To do this, the horse muft

necessarily unite and collecf all his flrength, and, if the ex-

pression may be allowed, diftribute it equally through all his

joints. To go from the extended trot to the fupper, you

must gently and by degrees hold in your horse; and when

by exercife he has attained fufficient cafe and fupperlets to

manage
manage his limbs readily, you must infenfibly hold him in
still more and more, and by degrees you will lead him to
the equal trot. All horses that are inclined to be ramingque
should be kept to the extended trot. A horse of a flaggish
and cold disposition, which has, nevertheless, strength and
bottom, should likewise be put to this trot: as he grows
animated, and begins to go free, keep him together by little
and little, in order to lead him infenfibly to the fupple trot;
but if, while you keep him together, you perceive that he
flacks his action and retains himself, give him the aids
brietly, and push him forward, keeping him, nevertheless,
gently in hand: by this means he will be taught to trot
freely and equally at the same time.

The only proof, or rather the most certain sign of your
horse's trotting well is, that when he is in his trot, and you
begin to push him a little, he offers to gallop. The principal
effects of a trot are to make a horse light and active,
and to give him a just appui.
The manner of trotting a colt which has never been backed
is as follows: put a plain snaffle in his mouth; fit a cavefon
to his nose, to the ring of which tie a longe of a reasonable
length. Let a groom hold this longe, who, having got at
some distance from the colt, must fland still in the middle of
the circle which the horse will make. Let another follow
him with a long whip or chambriere in his hand. The colt,
being alarmed, will be forced to go forward, and to turn
within the length of the cord; the grooms must hold it tight
in his hand; by this means he will draw in, or towards the
centre, the head of the colt, and his croup will of consequence
be without the circle. See Foal, and Backing of a Horse.

In working a young horse after this manner, do not press
or hurry him. Let him walk first, and afterwards put him
to the trot. If you neglect this method, his legs will be
embarrassed; he will lean on one side, and be more upon
one haunch than the other; the inner fore-foot will strike
against the outer one, and the pain which this will occasion
will drive him to seek some means of defence, and make
him disobedient. If he refuses to trot, the person who
holds the chambriere will animate him, by trotting him, or
skirling the ground with it. If he offers to gallop instead of
trotting, the groom must shake or jerk the cord that is
tied to the cavefon, and he will fall into his trot. Berenger's
Art of Horsemanship, vol. i. ch. 4.

TROTHY, in Geography, a river of England, in the
county of Monmouth, which runs into the Wye, near
Monmouth.

TROTZA, a river of Russia, which runs into the
Kama, 16 miles N. of Kofa, in the government of Viatka.

TROU, Lp., a settlement in the N. part of Hifpaniola.
N. lat. 19° 35'. W. long. 72°.

TROUBADOURS, a name given to the ancient poets
of Provence, who wrote, set, and sung their own verses.
See Provencal Poets.

Some will have the word borrowed from Trouver, to find,
by reason of their inventions, whence they are called Trou-
verets; though others take them to have been called Tromba-
dours; by reason they sung their poems to an instrument
called a tromp or trampe.

The poetry of the troubadours confisled in sonnets, pa-
torals, fongs, fyrvantes, or fatires, which were much to their
taff; and in tenfons, which were love-diputes.

Jean De Notre Dame, commonly called Nofradosorus, a
procureur in the parliament of Provence, wrote an amble
discourse of these poets. He makes their number seventy-
fix.

Pasquier tells us, he had an extract of an ancient book,
belonging to cardinal Bembo, entitled "Los Noma da-
ques qui sirent Tenfons & Syrventes," which made their
number ninety-six; among which was an emperor, viz.
Frederic I. and two kings, viz. Richard I. of England, and
a king of Arragon; with a dauphin, several counts, &c.
not that all these had composd entire works in Provencal;
some of them had not brought forth any thing beyond
epigrams.

Petrarch speaks, with applause, of several troubadours
in the fourth chapter of the Triumph of Love. The Ita-
lion poets are said to have borrowed their best pieces from
the troubadours. Pasquier expresses, that Dante and Petrarcl are,
indeed, the fountains of Italian poetry: but fountains which have their sources in the Provencal poetry.

Bouche, in his History of Provence, relates that, about
the middle of the twelfth century, the troubadours began
to be esteemed throughout Europe; and that their credit
and poetry were at the highest about the middle of the four-
tenth. So that they flourished in Europe about two hun-
dred and fifty years, viz. from 1120 or 1130 till the year
1382. He adds, that it was in Provence that Petrarch
learned the art of rhyming, which he afterwards praticed,
and taught in Italy.

Strolling musicians, under the appellation of Jongleurs,
(which fee,) abounded in France so early as the time of
Charlemagne, who forbids their admission into convents;
and in the first capulatory of Aix-la-Chapelle, this prince
speaks of them as perfons branded with infamy. They
continued, however, to amufe the great in private, as well as
the people in public, as a distinct body of men, till the trou-
badours introduced poetry into France, in the dislext of
that country. Their licentiousness was frequently re-
prefed, and their conduct regulated, by the police; and
during the reign of Philip Augustus, the troubadours and
minstreles, or jongleurs, were involved in the fame disgrace,
and for some time banished the kingdom; which fettuch
a stigma upon their order, as no efforts of genius, or aulte-
riety of manners, could entirely efface, though they were
afterwards recalled, and in some degree restored to publir
favour.

It is observed by a late elegant French writer, that though
the profcription of music and poetry, and the kind of
inquisition which Philip etablifhed against the jongleurs in
France, may have originated from the laudable intention of
repressing those disorders, which the abuse of their pro-
fession had occasioned; yet, if he had reflected that the
fate of letters was at that time in the hands of the trou-
badours, and that among every people approaching towards
civilization, the progress of virtue is generally propor-
tioned to the cultivation of arts and literature, he would
have inflicted a less ignominious punishment on the objects
of his displeasure; for such is the empire of prejudice, that
the anathema it pronounces against the abuse of a profession
remains in full force, even after the reformation of those who
exercife it. This author ventures to pronounce the jong-
leurs, or troubadours and minstreles, notwithstanding the con-
tempt with which they are named at present, to have been
the fathers of literature in France: they, fays he, banished
scholastic quarrels and ill-breeding, and polished the manners,
etablifhed the rules of politeuefs, enlivened the conversa-
tion, and purified the gallantry of its inhabitants. That
urbanity, continues he, which distinguishes us from other
people, was the fruit of their fongs; and if it is not from
them we derive our virtues, they at leaft taught us how to
render them amiable. Tableau Historique de Gens des
Lettres, par l'Abbe de Longchamps, tom. vi. cited by

Mr.
Mr. T. Warton (Hift. of English Poetry) is of opinion that there were two forts of French troubadours who have not been sufficiently distinguished. If we diligently examine their history, we shall find that the poetry of the first troubadours consisted, as we have already intimated, in fat, moral fables, allegories, and sentimental fonnets. So early as the year 1180, a tribunal called the "Court of Love," was instituted both in Provence and Picardy, at which questions in gallantry were decided. This institution furnished ample matter for the poets, who threw the claims and arguments of the different parties into verse, in a style that afterwards led the way to the spiritual conversations of Cyrus and Clelia. Fontenelle does not scruple to acknowledge, that gallantry was the parent of French poetry. But to sing romantic and chivalrous adventures was a very different talent, and required very different talents. The troubadours, therefore, who composed metrical romances form a different species, and ought always to be considered separately. And this latter class seems to have commenced at a later period, not till after the crusades had effected a great change in the manners and ideas of the western world.

In the mean time, as Warton conjectures, the art of the troubadours, commonly called the "Gay Science," was first communicated from France to the Italians, and afterwards to the Spaniards. If this be true, it is at the same time highly probable, that the Spaniards had their "juglares," or convivial bards, very early, because of long connection they were intimately acquainted with the fictions of the Arabians, and were naturally fond of chivalry, that the troubadours of Provence in great measure caught this turn of fable from Spain.

The communication, without mentioning any other obvious means of intercourse, in an affair of this nature, was easy through the ports of Toulon and Marseilles, by which the two nations carried on from early times a confiant commerce. Even the French critics themselves universally allow, that the Spaniards, having learned rhyme from the Arabians, through this very channel conveyed it to Provence. Taffo preferred "Amadis de Gaul," a romance originally written in Spain by Valco Lobeyra, before the year 1300, to the most celebrated pieces of the Provençal poets. The early universality of the French language very much contributed to facilitate the circulation of the poetry of the troubadours in other countries; and thus they contributed in a very considerable degree to the revival and diffusion of literature in Europe. See Josqueurs, Minstrel, Mystery, Provençal Poets, Romance.

TROUBLES, in Geography. See Coal.

TROVE, in Law. See Treasure-Trove.

TROVER, an action which a man hath against one that, having found any of his goods, refuseth to deliver them upon demand, but converts them to his own use; from which finding and converting, it is called an action of trover and conversion.

Actions and detinue are frequently turned into actions upon the cafe, sue trover and conversion.

The injury in this cafe lies in the conversion: and, therefore, the fact of the finding, or trover, is now totally immaterial; for the plaintiff needs only satisfied (as words of form) that he lost such goods, and that the defendant found them; and if he proves that the goods are his property, and that the defendant had them in his possession, it is sufficient. But a conversion must be fully proved; and then in this action the plaintiff shall recover damages equal to the value of the thing converted, but not the thing itself; which nothing will recover but an action of detinue or replevin.

See Restitution of Stolen Goods.

TROUGH, a hollow wooden vessel for kneading dough in, or to beat apples in for cider; also a piece of the trunk of a tree made hollow, to feed hogs in; or an open pipe or channel, made of boards, for the conveyance of water.

TROUGH of the Sea, is the hollow cavity made between two waves, or hollows, in a rolling sea.

When a ship lies down there, they say, the lies in the trough of the sea; in which case the rolls heavily, because the setting of the sea is always produced by the wind, and, consequently, the waves, and the trough between them, will be at right angles with the direction of the wind.

TROUPE HEAD, in Geography, a cape of Scotland, on the north coast of the county of Banff; 10 miles W. of Kinnaird's Point. N. lat. 57° 30'. W. long. 2° 11'.

TROUPESBURGH, a township of New York, in the United States, situated in the S.W. corner of Steuben county, 25 miles S.W. of Bath village, erected in 1808, from the S. part of Canileo and a small part of Addison, and extended to Allegany county in 1811; bounded N. by Canileo, E. by Addison, formerly Middletown, S. by the county of Pennsylvania, and W. by Allegany county. It is 18 miles long E. and W., and about 10 miles wide. The population in 1810 consisted of 292 persons and 36 ferreto-electors.

TROUSSEQUEXE, in the Monde. See Dock.

TROUSSEQUIN, a piece of wood, cut archwise, raised above the hinder bow of a great faddle, and serving to keep the hollers firm.

TROUT, Salmo fario of Linnaeus, in Ichthyology, a very valuable river-fish. See Salmo Fario.

The colours of the trout, and its spots, vary greatly in different waters, and in different localities; yet each may be reduced to one species. In Llyndivi, a lake in South Wales, are trouts called cooch y dail, mentioned by Pennant. See Salmo Fario.

In Lough Neagh, in Ireland, are also trouts called buddagh, some of which weigh thirty pounds; and others of a much superior size are taken in Hurl's water, a lake in Cumberland, supposed to be the same as the trouts of the lake of Geneva. In the river Eynion, not far from Machynlleth in North Wales, and in one of the Snowdon lakes, is found a variety of trout, naturally deformed, having a strange crookedhead near the tail.

The Hon. Mr. Daines Barrington supposed, that gillaroo, the name given to certain trouts in the Irish lakes, (see Salmo Fario,) may be either a corruption of Killala, the name of a town near which these trouts are caught, or formed of the Welsh cyll, q. d. Mormach, and the Irish ruadb, q. d. strangh; so that gillaroo may be the same as strong Mormach. From the observations both of Dr. Watson and Mr. J. Hunter, there is no reason for considering the Mormach of these trouts as gizzards, but as true morachs. That of the English trout is of the same kind with the Mormach of the gillaroo trout, but its coat is not so thick by two-thirds: and, therefore, the difference in the thickness of the Mormach, which may be occasioned by the nature of the waters, or adapted to the purposes of constituting a greater quantity of shell-fish than the Mormach of our trouts, does not warrant its being classed as a distinct species. The Mormach even of the gillaroo trout can poises fearlessly any power of grinding, as the whole cavity is lined with a fine villous coat, the internal surface of which appears everywhere to be digestive, and by no means fitted for mastication.
TROWBRIDGE, in Geography, a considerable market and manufacturing town in the hundred of Melksham and county of Wilts, England; is situated at the distance of 28 miles N.W. from Salisbury, and 98 miles W. by S. from London. Neither the etymology of its name, nor the period of its origin, can be ascertained with accuracy; but as it is not mentioned in Domesday book, we may conclude that it had no existence when that work was compiled. The earliest notice of it in history occurs in the reign of king Stephen, about the year 1150, when it appears that Trowbridge castle was occupied by the partisans of the empress Maud, and was besieged and taken by Stephen; but whether there was any town at that era does not appear. It is certain, however, that the lordship of Trowbridge formed part of the estates of Henry, duke of Lancaster, whose daughter Blanche married John of Gaunt, son of Edward III. When Lancaster was constituted a county-palatine, this manor, as part of the dukes property, was recognized in the charters as one of the honors attached to it; and here it is probable the court of chancery for the duchy was held, as the rents for the same are paid at Trowbridge to this day. As the entire duchy of Lancaster was vested in the king in the reign of Henry VII., this town, as belonging thereto, became a royal demeine. In the next reign it was granted to Edward, earl of Hereford, afterwards archbishop of Canterbury, at whose attainder it again reverted to the crown. It was restored to his son by queen Elizabeth, and continued the property of his collateral descendants till the reign of Charles I., when Francis Seymour was created baron Seymour of Trowbridge. It afterwards passed to the family of Manners, by the marriage of lady Frances Seymour with John, marquis of Granby; and from him descended to the present duke of Rutland, who sold it in 1840 to Thomas Timbrell, esq.

Like the generality of manufacturing towns, Trowbridge is very irregularly built. None of the streets seem to have been formed on any regular plan, but have been constructed according as private interest or convenience suggested. Hence, though there are several handsome houses in the town, yet they appear to disadvantage from the narrowness of the streets, and the intermixtute of old and mean buildings. The extent and importance of Trowbridge may be best determined by the parliamentary report of 1811, by which it appears to have then contained 1770 houses, and 7955 inhabitants. Of the latter, the greater part was engaged in the woollen manufacture, which was first established here in the early part of the reign of Henry VIII. Leland, who lived in that reign, gives the following account of this town. "From Bradforde to Thorough-bridge, about a two mile by good corne, pasture, and wood, I enter into the town by a stone bridge of three arches. The town stands on a rokky hille, and is very well buildyd of stone, and florished by drapery. Of later tymes, one James Terumber, a very rich clothier, buildyd a notable faire house in this town, and gave it to his deth, with other landes, to the finding of two Canuaries pretes yn Thorough-bridge chyrch. This Terumber made also a little almoxe-houshe by Thoroughe-bridge chyrch, and yit it be a six poore folkes, having a threpence by the week towards their finding. Horcon, a clothier of Bradforde, buildyd of late daies dyers fine houys in this town. Old Bayllie buildyd of late in this town; he was a rich clothier; Bayllie's fun now draped yn the town, and also a two miles out of it, at a place yn the way to Fazey castel. One Alexandre is now a great clothiar in the town." The cloths now principally manufactured here are superfine broad cloths and kerseywares: the weekly produce is estimated at ninety pieces of the former, and four hundred and ninety pieces of the latter. Trowbridge not being incorporated, its government is vested in the county magistrates, who hold the petty sessions for the Trowbridge division of the hundred alternately here and at Bradford. A court-leet and a court-baron are also annually held; in the former the copyholders, tything-men, and cornets of the market are appointed. The duty of the last-mentioned officers is to inspect the provisions brought to the market, and to see that the weights and measures accord with the proper standards. The market-day is Saturday; and a fair is held annually, at which considerable quantities of woollen goods, cattle, cheese, &c. are sold. In the market-place formerly stood a flour cross, which was taken down towards the end of the last century, on the occasion of its obstructing the communication of the High-street, and injuring its appearance. It is thus noticed by Leland: "There is a fair standing place for market-men to stand on, in the harte of the town, and this is made viij square, and a pillar in the midle, as there is one made in Malmesbury far fairer than this." The church of Trowbridge, though upwards of four hundred years old, is still characterised by the appellation of New Church, which implies that another must have previously existed here. By whom the new structure was raised is not distinctly recorded; but it appears probable, that a great part of the expense was incurred by James Terumber, the rich clothier mentioned by Leland, and the remainder by other benevolent individuals connected with the town. This opinion is founded on the context of a deed of feoffment by Terumber, dated January 14, 1483, and preferred in the seale-room; by which he directs that, out of his estates therein enumerated, ten marks should be paid Volunteer. 1864, Vol. xxxvi.
paid yearly to a priest to pray for his soul, and the souls of all other benefactors whose names should be comprised in a table hanging at the high altar. Considered in an architectural point of view, this church is deserving of notice. Leland styles it "lightum and fair," and tells us that one Molines, "a man well learned," was parson there in his time. It is a spacious edifice, and conflits of a nave, chancel, two side-aisles, with chapels attached, a north and south porch, and a large tower at the west end, surmounted by a taper spire. The nave and aisles are embattled, and are ornamented with crocketed pinnacles. Both porches are unusually lofty. The nave has a flat ceiled roof, highly decorated with flowers: it is separated from the side aisles by large arcades, supported by clustered columns with ornamented capitals. Some of the windows contain fragments of painted glass, particularly the east windows of the chapels, which are large, and display seven days or lights, separated by mullions. The font is lofty, and covered with a profusion of tracery and paneling, with sculptural representations on shields, emblematical of the crucifixion. The living is a rectory, in the gift of the duke of Rutland, he having reserved the advowson when he sold the manor: the present rector is the Rev. Mr. Crabbe. This church is the only place of religious worship on the establishment in the town; but there is a chapel of ease dependent upon it at Staverton, a hamlet within the parish. Like most manufacturing towns, Trowbridge abounds with Dissenters, and consequently contains several meeting-houses. The charitable institutions in Trowbridge are an almshouse, and a school for the education of thirty boys. The former was founded by a perfon of the name of Yerbury. The school-house stands in the church-yard, near the spot where the almshouse erected and endowed by Terum was placed, which has been recently taken down, and the funds appropriated to the use of the parish poor generally. Of the cafe no part is now standing; but its site is distinguishable by the remains of the moat and valla by which it was surrounded. It is more elevated than the town, and still retains, in the appellation Court-hill, a marked allusion to its ancient appropriation. As there are no data to determine by whom the cafe was erected, fo the period of its demolition is equally uncertain; but it must have occurred previous to the reign of Henry VIII., for Leland says of it, "The cafell floode on the fourth side of the toone. It is now eene down. There was in it a feven grete treues whereof peaces of two yet flande." The cafe was formerly approached from the town by a drawbridge over the moat, which has given occasion to a plausible conjecture that the name Trowbridge is a corruption of Drawbridge, near which the retainers of the cafe might probably have built their houses in the infancy of the town. This supposition derives some support from the fact, that some of the buildings adjoining Court-hill possess considerable marks of antiquity.

Among the distinguished natives of this town is George Kears, a writer of considerable eminence in the last century. He was defended from the earnest and opulent families of the Hungerfords and Seymours. He died June 27, 1797, aged 67.

About two miles to the south-east of Trowbridge is Rowd Ashton, the seat of Richard Godolphin Long, esq., one of the present representatives of the county of Wilts. The house is large and commodious, and has lately undergone considerable alterations and improvements, under the superintendence of Jeffrey Wyatt, esq. architect. The park is extensive and well wooded.—Beauties of England and Wales, vol. xv. Wiltshire, by John Britton, F.S.A. 1815.

TROWEL. See Brick-Layer.

TROWEL, Garden, a tool of the trowel kind, which is made of iron, in a hollow or scooped form, and is an useful implement in taking up numerous forts of small plants and bulbous roots, and replanting them in pots, fowing in patches, and various other similar light works: it should be from six to twelve inches long in the plate, and half as broad, and fixed on a short handle, to hold with one hand. From its being hollowed semicircularly, it is remarkably handy in removing many forts of small plants with a ball or lump of earth whole about their roots, so as not to feel their removal; lifting several forts of bulbous flower-roots, after the flowering is past in summer; planting bulbs in patches or little clumps about the borders, as also for digging small patches in the course of relating hardy annual flower-seeds on; likewise for filling mould into small pots in planting any fort of plants, flaring the surface of the mould in pots, and thref eating them when necessary: it is also highly useful for filling in earth about plants in hot-beds, and under frames, or any small compartments where a spade cannot be readily introduced.

They should be had of different sizes to suit different purposes.

TROWERT ISLAND, in Geography, a small island in the East Indian sea, near the south coast of Java. N. lat. " 72' 2'.

TROWERYN, a river of North Wales, which rises from a lake in Merionethshire, and runs into the Dee.

TROWLE, or TROLE, the Bowl, in English Antiquity, was a common phrase in drinking for paifing the vessel about, as appears from several of our old catches.

TROWSERS, among Sailors, a fort of loose breeches of canvas, worn by seamen, &c.

PROXIMON, in Botany, from τραχύς, catabile, a name chosen by Gartner, without much propriety, for this genus, which he very fully distinguished from Tragopogon: for that article, as well as Arnopogon, theretofore subjoined.

Gen. Ch. Common Calyx simple, ovate, of numerous lanceolate equal scales, in two rows. Cor. compound, imbricated, uniform. Florets various in number, all perfect, of one petal, ligulate, longer than the calyx, abruptly, with five teeth. Stam. Filaments, in each floret, five, capillary; others united into a long furrowed tube. Pijf. Germin, in each floret, oblong; ifyle thread-shaped, the length of the flamen; iligmas two, revolute. Peric. none, except the permanent, finally spreading, calyx. Seeds solitary, oblong, slender; down felty, capillary, roughish. Recap. naked, dotted.

Efl. Ch. Receptacle naked, dotted. Calyx of several leaves, in a double series. Seed-down simple, felty.

Obl. We do not find the calyx ever "imbricated with unequal scales," as the other says, it sometimes is. Such a character belongs to Sonchus. Neither is it perfectly simple; for, as far as we can discern in every known species, the scales, or leaves, stand in a double row, or circle, or the outer ones alternate with, and overlapping the inner, at their base. The simple seed-down essentially distinguishes this genus from Tragopogon, nor are the habits of the plants similar.

—Native
TRU

TRO

—Native of the banks of the Missouri. Biennial, with bright-yellow flowers. Pursh. Dr. Sims says perennial.

The original species was first by Clayton from Virginia, in 1794, to Gronovius, who communicated it to Linnaeus, inscribed "Dandelion with undivided leaves." Hence the latter took his specific name, the meaning of which he probably did not investigate, and he might perhaps call it Dandelion! The name is, at any rate, as bad as can possibly be, and we are happy in getting rid of it, by discovering the plant to be Mr. Pursh's first species of Traxion. Of this indeed neither this author, nor any one else, was aware; but though we have seen no specimen from Mr. Pursh, his specific character leaves no doubt in our mind, and Garret originally suggested that this Linnean Tragopogon was a Traxion. The leaves are radical, glaucous, very smooth, even, quite entire, four or five inches long, taper-pointed, with a solitary midrib, and some fine longitudinal veins. Flower-flats half as long in our specimen, but they probably are incomplete; Gronovius says twice as long; as they are fimbly, clothed in the upper part with prominent, tawny, glandular bristles, most crowded just under the flower, which is yellow, above an inch wide. Calyx smooth and glaucous, shorter than the corolla, its leaves folding over another as described in our generic character, but of equal length, not truly imbricated. The point of each is pale, a little dilated and membranous, or, as Pursh says, cupulata. Seed-down fimbly, and rough, not feathery. Gronovius rightly noted this circumstance. We can scarcely doubt the figure in Curtis's Magazine being our plant, though a larger specimen. The roughness of the flower-flats indeed is wanting, and the points of the calyx not fimbly.

1. T. lanatus. Woolly Traxion. (Tragopogon lanatus; Linn. Sp. Pl. 1. 111. Willd. Sp. Pl. v. 3. 1895. Leontodon lanatus; Linn. Am. Acad. v. 4. 287; excluding the reference to Rauwolf, 171, 217, which rather belongs to Scorzoner a tuberosa; see that article, n. 12.)—Leaves linear-lanceolate, undulated, clothed with fimbry hairs, as well as the radical flower-flats and calyx.—Native of Palestine, from whence, if we mistake not, the Linnean specimen was brought by Hasselquist. The root has a perennial aëritis, its crown bearing several tufts of upright, narrow, fheathing leaves, three or four inches long, considerably undulated, entire, loosely clothed, on both fides, with long, soft, fheagry, woolly, or rather fikly, hairs: the fapes of the outer ones pale, dilated, membranous and smooth. Flower-flats radical, folidary, from the centre of each tuft of leaves, and rather exceeding them in height, angular, covered with fmal hairs to those of the foliage. Flowers folidary, erect, yellow, nearly the size of the lift, but with fewer florets. Calyx hardly fo long as the corolla, very fheagry at the base, its leaves eight or ten, in two rows, lanceolate, smooth, bright, hairy, somewhat membranous at the edges. We can jufly perceive, in the flowers, that the seed-down is fimple and rough. Garret has indicated the true genius of this species, as well as of the foregoing. It appears nearly related to Scorzoner a tuberosa, a plant we have never seen; but whose pube feness is not deferialized as at all like that before us; and the recurved or revolute points of its calyx-fides, which moreover are unequal, and truly imbricated, in Pallas's figure, remove all ambiguity.

3. T. virginicum. Virginian Branching Traxion. Pursh n. 2. (Tragopogon virginicum; Linn. Sp. Pl. 1. 111. Hyoscyamus prenanthodes; Willd. Sp. Pl. v. 3. 1615. H. amplexicaulis; Michaux Boreal.-Amer. v. 2. 87.)—Smooth and glaucous. Stems erect, somewhat leaves, with several flowers. In meadows and moist shady woods, from Pennsylvania to Carolina. Root perennial. Herb about a foot high, with handsome yellow flowers. Pursh. The radical flowers are either obvate or fyrate, obtuse, wavy or toothed, tapering down into fheathing membranous foonfllats, together with which they measure about four inches: those of the stem few, obvate-oblong, fheagry, fheathing, the uppermost diminished to one or two bracteas, at the base of the long partial flower-flats, three or four of which together compose a fort of umbel. Flowers erect. Calyx of eight or ten glaucous smooth leaves, half an inch in length. Florets twice as long, not very numerous. Seeda few, smooth. Receptacle small, dotted, naked.—Specimens from Kalm and others from the late Dr. Muhlenberg differ widely in their foliage, that of the former being deeply fyrate, the latter fearely toothed; yet the plants are fo alike in other respects, that we cannot, without further information, diftinguish them as species.

4. T. cuspidatum. Pointed-scaled Traxion. Pursh 742. "Stalk radical, fingle-flowered; rather downy in the upper part. Leaves linear, downy and wavy in the margin. Calyx-scales imbricated, pointed, smooth."—Found by Mr. Bradbury, in Upper Louisiana. Perennial. Flowers large, yellow. Resembles T. glaucum. Pursh. By the specific character, we should be inclined to fuppute this might be the Leontodon Dandelion of Linneus, our first species of Traction, were not the fice of the flowers against it.

TROY, or ILIUM, in Ancient Geography, a cit of Troas, or Pherigmia Minor (which fee), rendered immortal by the inimitable poems of Homer and Virgil, was built by Tros, king of that country, who called it Troy from his own name, and Ilium from that of his son Ilius. It was feated on a rifing ground near mount Ida, and about five miles from the shore. Of this city, there fubfifted fearely any remains in the time of Strabo; and molt of the ancient as well as modern writers have confounded the old and new Ilium. The new city, built nearer the sea-coaf, was reduced to a village in the time of Alexander the Great, and was remarkable for nothing but a temple of Minerva, which that prince vifited, after having defeated Darius on the banks of the Granicus, and enriched with offerings, beftowing ample privileges on the place, and honouring it with the title of city. He likewise ordered the buildings to be repaired, and the whole city to be embellished by Lyfimachus, one of his generals, who surrounded it with a wall of forty furlongs in circumference. It was again reduced to the condition of an inconsiderable village, when the Romans firit entered Asia. As they pretended to be the genuine offspring of the ancient Trojans, no cost for pains were spared to reftore it to its ancient luftre, especially in the time of the Caesars. Augustus fent thither a colony, embellifhed the city with many flately buildings, and enriched it with ample privileges and exemptions. Bellonius tells us, that in his time two walls were yet standing, with the ruinous monuments of their turrets; and that he spent four hours in compaffing them, partly on horseback and partly on foot. He observed round the walls a great number of marble tombs of exquisite workmanship, with their covers entire. Two of these were still remaining when M. Spon vifited those places: who informs us, that they were in the fyle of the ancient Romans, and not unlike those that are to be feen at Arles; whence he concludes them to be the remains of that Troy which was rebuilt by the Romans. Bellonius likewise observed the ruins of three great towers, one on the top of a hill not far from the fhor, another about the middle, and the third at the bottom, with a great many large cihens to receive the rain-water. Spon observed on the south of the faven three columns lying among the briers, of which two were entire, and each of one fingle piece, being thirty
The town of Ilium, or Troy, was fortified by Laomedon, the successor of Ilus, with walls of such uncommon strength, that, in the language and belief of the times, they were deemed the work of the gods. It is said that he was assisted by Apollo and Neptune, or that he carried on and accomplished this great work with the treasures that were consecrated to them and lodged in their temples, which he plundered. It is certain, however, that the guilt of Laomedon was believed to entail calamity on his unhappy descendants. His son Priam, who attained old age in the undisturbed possession of a throne, surrounded by a numerous family, beloved by his subjects, and respected by his neighbours, was defined to feel the sharpest pangs of human misery, in a long protracted war and siege, the causes of which are thus detailed by one of the modern historians of ancient Greece.

Hereditary feuds subsisted between the ancestors of Priam and those of Agamemnon, when the latter quitted their establishments in Asia, to seek new settlements in Greece. The infults offered to Ganymede, a beautiful Trojan youth, by the brutal fury of Tantalus, was retorted on Menelaus, the fourth in descent from this infamous prince, by the rape and detention of his queen, the celebrated Helen. Paris, the ill-fated son of Priam, was the author of this new injury. But resentment for the wrongs of his house formed not the only motive which engaged the youthful levity of Paris to dishonour the sister-in-law of Agamemnon. Helen was the daughter of Tyndareus, king of Sparta. The illustrious honours of her family were adorned by the generous magnanimity of her brothers, Caflor and Polydeuces, whose exploits shone conspicuous in all the military expeditions of that gallant age. But the native bittre of Helen needed not the aid of foreign ornament. Even in the tender age of childhood, her opening charms had inflamed the heart of Theseus, the most admired and the most virtuous of the Greek chiefs. The fame of her beauty increased with her ripening age, and her person became an object of eager contention among those who, by birth or merit, were entitled to aspire at the invaluable prize. Tyndareus, solicitous to prevent the violence of a second lover (for, agreeably to the manners of his age, Theseus had carried her off by force), bound the various suitors by oath to defend the honour of his daughter, and to secure the possession of her charms to the man who should be honoured with her choice. The princely men and insatiable men of Menelaus, were preferred to the more solid qualities of his numerous competitors. Having married the heiress of Tyndareus, he succeeded, in her right, to the Spartan throne. The graceful pair not long enjoyed the honours of royalty, and the favours of conjugal union, when their happiness was interrupted by the arrival of the son of Priam, the handsome man of his age, and singularly adorned with the frivolous accomplishments that often captivate the weaknesses of a female mind. Though a soldier of no great renown, Paris had strongly imbued the romantic spirit of gallantry, which prevailed in the heroic ages, and was distinguished by an ardent passion for beauty, which, notwithstanding the general softness of his unwarlike character, prompted him to brave every danger in pursuit of his favourite object. Animated by the hope of beholding the inimitable model of what he most adored, he seized the opportunity afforded him by a voyage of Menelaus into Crete, visited the dominions of his hereditary enemies, and solicited the rites of hospitality at the Spartan court.

His person, his accomplishments, his address, and still more the voluntary hardships which he had endured for her sake, seduced the inconstant affections of the Grecian queen. Enamoured of the elegant stranger, she abandoned her country and her husband, and having transported her most valuable treasure within the Trojan walls, defied the remonstrance of Greece, and the vengeance of heaven.

It was now the time for Menelaus to crave the ripulated assistance of his ancient rivals. His demand was enforced by the authority of Agamemnon. At the summons of the two brothers, the confederates assembled at Aegium, the capital of Achaia; confirmed the obligation of their former promise; felt the proportion of troops to be raised by each prince; determined the time and place of their departure; and named Agamemnon, the most powerful among them, to the chief command, in an expedition which so deeply concerned the honour of his family.

Aulis, a fea-port of Boeotia, was appointed for the place of rendezvous and disembarkation. Before the whole army fanned from thence, Ulysses, king of Ithaca, and, what may seem extraordinary, the injured Menelaus, undertook a solemn embassy to Troy, in order to demand reparation and reparation; but returned highly disgruntled with their reception and treatment. Some members of the Trojan council had the barbarity to propose putting them to death. Their just indignation incited the warlike ardour of their associates. But contrary winds long retarded their departure. The Trojans had time to strengthen their ramparts, to collect arms and provisions, and to summon the assistance of their distant allies. The martial spirit of the age, together with a sense of common danger, brought many powerful auxiliaries; Priam's son was defended by the hardy mountaineers, who covered the back of his kingdom, by the Carians, Lycians, and other nations of Asia Minor, extending from the mouth of the river Halys to the southern extremity of Cilicia; and by the Pelasgi, Thracians, and Peonians, fierce barbarians who inhabited the European side of the Hellepont and Propontis. Confiding, however, rather in their domestic strength, than in foreign assistance, the Trojans determined to defend their native shores against hostile invasion. The debarkation of the Greeks was purchased by much blood. Having effected a defcent, they encamped on the Trojan plain, but left the only opportunity which they enjoyed, during many years, of crushing at once the power of their enemies; who immediately flung themselves up within their impenetrable walls, leaving the city open only on the side of mount Ida, from which they received corn, cattle, and other necessary supplies.

Agamemnon, as there was reason to expect from the manners of his age, had been more inglorious in collecting a great army, than provident in contriving means by which it might keep the field. The provisions, transported from Greece, were speedily consumed, while the operations of the siege...
TROY.

The siege promised little hopes of success, the Greeks being unacquainted with any military engines fitted to make an impression on the Trojan walls. With such a numerous army, they might have converted the siege into a blockade; but scarcity of supplies compelled the greater part of them to quit the camp. The resource of ravaging the adjacent country soon exhausted itself. Many betook themselves to cultivating the rich vales of the Chersonesus, whose industrious inhabitants had recently been expelled, or destroyed, by the fierce incursions of the barbarous Thracians. Others had recourse to piracy, feized the neighbouring seas, ravaged the unprotected coasts of the Hellespont and Ægean, and plundered or demolished such unfortified places as acknowledged the dominion, or affIlled the arms of Troy. These ravages excited the rage of the Æolians, and rendered them more hearty in the cause of their confederates. In this manner nine summers and winters elapsed, without affording the nearer prospect of a decision to the contest; but, in the tenth year of the war, the seeming misfortunes of the Greeks precipitated the downfall of the proud city of Priam. A dreadful pestilence invaded the camp of the besiegers, and long continued to rage with unabating fury. This calamity was followed by the well-known quarrel between Agenammon and Achilles, which deprived the Greek army of its principal strength and ornament. The Trojans derived new spirits from the misfortunes of their enemies; they ventured to abandon the protection of their walls, boldly affIned the Greek camp, and rilked several engagements, in most of which they were victorious. In the left of these, the beloved friend of Achilles was slain by the arm of Hector, the bravest and most generous of the Trojan race. This event, which was infinitely more dreadful than death to the affectionate ardour of the Greek chief, stirred his hitherto inexcusable renfentment against the proud tyranny of Agamemnon. His return to the camp restored the declining fortune of the Greeks; and the indignant fury of his rage was quenched in the detested blood of Hector, whose patriotic value had long been the firmst bulwark of his father's kingdom. The destruction of Troy soon followed the death of her darling hero. The city, whether taken by storm or by surprize, was set on fire in the night; most of the citizens perished by the sword, or were dragged into captivity; and only a miserable remnant escaped through the confused horror of raging flames and expiring kinmen.

The burning of Troy happened eleven hundred and eighty-four years before the Christian era. Neither the city nor territory ever allumed, in any succeeding age, the dignity of independent government. The sea-coast was planted, eighty years after the Trojan war, by new colonies from Greece; and the inland parts submitted to the growing power of the Lydians, whose arms overspread and conquered all the finest provinces of Lesser Asia.

The Greeks had recovered possession of the admired beauty of Helen; they had taken complete vengeance on the family and nation of her unhappy seducer; but the misfortunes which were the natural consequence of the Trojan expedition, left them little reason to boast of their victory. Of five Boeotian commanders, only one remained, and the siege had been proportionally fatal to the leaders of other tribes, as well as to their warlike followers. Thoïs who lived to divide the rich spoils of Troy, were impatient to fell with their newly-acquired treasures, notwithstanding the threatening appearance of the fieses. Many of them perished by shipwreck; the rest were long tossed on unknown seas; and when they expected to find in their native country the end of their calamities, they were exposed to suffer greater calamities there, than any which they had yet endured. The thrones of several of the absent princes had been usurped by violence and ambition; the lands of various communities had been occupied by the invasion of hostile tribes; even the least unfortunate of those adventurers found their domains unceIlated, or their territories laid waste; their families torn by difcord, or their cities shaken by sedition. And thus the most celebrated enterprife of combined Greece tended to plunge that delightful and once happy country into barbarism and misery.

Gillies's Hist. of Anc. Greece, vol. i.

All the Roman writers assure us that Æneas settled in Italy, and there founded the kingdom of Alba. From him the Caefars afforded to derive their pedigree. Livy alone seems to betray some doubt of this particular, inquiring, with a great deal of deference, that he has not sufficient grounds either to admit or reject the common opinion. But, notwithstanding the unanimous content of the Latins, there are not wanting arguments of great weight, which the learned Bochart has carefully collected, to prove the arrival of Æneas in Italy to be a mere fable.

Dr. Gillies having carefully examined the evidence given by Bochart (Epift. num Æneas unquam fuit in Italia), and by Mr. Wood (Essay on the original Genius of Homer), to prove that the descendants of Æneas reigned in Troy, observes, that notwithstanding the learned ingenuity of a profound, and the plausible criticism of an elegant scholar, the matter seems still too doubtful to warrant contradicting the popular opinion. Some few writers, both ancient and modern, have regarded Homer's account of the siege of Troy as a mere fiction, or the refult of a poetical imagination. Thus Dion Chryfollom (Ora?, xi.) attempts to prove that the siege and deftruction of Troy by the Greeks is altogether fabulous, and deftirute of any foundation in truth. But his performance has been generally regarded as a mere jeu d'esprit, since the author elsewhere (sir. Æneas, p. 225.) disproves what he endeavours to establish in the place before cited. Indeed the siege and capture of Troy are transactions so well attested, and form so remarkable an epocha in hislory, that they cannot be juftly questioned. Nevertheless the learned Bryant, not long ago, published two pamphlets with a view of refuting the generally received opinions respecting the existence of Ancient Troy, and the authenticity of the leading facts in the history of the Trojan war: but his arguments and conclusions have been examined, and, in our opinion, satisfactorily refuted, by Mr. G. Wakefield, in his "Letters to Jacob Bryant, Esq. concerning his Differtation on the War of Troy," and J. B. S. Morritt, Esq. in his "Vindication of Homer, and of the ancient Poets and Historians, who have recorded the Siege and Fall of Troy," as well as the testimony of Le Chevalier, and other modern travellers. See Olivier's Travels in the Ottoman Empire, &c.

TROY, Epoch of the Destruction of. See Epocha.

TROY, Francis de, in Biography, was born at Toulouse in 1645. He was the fon of Nicholas de Troy, a painter of little celebrity, from whom he received the first rudiments of design; but he was sent to Paris when young, where he studied historical painting under Nicholas Loir, and became a member of the Academy in 1674. He afterwards attached himself to the more lucrative profession of portrait painting, and became celebrated in that line. He was sent by Louis XIV. to the court of Munich, to paint the portrait of Maria-Christiana of Bavaria, afterwards dauphine of France. His own portrait is placed in the gallery of Florence. Among the historical pictures which he produced, one of the most renowned was painted for the church of St. Genevieve, in which the magnificence of Paris were represented invoking that saint. He died at Paris in 1730.
Troy, John, was the son of Francis, and born at Paris in 1676. After receiving the instruction of his father in the art of painting until he had made considerable progress, he travelled to Italy, where he studied some years, and soon after his return to Paris he was made a member of the Academy. He was employed by Louis XIV., for whom he painted a series of cartoons for tapestry, representing the history of Either, and several large allegorical subjects for the Hotel de Ville. The king appointed him director of the French Academy at Rome, where he reduced great part of his life; and he acquired so much reputation that his business filled his time in a most respectable manner. His majesty conferred upon him the order of St. Michael, and honoured him with other marks of his particular esteem. He was not less distinguished as a painter of portraits than of history. He died in 1752, aged 76.

Troy, in Geography, a post-township, the capital of Renfrew county, on the E. bank of the Hudson, six miles above Albany; bounded N. by Lansburgh, E. by Brunswick, S. by Greenwich, W. by the Hudson, or the county of Albany. The flourishing village of Troy is in this township, from which it has its name. Along the river are extensive flats, and the river-hill is moity arable. In the S. where the hills approach nearest the river, are some fine streams for mills, and falls of a great height. There are few places on the Hudson, of the fame area, that combine more advantages for a populous town. The soil is good, and here are excellent facilities for water-works; and near the head of flow-navigation on one of the belt rivers in America. In 1810, the whole population was 3895, including 89 slaves, and the number of electors was 334.

The village of Troy is agreeably situated on a gravelly plain, on the E. bank of the Hudson, six miles N. of Albany; it is regularly laid out in streets and squares, and contains 660 houses and stores, five places of worship, two banks, the court-house and prison for the county, a market-house, and many other buildings. Many of the houses, though built of wood, are large and elegant, and those of brick form a considerable number of the whole. The streets are wide, with sufficient side-walks, but unpaved. River-street, the principal avenue, extends about a mile along the river, and receives all the other streets that run N. and S. as well as E. and W. in right lines, forming the rear space into perfect squares, and the straight streets are sixty feet wide. The manufactures are considerable, and trade is extensive, as it employs a great number of floors, &c. on the Hudson. In wealth and trade Troy takes the third rank in the state, among its populous towns. The places of worship belong to the Presbyterians, Baptists, Episcopalians, Quakers, and Methodists; and here are several school-houses, as well as two banks, with an aggregate capital of 870,000 dollars. The River-hill, that rises in the rear of Troy, is very appropriately called mount Ida, and its fine fides and summits present elegant circuits for building that command an extensive view of Troy and the surrounding country. Troy was incorporated in 1801, and is governed by a president and several trustees.

Troy, a town of Massachusetts, in the county of Bristol, containing 1296 inhabitants. — Also, a town of Vermont, in the county of Orleans, containing 231 inhabitants. — Also, a town of the county of Athens, in the district of Ohio, containing 578 inhabitants. — Also, a township of Trumbull county, in the district of Ohio, containing 239 inhabitants.

Troy, White, White of Orleans, or Spanisb White, is a name given to a preparation of chalk, which is finely powdered, formed into cakes, and used in the arts. This chalk is found in great abundance at a village called Villedoup, about four leagues from Troyes in France. It is dug out of the earth in small lumps, and after having been exposed to the air, is bruised and reduced into a gross powder, which is padded through a sieve: when it is perfectly dry, it is diluted with soft water, and formed into a kind of pâte, which, being well tempered, is ground very fine in a mill, and used by painters, gliders, &c.: the qualities that particularly recommend this chalk are that it is being very white, friable, and free from all mixture of adventitious earth and stone.

The white of Orleans is prepared at Caverneau, a small village about nine leagues from Orleans, and reckoned inferior in value to the former. Mem. Acad. Sc. 1754. Ephemeris. Troyennes, an. 1759.

The artificial Troy white, called also Spanish white, is chalk neutralized by the addition of water in which alum is dissolved, and afterwards washed over. It is used by some in water-colours as a white, and may be thus prepared: Take a pound of chalk, and soak it well in water; then wash over all the fine part; and having poured off the first water, add another quantity, in which two ounces of alum are dissolved. Let them stand for a day or two, stirring the chalk once in six or eight hours; wash the chalk again over, till it be rendered perfectly fine, and pour off as much of the water as can be separated from the chalk by that means, taking off the remainder of the dissolved alum, by several renewed quantities of fresh water. After the last water is poured off, put the chalk into a callender-fibre, with a linen cloth over the paper; and, when the moisture has been sufficiently drained off from it, lay it out in lumps to dry on a proper board. Hand. to the Arts, vol. i. p. 177.

Troy Weight, anciently called Trone Weight. See Weight.

Troy Pound. See Weight.

Troyes, in Geography, a city of France, and capital of the department of the Aube, on the Seine; before the revolution the capital of Champagne, and the fee of a bishop. It contained fourteen churches, four abbeys, ten convents, a college, and an hospital. The inhabitants carry on a considerable trade in linen, flax, hemp, cotton, fustians, &c. The environs produce grain, legumes, and fruit in abundance; 18 polls N.W. of Dijon. N. lat. 48° 18'. E. long. 4° 10'.

Trschitz, a town of Moravia, in the circle of Olmutz; 10 miles S.S.E. of Olmutz.

Trsebon. See Wittgenau.

Trsemeschino, a town of the duchy of Warsaw; 10 miles S.E. of Gniezn.

Truce, Trusca, a fufpension of arms; or a cessation of hostilities between two parties at war, which does not terminate it, but merely suspends its operations.

The word, according to Menage, &c. comes from the Latin trucis, which signifies the same; and which Caenere derives further, from the German truc, or trus, which signifies truth.

A truce is either particular or universal: by the former, hostilities cease in particular places, as between a town and a besieging army; by the latter, they are to cease generally, and in all places between the belligerent powers. Particular truces may also admit of a distinction with regard to the acts of hostility, or to the persons; that is, it may be agreed to abate for a time certain hostilities, or two armies may conclude a truce, or suspension of arms, without respect to place. A general truce made for many years, differs from a peace in little else than in leaving the original question of the war undecided, as they found it.

Accordingly
Accordingly, truces are frequently concluded between princes, in order to come to a peace; and truces of many years' date in lieu of treaties of peace between princes, whose differences cannot be finally adjudged.

All truces and suspension of arms are concluded by the authority of the sovereign, who consents to some of them in his own immediate person, and to others through the ministry of his generals and officers. The truce binds the contracting parties from the moment of its being concluded; but cannot have the force of a law with regard to subjects on both sides, till it has been solemnly proclaimed. A ship being on the open seas at the time of publishing the truce, meets with a ship of the enemy, and sinks her; as in this case there is no guilt, she is not liable to pay any damage. If she has made a capture of the vessel, all the obligation she lies under is to restore it, as not retainable by the truce.

If one of the contracting parties, or any person by his order, or with his consent only, commit any act contrary to the truce, it is an injury to the other contracting party; the truce is dissolved, and the party offended is entitled to take up arms, not only to repel the operations of the war, but also for revenging the recent injury offered it.

Sometimes a penalty on the infractor of the truce is reciprocally stipulated, and then the truce is not immediately broken on the first infractor: if the party offending submits to the penalty, and repairs the damage, the truce subsists, and the party offended has nothing farther to claim. If an alternative has been settled, that in case of an infractor the delinquent shall suffer a certain penalty, or the truce be broken, the party injured may choose whether he will demand the penalty, or make use of his right to take up arms again.

The time of the truce should be well specified in order to prevent any doubt or dispute from the moment of its beginning to its period. If no term has been specified for the commencement of the truce, as it binds the contracting parties immediately upon its conclusion, it concerns them to cause it to be published immediately, in order to the observance of it; for it becomes binding on the subjects only from the time of its proper publication; and it begins to take effect only from the moment of the first publication, unless the agreement be other wise. The rules that concern a truce during its continuance are such as follow: Each party may do, within its own territories, what it has a right of doing in time of full peace: advantage is not to be taken of doing what could not be done during the hostilities, e. g. continuing the works of a siege, or repairing breaches, and introducing succours. Nothing is to be undertaken in confined places while the truce continues, but every thing is to be left as it was; e. g. if the enemy does not relinquish a port, town, or village, the truce forbids an invasion of it: subjects inclined to revolt against their prince are not to be entertained, much less invited to treason: persons or effects of enemies are not to be seized during the truce. Intercourse may be allowed during a truce. At the expiration of the truce the war is renewed without any fresh declaration. See Vattel's Law of Nations, book iii. ch. 16.

**Truce of God**. Trêve Drei, is a phrase famous in the histories of the eleventh century, when the disorders and licences of private wars between particular lords and families obliged the bishops of France to forbid such violences within certain times, under canonical pain.

Those intervals they called trêve Drei, trèce de Dieu, q. d. truce of God, a phrase frequent in the councils since that time. The first regulation of this kind, was in a synod held in the diocese of Elno in Rouffillon, anno 1072, where it was enacted, that, throughout that country, no person should attack his enemy from the hour of none on Saturday, to that of prime on Monday, that Sunday might have its proper honour; that nobody should attack, at any time, a religious priest walking unarmed, nor any person going to church, or returning from the fame, or walking with women; that nobody should attack a church, or any house within thirty paces around it. The whole under penalty of excommunication, which, at the end of three months, was converted into an anathema.

These quarrels had prevailed even in the time of Charlemagne, and much more after his death; so that the church found it necessary to interpose. The most early of these interpositions, now extant, is towards the end of the tenth century.

In 990, several bishops assembled in the south of France, and published regulations to restrain the violence and frequency of private wars, ordaining that the transgressor should be excluded from all Christian privileges during his life, and be denied Christian burial after his death. To the same purpose a council was held at Limoges, A.D. 994; and several other councils lifted their decrees for restraining the evil. But the authority of councils was insufficient; and, therefore, a bishop of Aquitaine, A.D. 1052, pretended that an angel from heaven had appeared to him with a writing, enjoining men to cease from their hostilities, and be reconciled to one another. Accordingly, a general cessation took place, and lasted for seven years; and a resolution was formed, that no man should attack or molest his adversaries from the evening of Thursday in each week, to the morning of Monday in the week ensuing, the intervening days being peculiarly holy; our Saviour's passion having happened on one of them, and his resurrection on another. This sudden change was considered as miraculous, and the refpite from hostilities subsequent to it was called the truce of God.

This from being a regulation in one kingdom became a general law in Christendom, and was confirmed by the authority of the pope, and the violators were subjected to the penalty of excommunication. The council of Tours in Rouffillon, A.D. 1041, issued an act, containing all the stipulations required by the truce of God. The nobles, however, disregarding the truce, pursued their quarrels without interruption. Toward the end of the twelfth century, a new revelation was pretended, and, in consequence of it, an association formed under the title of the "Brotherhood of God." At length Philip Augustus, or St. Louis, published an ordinance, A.D. 1243, prohibiting any person to commence hostilities until forty days after the offence which caused the quarrel, and the transgressor was to be tried and punished by the judge as a traitor. This was called the royal truce, and the regulation was productive of good effects. This was farther enforced by an ordinance of Philip the Fair, A.D. 1296. See Robertson's Hill of Charles V. vol. i. p. 335, &c. 8vo.

**Truce, Reckoning of.** See Passport.

**Truce, Conservator of.** See CONSERVATOR.

**TRUCHMAN, DIAGRAMON, or Drogon, in the countries of the Levant, an interpreter.**

**TRUCHMENIANS, or ancient Turkomans, called by the Russians Terekmenian Tartars, are those tribes who parent flock still nomadizes on the eastern coasts of the Caffian, where their territory extends as far as the lake Ariel and Peria. The Truchmenians, in particular, profess on the western side of the Caffian part of the Caffian...**
mountains which stretch from that sea as far as the province of Kakhetty of the Georgian plate. The generality of the districts have their own common princes; others form particular states, and some are under foreign sovereignty. In the former half of the 18th century a part of these hordes fell under the yoke of the Torgotan prince Ayuka, and on that occasion many Tuchmenian families withdrew to the Tartars of Orenburg, Ufa, and Astrakhan. In the year 1770, the remainder of these people, who had not been before under the dominion of the Kalmucks, set themselves at liberty, and at present nomadise as free subjects of the Russian empire about the mouth of the Kuma. Their number is continually increasing by such as escape from the Kirghis, and are found through fling among the Tartars of Orenburg and Ufa, yet to no small amount. See Turken.

TRUCHTERSHEIM, in Geography, a town of France, in the department of the Lower Rhine; 7 miles W. of Strasburg.

TRUCKING, in Commerce. See PERMUTATION, EXCHANGE, and COMMERCE.

TRUCKS, in a Ship, pieces of wood of various shapes, and used for different purposes. Carriage-trucks are cylinders, the breadth or thickness of which is always equal to that of the side-pieces; but the height of the side-pieces and diameter of the trucks must always depend upon the height of the gun-ports above the deck. Flag-strap-trucks are circular flat pieces of elm, with a small sheave at each end. They are fixed by a mortise upon the upper end of flag-strafts, and are used to receive the haliards. Parring-trucks are round balls of elm, or other wood, and have a hole through the middle, in which a rope is reeled, to form the parrels. Steering-trucks are similar to parrell-trucks, but have a score round the middle, to admit a feizing. They are used to lead ropes through. Straddle-trucks are short cylindrical pieces of elm, &c.; they have a hole through the middle, lengthways, a groove down the side the size of the strards, and a score round the middle to admit a feizing. They are seized to the strards to lead ropes through, that they may be more readily found. Lane-trucks are small ornamental pieces of wood like an acorn, &c. and are fixed on the uppermost point of the spindle, above the vane on the mast-head. Their use is to prevent the vane's unhipping.

Trucks, among Gunners, round pieces of wood, in form of wheels, fixed on the axle-trees of carriages, to move the ordnance at sea, and sometimes also at land. See Carriage.

Trucks are also a very large kind of wheel-bawrors, with high wheels moving on planks, used for conveying stuff down a flight declivity in digging canals.

Truck-Bawrows are used in rope-making of different sizes; they have three wheels, and are used to take haws of yarn from the yarn-house, and remnants of yarn, coils of rope, &c. from the ground to the rope-house.

TRUDEAU, in Geography, a town of Pomerania; 9 miles S.E. of Dantizick.

TRUE, something agreeable to the reality of things, or to truth.

In this sense we say, the true God, the true religion, true gold, &c. in opposition to false or pretended ones.

TRUE, in Botany. See HERB PARIS.

TRUE Love of Canada. See HERB PARIS of Canada.

TRUE Place of a Planet, or Star, in Astronomy. See PLACE.

TRUE Altitude, Anomaly, Abnormal, Iteration, Proposition, Discovery, Rite, and Nature. See the several articles.

TRUENTUS, TROENTO or TROONTE, in Ancient Geography, a river of Italy, in the southern part of Picenum, which passed by Aci-lium. At its mouth was a fortified place called "Caletrum Truentinum."

Truffles, formed from truffles, or truffles, of the Latin tuber, or tuberculum, tubera terra, in Natural History, a sort of subterranean vegetable production, or a kind of mushroom, the characters of which are these: they are of a fungous fleety structure, and are of a roundish figure, growing sometimes single, sometimes many together, and always remaining under ground. See Tuber.

Bradley calls them under-ground edible mushroom, or Spanish truffles, and under-ground deer's-balls, or mushrooms.

The ancients, it is evident from their writings, were not acquainted with the fort of truffles which we have in use at present; they describe theirs to have been of a reddish colour, and smooth on the furfurales, as we know not kind very well; it is common in Italy, and is called the wild truffle, and disrevered. They had indeed the white African truffle, sometimes brought to them, and held it in great esteem for its flavour. The Romans called it the Lybian tuber, and the Greeks the Cyrenian myrs.

Avicenna recommends those truffles as the best, which were of a whitish colour within; and this not being a clear white, he expresses himself by a word which signifies sand-coloured, alluding to dusky-white sand, in common use at that time.

It is certain that the first truffles were called by some authors by this epithet arenofa, with a very different meaning, only expressing that they were produced in sandy countries: the European truffles both then were, and now are, mostly produced in dry ground on the sides of falls; but the Lybian were produced only in the burning sands of that country, and these were therefore called sand-truffles.

Serrapio tells us, that the root of all truffles were those produced in sand; and Martial alludes to these, where he describes the fine truffles as breasting the surface of the earth into cracks, and by that means directing people where to search for them. To which purpose Leo Africanus says of the Lybian truffle, that the places where they are may be known by the earth's being raised into hillocks, and breaking into numerous cracks.

The truffle is most abundantly produced in dry fields of a reddish loamy earth, not too poor, according to Pliny, chiefly after rains and thunders in autumn; and they are found to flourish near the roots of elms, the ilex, and some other trees. They do not well bear the severity of hard winters, but are usally scarce all the season after such. The smallest are found about the bigness of a pea, reddish without and whitish within, and they grow from this size sometimes to a pound weight, but such are not common; what are taken up in the spring are distinguihated by their white colour and infirmitity to the taste, and are commonly called white truffles; those taken up in autumn are of a variegated colour within, and are called marble truffles; the inner substance having swelled extremely and changed colour, and the white part now remaining only in form of a number of pipes or tubes, which seem in many places to run to the extremity, and terminate in the chaps and wrinkles of the back. The greyish substance, which is wrapped up among these tubules, when examined by the microscope, appears to be a transparent parenchyma, composed of little bladders or hollow vesicles, in the midst of which may be seen small round bodies, which are unquestionably the seeds of the truffle.

What
What confirms the opinion of their coming from seed is, that there have been truffles discovered in England, and this, at first, only in Northamptonshire, and even only in one place of it, viz. Rufton, a place rock'd with trees formerly brought from Languedoc; and it is only since then, that any truffles have been there observed; whence it is concluded, that the seed of these truffles was brought from France among the roots of the trees brought thence.

These English truffles were first discovered by Dr. Hatton. Dr. Tancred Robinson affirms us, they are the true French truffles, the Italian tartufa, or tartufello, and the Spanih turms de tierra, being not before noted by Mr. Ray as ever known on English ground: indeed he adds, that he has seen them thrive as large at Florence, Rome, &c.

Those observed in England are all included in a studded bark or coat, and the inner substance is of the confistence of the fleshy part of a young chefнут, of a pale-colour, a rank or hircine smell, and unfaavourable.

When the truffles are arrived at such a degree of maturity as to yield feeds, which is generally in August, they are of a fine high flavour and agreeable smell; and the heat and rains at this season greatly promoting their growth, has been the occasion of the old error, that thunder produced them: after this they continue good till the middle of winter, and sometimes even till March: but those gathered from this time till the end of July are small, and only white, never marbled, nor of their high taste.

If the truffles are not taken up when fully ripe, they always rot and burn; whence it is plain, that they are an annual plant, which lives no longer than till they have perished their feeds. And if the place where the old ones have rotted and burnt be examined, the feeds will be found after some time to have vegetated, and a great number of young truffles to be produced in the place: these, if not destroyed by the frosts, are what in the ensuing spring furnish the younger white truffles.

The truffle is very apt to be pierced and eaten within by a worm, and this, though a damage to the particular truffle, is of some service to the people who make it their busines to seek for them: for this worm, after a proper time paied in that stage, changes into a chrysalis state in the body of the truffle; whence he soon after comes out, in the shape of a beautiful white fly; and wherever these flies be found, they are an indication that there are beds of truffles near, as they are never bred in any other root.

These communicate a bitterness to the whole truffle, and make it unfit for the table; though if the whole be carefully searched into, the part eaten by the worm, and the hole by which it made its way in, will be found to be in reality the only bitter parts, and the rest of the truffle, when these are cut out, as good as ever: but, besides these destroyers, the microscope usually discovers on the surface of the truffle a multitude of other devourers, which are small animalcula, continually eating, and searching the cracks of the bark, as the places where the pulp is most easily come at: these somewhat resemble mites.

The earth that produces truffles rarely affords any other plants, these taking up all the nourishment it can afford: the earth all about them smells to very strongly of them, that they are easily found out by it, by the animals which carry their nozes near the ground: and those who sought after them soon found the way of using hogs to search them out; but these being a sort of unmanageable animals, dogs were found which would supply their place with more certainty, and much less trouble. Mem. Acad. Scien. Paris, an. 1711.

By a chemical analysis, truffles are found to abound in a volatile alkali salt, mixed with oil, upon which their smell, &c. depend. They never rise out of the ground, but are found, usually, half a foot beneath the surface of it.

Dr. Hatton has observed several little fibres exuding out of some truffles, and innuminating themselves within the foil, which, in all probability, do the office of roots. The truffles grow tolerably globular, as receiving their nourishment all around them; which they suck in through the pores of their bark or rind.

They are tenderest and best in the spring, though easiest found in autumn: the wet swelling them, and the thunder and lightning disposing them to send forth their scent, so alluring to the fwine: hence some of the ancients called them *cervina*, q. d. thunder-roots.

The ancients were exceedingly divided as to the use of truffles; some affirming them to be wholesome food, and others pernicious: *Aviceina*, particularly, will have them to cause apoplexies. For my own part, says M. Lemery, I am of opinion, they have both good and evil effects: they restoring and strengthening the stomach, promote the femen, &c.; but when used too freely, they attenuate and divide the juices immediately, and, by some volatile and exalted principles, occasion great fermentations, &c. though the pepper and salt, with which they are ordinarily eaten, do doubtless contribute greatly to these effects: their rich taste is owing to their not putting forth any stalk; in effect, their principles being united, and, as it were, concentrated into a little bulb, must yield a richer and more delicious flavour than if the juices were dispersed by vegetation through the several parts of the common plant. Some roast truffles under ashes; and others mix them in sauces.

In Italy, France, England, &c. they eat them as a great dainty, either in fried slices, with oil, salt, and pepper, or boiled thoroughly in their own broth. The hogs are exceedingly fond of them, and are frequently the means of discovering the places where they are; whence the common people call them *favine-bread*. See *Misy* and *Unxon*.

**TRUFFLE-WORMS**, a species of fly-worm which is found in truffles, and lives in and feeds on them, till the time it undergoes the common metamorphoses of these creatures, for the production of a fly, like that from the egg of which it was hatched.

These are very gill, and have two brown spots, easily distinguished near their hinder end, which are the two posterior flignta. They are all over white, and very transparent; and one may very easily distinguish the two black flocks of their two hooks, with which they tear the substance of the truffle, as the other species do their food: when they have arrived at their full growth, which is usually in a few days, then they leave the truffle, and go to seek some proper place, where they may rest during the time of their transformation; they enter the earth for this purpose, and twelve hours after they have gone into it they are transformed into an egg-shaped shell, of a chefnut-brown, of the same fort with that of the blue fleshy-fly.

These are the worms in a manner peculiar to the truffles; but, besides these, they often furnish nourishment to another species, very common in mushroons of the ordinary edible kind, and which has a yellow body, and a black cruflescent head. Reaumur's Hist. Inf. vol. iv. p. 374.

**TRUFTLORN**, in Geography, a town of Bavaria; 13 miles S.S.W. of Vilhohon.

**TRUG**, or Trug-Corn, Truga Fruentes, in our Ab'nant Caleones, denotes a measure of wheat. "Tre trug frumenti vel avenae faciantur duobus, inter praebentium de Hunderton eceleia Herce." MS. de Temp. F. 111.

At Lempiler, the vicar has trug-corn allowed him for x x officiating
efficacious at some capels of eale; as Stoke and Dockley, within that parish.

TRU is also a country word for a milk-tray, or hod to carry mortar in.

TRUHTCHEVSK, in Geography, a town of Ruffia, in the government of Orel, on the Dona; 80 miles W.S.W. of Orel. N. lat. 52° 35'. E. long. 33° 34'.

TRULLIZATION, in the Ancient Architecture, the art of laying on lira or layers of mortar, gypsum, or the like, with the trowel, in the internal vaults, ceilings, &c.

TRUMAU, in Geography, a small island on the eatt side of the gulf of Botnia. N. lat. 63° 54'. E. long. 23°.

TRULLUM, a barbarous word, formed from trulla, etc. and significing done; chiefly used in the phrase, council in trullo.

This was a council assembled, in the year 692, against the Monothelites, in the dome of the palace of Constantinople, called trullo; the name of which it has retained. It was also called the quinquifexum.

The trullo was properly a hall in the palace of the emperors of Constaninople, where they usually consulted of matters of state. This council, held in trullo, was the sixt quinquennial or general council.

TRUMAU, in Geography, a town of Austria; 5 miles E. of Baden.

TRUMBULL, a county of the district of Ohio, bordering on lake Erie, and containing 19 townships and 8671 inhabitants.—Also, a poll-town of Connecticut, in the county of Fairfield, containing 1241 inhabitants; 165 miles N.E. of Philadelphia.

TRUMMAU, a town of Prussia, in Oberland; 16 miles S.E. of Marienwerder.

TRUMAN, a town of Hindooftan, in Marawar; 40 miles S.W. of Tanjore. N. lat. 10° 15'. E. long. 78° 45'.

TRUMPE, in Ichthyology, a name given by none of the English writers to that species of whale, called by the generality of authors ceto, and balena major. This is the phyllifer microops of Linnæus, or blunt-headed cachalot. The Dutch call it the pot-whale fish.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind-kind; used chiefly in war, among the cavalry, to direct them in the service. Each troop of cavalry has one. The cords of the trumpet are of crimson, mixed with the colours of the facings of the regiment.

The word is formed from the French trompette. Menage derives it from the Greek τρομπή, turo, a shell anciently used for a trumpet. Du-Cange derives it from the corrupt Latin trumpa, or the Italian tromba, or trometta; others from the Celtic trumpull, which signifies the same. It is usually made of brass; sometimes of silver, iron, tin, and even wood. Mose, we read, made two of silver, to be used by the priests (Numb. x.), and Solomon made two hundred like those of Mose, as we are informed by Josephus (lib. viii.), which shews abundantly the antiquity of that instrument.

As to the invention of the trumpet, some Greek historians ascribe it to the Tyrrhenians; but others, with greater probability, to the Egyptians, from whom it might have been transmitted to the Israelites. The trumpet was not in use among the Greeks at the time of the Trojan war; though it was in common use in the time of Homer. According to Potter (Arch. Græc. vol. ii. cap. 9.), before the invention of trumpets, the first signals of battle in primitive wars were lighted torches; to these succeeded shafts of flint, which were founded like trumpets. And when the trumpet became common in military use, it may well be imagined to have served at first only as a rough and noisy signal of battle, like that at present in Abyssinia and New Zealand, and perhaps with only one sound. But even when more notes were produced from it, so noisy an instrument must have been an unfit accompaniment for the voice and poetry; so that it is probable the trumpet was the first folk instrument in use among the ancients.

In the 96th Olympiad, before Christ 356, a prize was instituted at the Olympic games for the best performer on the trumpet; and the first performer who gained the prize was Timaeus of Elis; and Herodotus of Megara, a famous trumpeter, who lived about the 120th Olympiad, or 390 years before Christ, was victor at the different games of Greece no less than ten, or, as some say, fifteen several times. There performers on the trumpet appear to have been heralds and public criers, who not only gave the signals at the games for the combatants to engage, and announced their successes, but proclaimed peace and war, and sounded signals of sacrifice and silence, at religious ceremonies. Burney's Hist. of Mus. vol. i. p. 376.

Among the Romans, there were various instruments of the trumpet kind; as the tuba, cornua, bucina, and lituus. The tuba is supposed to have been exactly like our trumpet, widening gradually in a direct line to the orifice; the cornua was bended almost round; and the bucina was somewhat less; the lituus, which was almost straight, but crooked at the extremity, in the form of the auricular flue, whence its name, was a species of clarion, or octave trumpet, made of metal, and extremely loud and thrill, used for horns, as the clarion trumpet was for foot. Horace distinguishes it from the tuba or trumpet. See LITUUS.

The tuba, or long trumpet, called by the Hebrews the trumpet of the jubilees, may be seen in several pieces of ancient sculpture at Rome, particularly on the arch of Titus, on Trajan's pillar, and in a baso-relieve at the Capitol, representing the triumph of Marcus Aurelius.

The modern trumpet consists of a mouth-piece, near an inch broad, though the bottom be only one-third to much. The piece which conveys the wind are called the branches; the two places where it is bent, potencies; and the canal between the second bend and the extremity, the pavilion; the places where the branches take a smaller, or are folded, the knots; which are five in number, and cover the joints.

If an ellipsis (says Dr. Young, Lect. xxxii.) be prolonged without limit, it will become a parabola; hence a parabola is the proper form of the section of a tube, calculated for collecting a found which proceeds from a great distance, into a single point, or for carrying a found nearly in parallel directions to a very distant place. It appears, therefore, that a parabolic conoid is the bell form for a hearing-trumpet, and for a speaking-trumpet; but for both purposes the parabola ought to be much elongated, and to consist of a portion of the conoid remote from the vertex; for it is requisite, in order to avoid confusion, that the sound should enter the ear in directions confined within certain limits; the voice proceeds also from the mouth without any very considerable divergence, so that the parts of the curve behind the focus would in both cases be wholly useless. A trumpet of such a shape does not very materially differ from a part of a cone; and conical instruments are found to answer sufficiently well for practice. It appears, however, unnecessary to suppose, as Mr. Lambert has done, that they differ essentially in principle from parabolic trumpets. It is not yet perfectly decided whether or not a speaking-trumpet has any immediate effect in strengthening the voice, independently of the reflection of sound.
When the found of the trumpet is well managed, it is of a great compass. Indeed its extent is not strictly determinable; since it reaches as high as the strength of the breath can force it. A good breath will carry it beyond four octaves, which is the limit of the usual keys of pianos and organs.

The usual founds of the trumpet are represented by the following musical notes.

```

| B♭   | A♭ |
| E♭   | D♭ |

There is an F♯ in the common trumpet unnoted in this scale.
```

Here the loudest found being denoted by 1, the pitch of the rell, or the number of their respective vibrations, during the time that C vibrates once, will be expressed by the numbers denoting the order of their founds, 2, 3, 4, 5, &c. The founds expressed by the musical numbers, that is, by 2, 3, 5, and their composites, which are 4, 6, 8, 9, 10, 12, 15, 16, are all perfectly in tune; but the founds expressed by numbers not musical, as 7, 11, 13, 14, are false. Three of these, viz. B♭, its octave, and A, distinguished by f placed over them, are too flat; and the remaining note F, marked with an S, is too sharp. See Musical Numbers.

The reason of which is, that B♭ ought to be a tone major below C: that is, its pitch to that of C will be as 8 to 9; but the proportion given by the trumpet is as 7 to 8; which being a less proportion than that of 8 to 9, it follows that B♭ will be too flat. The same holds true of its octave. And A being a tone minor above G, it ought to be to G as 10 to 9: but in the trumpet, it is to G as 13 to 12; which being less than the proportion of 10 to 9, it follows that A will be too flat. On the other hand, F ought to be a femitone major above E; that is, F ought to be to E as 16 to 15; but in the trumpet, F is to E as 11 to 10; which being a greater proportion than that of 16 to 15, it follows that F is too high or too sharp.

This systerm of trumpet-notes is an effectual confusion of those who are for introducing 7, 11, 13, and other primes into music.

In war there are eight principal manners of sounding the trumpet: the first, called the cawlquot; used when an army approaches a city, or paffes through it in a mafch. The second the bout-felle; used when the army is to decamp, or march; at which time the drums beat a general, when the troopers boot, faddle, and get ready. The third is when they found to horfe, when the offfembl begins to beat, on which the troopers mount; and then to the ifandard. The fourth is the charge, in the day of battle. The fifth the watch. The sixth is called the double cawlquot; The seventh the chamade: and the eighth the retreat. Besides these, there are various flourishes, voluntary, &c. used in rejoicings.

There are also people who blow the trumpet so softly, and draw to delineate a sound from it, that it is used not only in church-music, but even in chamber-music: and it is on this account, that, in the Italian and German music, we frequently find parts entitled tromba prima, or 1st, first trumpet; tromba IIa, seconda IIIa, treza, second, third trumpet, &c. as being intended to be played with trumpets.

There are two very great defects in the trumpet, observed by Mr. Roberts, in the Philomphical Transactions for 1692, N° 195. The first is, that it will only perform certain notes within its compas, commonly called trumpet-notes; the second, that though its ordinary compas is from double C♯-flat to C-fa-flat in all, yet there are four notes, the 7th, 11th, 13th, and 14th, in this progression, viz. B♭, F, A♭, and B♭, which are not exact in tune. The same defects are found in the trumpet-marine; and the reason is the same in both. Phil. Trans. Abr. vol. i. p. 607.

Trumpet-Marine, is a musical instrument, consisting of three tables, which form its triangular body. It has a very long neck with one single firing, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the firing is pressed or stopped on the neck by the thumb. Plate XXIV. Miscellany, fig. 4.

It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet, which it does to that perfection, that it is scarcely possible to distinguish the one from the other. And this is what has given it the denomination of trumpet-marine, though, in propriety, it is a kind of monochord. Of the fix divisions marked in the neck of the instrument; the first makes a fifth with the open chord, the second an octave, and so on for the refi, corresponding with the intervals of the military trumpet.

The trumpet-marine has the same defects with the trumpet, viz. that it performs none but trumpet-notes, and none of these either too flat or too sharp. This Mr. Fr. Roberts (ubi supra) accounts for, only premising the common observation of two unison firings; that if one be struck, the other will move: the impulses made on the air by one firing setting another in motion, which lies in a disposition to have its vibrations synchronous to them; to which it may be added, that a firing will move, not only at the striking of an unison, but also of that of an 8th or 12th; there being no contrariety in the motions to hinder each other.

Now in the trumpet-marine you do not flop close, as in other instruments, but touch the firing gently with your thumb, by which there is a mutual concurrence of the upper and lower part of the firing to produce the sound. Hence it is concluded, that the trumpet-marine yields no musical sound, but when the flop makes the upper part of the firing an aliquot part of the remainder, and consequently of the whole; otherwise the vibrations of the parts will flop one another, and make a sound suitable to their motion, altogether confused. Now the aliquot parts, he these, are the very flops which produce the trumpet-notes.

Trumpet, Harmonical, is an instrument which imitates the sound of a trumpet, and which resembles it in every thing, excepting that it is longer, and confids of more branches. It is usually called a sackbut.

Trumpet, Listening or Hearing, is an instrument invented by Joseph Landini, to allude the ear in hearing of persons who speak at a great distance, without the affhance of any speaking-trumpet.

Instruments of this kind, represented in Plate XXIV. Miscellany, figs. 5 and 6. are formed of hollow conical tubes from eight to sixteen inches in length, with a wide mouth from about two to four inches in diameter, and terminating in a small X, X.
TRUMPET.

The principle upon which this instrument is constructed is obvious; for as sound is stronger in proportion to the density of the air, it must follow, that the voice passing through a tube or trumpet, must be greatly augmented by the constant reflection and agitation of the air through the length of the tube, by which it is condensed, and its action on the external air greatly increased at its exit from the tube.

In a speaking-trumpet, the found in one direction is supposed to be increased, not so much by its being prevented to spread all round, as by the reflection from the sides of the trumpet. But as the real action of the instrument, or the true motion of the air through it, is not clearly understood; different persons, according to their particular conceptions of the case, have recommended peculiar shapes for the construction of such trumpets: some having recommended a conical shape, others that which is formed by the rotation of certain curves round their axes; others, again, have recommended an enlargement or two of the cavity in the length of the trumpet, &c. That which has been more commonly recommended as the best figure for such trumpets, is generated by the rotation of a parabola about a line parallel to the axis.

In order to estimate the effect of this instrument, let us suppose A B (Plate XXIV. Mijellang, fig. 7) to be such a length of tube as admits one reflection of the found, emitted by the speaker, from the side B B; let A F be another length, in which the found or voice is reflected five times by the sides, viz. in B, C, D, E, and F: the sound striking the metal tube in B is the same as that at F; but the number of parts forming the periphery of the circle in B is to that in F, as the diameter B B is to the diameter F F; and therefore the intensities with which the parts of the metal will be moved in these peripheries, will be in the inverse ratio of the peripheries, or of the diameters B B, F F. But the parts of the metal move the air contained within the peripheries of the circle, or constituting their respective areas, which are as the squares of the diameters: i.e. the air agitated in B is to that agitated in F, as B B to F F; and consequently, the intensity of the found in the tube of the length A B, is to that in the length A F, as B B to F F, and the inverse ratio of the diameter B to F; or, the intensity in A B is to that in A F :: FF × BB :: BB × FF, i.e. dividing the last ratio by BB × FF :: BB : FF. But the intensity of the found increases the more frequently it is reflected from the sides: let then the number of reflections of the found in B be n, in F it will be 5n, and therefore the whole intensity of the found in B is to that in F as n × BB to 5n × FF. Consequentially, the longer the tube the more numerous will be the reflections, and the greater will be the increase of the found, and the farther it may be heard.

A man, speaking through a tube four feet in length, may be understood at the distance of 500 geometrical paces; with a tube of 15 feet, at the distance of 1800 paces; and with a tube 24 feet long, at a greater distance than 2500 geometrical paces.

The found will be also heightened by having the remoter aperture of the tube wide, more than if it were narrow. However, the effect of the tube in magnifying sound, either for speaking or hearing, depends principally upon its length: nevertheless some advantage may be derived from its particular form and shape.

Some have proposed the figure which is made by the revolution of a parabola about its axis, as the bell; where the mouth-piece is placed in the focus of the parabola, and confe-
consequently the luminous rays will be reflected parallel to the axis of the tube. But Mr. Martin observes, that this parallel reflection is by no means essential to the magnifying of sound; on the contrary, it prevents the infinite number of reflections and reciprocations of sound, in which, according to Sir I. Newton, its augmentation principally consists: the augmentation of the impetus of the pulses of air being proportional to the number of repercussions from the sides of the tube, and therefore to its length, and to such a figure as is most productive of them. Hence he infers, that the parabolic trumpet is the most unfit of any for this purpose.

He observes, that there is one thing more which contributes to the augmentation of the agitations of air in the tube; viz. the proportion which the several portions of air bear to each other when divided by transverse sections, at very small, but equal distances, from one end of the tube to the other.

Thus, let those several divisions be made at the points 

\[ a, b, c, d, e, f, \&c. \]

(see fig. 8.) in which let the right lines 

\[ ak, bk, cm, dn, \&c. \]

be taken in geometrical proportion.

Then will the portions of air contained between \[ B \] and \[ a \], \[ a \] and \[ b \], \[ b \] and \[ c \], \[ c \] and \[ d \], \[ d \] and \[ e \], \[ e \] and \[ f \], \[ f \] and \[ g \], \[ g \] and \[ h \], \[ h \] and \[ i \], \[ i \] and \[ j \], \[ j \] and \[ k \], \[ k \] and \[ l \], \[ l \] and \[ m \], \[ m \] and \[ n \], \[ n \] and \[ o \], \[ o \] and \[ p \], \[ p \] and \[ q \], \[ q \] and \[ r \], \[ r \] and \[ s \], \[ s \] and \[ A \], \[ A \] and \[ B \] form the logarithmic or logarithmic curve: whence Mr. Martin concludes, that a trumpet formed by the revolution of this curve about its axis, will augment the sound in a greater degree than any other figured tube whatever.

Caffeein also is of opinion, that an hyperbola, having the axis of the tube for an asymptote, is the best figure for this instrument. Muc heben. Int. ad Phil. Nat. tom. ii. p. 296. 4to. Martin's Phil. Brit. vol. ii. p. 248, 3d edit.

For other constructions of speaking trumpets by Mr. Conyers, see Phil. Trans. N. 141. for 1678.

TRUMPETS, Feet of, in Ecclesiastical History, one of the membranous feet of the Jews, kept with greater folemnity than the rest, on the first day of the month Tifri. (Numb. xxxix. 1—6. Levit. xxiii. 24, 25.) The day of this fast was the new-year's day of the Jews, in which the people were solemnly called to rejoice in a grateful remembrance of God's benefits to them through the last year, which might be intended by blowing the trumpets, as well as to implore his blessing upon them for the ensuing year, which was partly the intention of the sacrifices offered on this day.

The modern Jews have a notion, which they derive from the Midrash, that on this day God judges all mankind; and therefore, according to Balfnage, they zealot spyred, some a whole month, others four days, and especially the eve of this fast, in confessing their sins, beating their breasts, and homes in laashing their bare backs, by way of penance, in order to procure a favourable judgment on this decive day.

TRUMPET-Fish, Scopasus, in Ichthyology, a fish called also the bellow-fish. In the Linnaean system it is a species of the contrifus; but in the Arthaeon, a species of balistes. Pliny calls it terra. See Centriusus Scolopax.

TRUMPET-Flower, in Botany. See Bignonia and Lonicer.

TRUMPET-Honeysuckle. See Lonicer.

TRUMPET-Shell, or Whelk, Buccinum, in Natural History, the name of a large genus of shells, the characters of which are these: they are univalve shells of the form of a trumpet, according to old pictures, with a wide belly, and a large, broad, and elongated mouth; they have a distinct and regular tail, usually long, though sometimes short; they have a crooked beak, and the clavicle is often elevated, though sometimes depressed and contubulated. In the Linnaean system, the characters of this genus are, that its animal is a flag, the shell univalve, spiral, and gibbous, the aperture oval, ending in a short canal or gutter. Linnaeus enumerates fifty-one species. See Conchology.

The family of the buccina, when examined ever so strictly, is very large; but according to the general custom of authors, of confounding together several genera under the name, it is usually made to appear much larger than it really is. Lifer has made it comprehend a vast number of shells, by confounding it with the families of the murex and purpura.

It is not indeed peculiar to this author, to have confounded these genera: those who went before him have done the same; and Pliny has comprised the buccinum, murex, and purpura, under the general name cleys.

To avoid the general confusion, which arises from not distinguishing the families of the buccinum, murex, purpura, and vis, or screw-shell, it will be proper to observe, that there are regular characters, which distinguish them all, one from another: the characters are these: the buccinum differs from the purpura, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the purpura has a round mouth, and a head somewhat flattened; the tail of the purpura is also usually furrowed, and is shorter than that of the buccinums.

The buccinum differs also from the murex in having a longer tail, by the smoothness and variety of colours of its coat, and by having a larger mouth less furnished with teeth; the murex having a smaller and longer-shaped mouth, its surface covered with points or spires, and several teeth.

It is easier to distinguish the buccinum from the screw-shell, as this is always more long and flender than the buccinum; it has also a flat mouth, and has rarely any tail.

The most singular species of the buccinum clafs, is one that has its mouth turned the contrary way to all other shells: this has been thence called by authors, the unique and the faniform.

The buccina generate in the warm months, and some species of them are seen very frequently remaining in pairs together, upon the rocks defeated by the tide on that occasion. These have been thence suppos'd to be of a different genus, and have been called buccina littoralis; they are usually found in copulation early in the morning. Rumphius de Tel. Aldrovand. de Tel. lib. iii. cap. 251.

The species of the buccina being very numerous, they are arranged under several distinct heads, according to certain obvious distinctions, and as are follow'd: of the buccinum, with long distinct tails and oblong mouths, there are thirteen species; of those with a short tail and a wide mouth, we have twelve species; of those with long erect clinicles, there are
are eleven species; and of those with less erect clavicles, and crooked ricta, there are also eleven species.

It appears from the writings of the ancients, that the famous purple dye, which they obtained from a shell-fish, was not peculiar to any one species; but was found in several of the smaller kinds of bucchina; some of which they called "nurices," from the hollow spines, or long and slender procecles, which run in different directions from their shells.

See PURURA.

M. Reaumur, when on the coasts of Poitou, found certain eggs of fishes arranged in regular order, and in great numbers, on the rocks and falted banks, which had the same property with the purple-dyeing liquor of the bucchina; it is not yet known to what particular fish they belong, or what uses they may hereafter be brought to serve.

Mem. Acad. Par. 1711.

Pliny seems to derive the name bucchina from bucina, a kind of musical instrument; but it is more probable that instrument took its name from the shell to which it bore resemblance, and of which it might probably have been anciently made. Plin. Hift. Nat. lib. ix. cap. 36. Phil. Trans. No. 282. p. 1727.

Bucchina lapidosum is a figured stone, shaped like the former, and probably only a petrifaction of the shell above mentioned.

Ray speaks of a bucchina which was not only petrified, but after petrifaction was converted into a pyrites.

TRUMPETER, in Ornithology, a name given in England to a particular species of pigeon, called by Moore the columba tibicen.

This species is of the middle size of the common pigeon, and made considerably like it; but it is pearly-eyed; it is of a mottled black, is feathered down the legs and feet, and is turn-crowned like the nun, and some of the other species; sometimes like the finnikin, but much larger: this seems to be the beast fort, as being the most melodious. The beast character to know them by, is a tuft of feathers growing at the root of the beak; and the larger this tuft is, the more they are esteemed; the reason of their name is, that they imitate in their cooing the found of the trumpet; but to be often entertained with their melody, it is necessary to feed them frequently with hemp-feed. Moore's Columbarium, p. 45.

Trumpeter is also a name given by Mr. Pennant to the pfophus of Linnæus; because it makes a strong noise with its mouth, which it answers by a different noise from its belly, as if it came from the anus.

Trumpeter, in a Man of War, one whose office is always to attend the captain's command, and be ready at the entertainment of strangers. In the time of an engagement his proper station is on the poop.

TRU, in Geography, a town of France, in the department of the Orne; 7 miles N.N.E. of Argentan.

TRUNCATED LEAF, among Botanists. See LEAF.

TRUNCATED PYRAMID, or CONE, is one whose top or vertex is cut off by a plane parallel to its base. See PYRAMID and CONE.

The word is formed of the Latin truncare, to cut off a part from the whole; whence also truncus, truncare, &c. In Heraldry, they lay truncated.

A truncated cone, or the frustum of that body, is sometimes also called a cutty-cone. See FRUSTUM. See also GAUGING.

TRUNCATED ROOF. See ROOF.

TRUNCHEON, of the French tronçon, and the Latin truncus, a baton; or a kind of short staff used by kings, generals, and great officers, as a mark of their command. See BATTON.

In our military language, it denotes a staff of command borne by a general officer.

TRUNCHEONS, Columns in. See COLUMN.

TRUNDLE, in Rural Economy, a sort of small framed contrivance with two handles at one end, and two low wheels at the other, which is trundled before the person using it. It is found convenient in conveying many forts of weighty matters that are in small parts.

TRUNDLE-Shot, is an iron flint about seventeen inches long, sharpened at both ends, with a round bowl of lead call upon it, about an hand-breadth from each end.

TRUNGIBIN, in Natural History, a name given by Rauwolf, Tournefort, and others, to a sort of manna collected from the allagi maruorum, as the common manna is from the afh; and used in the eastern parts of the world as a purgative. It is what we call the manna Percrum, and though it is itself a very fine and clean kind of manna, yet it is usually to carelessly collected, and mixed with so much filth, that it requires to be given in three times the dose of our in order to purge. The name seems very evidently to be a corruption of terenabin or terenjabin of the Arabsians, which was the word used by all their authors to express the manna Percrum.

TRUNK, a strong cheek or box of a roundish form, at least on the upper side.

TRUNK, in Anatomy, is used for the butto of the human body, exclusive of the head and limbs.

The trunk is divided into three parts: viz. one common, called the spina, and two proper, viz. the thorax or breast, and the pelvis; which see respectively.

TRUNK, TRUNCUS, is also used for the main body of an artery or vein, in contradistinction to the branches and ramifications of it.

The word is particularly applied to certain parts of the aorta and cava.

TRUNK, in Architecture, is used for the fulcrum or shaft of a column. Also for that part of the pedestal between the base and the cornice, otherwise called the dye.

TRUNK, in Gardening and Planting, the common name of the boll, body, or principal stem in all plants of the tree-kind, and of the stalk in thole of all the other forts. It is that part which rises immediately from the root, and is properly the stalk or chief body of the plant or vegetable from the root of which it proceeds, and which ramifies itself into the various boughs, branches, buds, leaves, flowers, and fruit which contribute to it, and are the production of it.

The trunks of most trees, and some other kinds of plants, are of a hard liguorous nature, but in others loft, and in the former are composed of several different original parts, such as an outermost coat or thin layer of hard matter of a fibrous quality, the fibres crossing each other in all directions; and the texture of which in some cafes is so very thin and clear, that the direction or net-work of them can be seen by holding the substance up against the light. The use of this finely woven tunic or coat is that of defending the true bark of the trunk, or the layer which lies immediately below or underneath it, from the action and injurious effects of the atmospheric air; the protecting and keeping open, by its callous nature, the fine pores of the exhaling and inhaling syfemes of vessels; the modifying the various impressions which are made by external objects upon the plant or vegetable; the securing and giving protection to the extreme ramifications of the aerial or aquatic vessels; and the covering of
of the cellular substance, in which the several fluids of it are elaborated and prepared.

A true and somewhat inner bark is situated next to the above in the trunk of the tree, and is of a hard texture, but adhering only loosely in trees to the covering which lies below it. In tender plants this covering is often of a soft pulpy nature, and has the denomination of skin.

A still more inner layer, which is often called liber, forms a third part or covering of the trunk in trees, which is of a membranous and flexible nature, being sometimes altogether separable from the true bark above it, and the white lamina which lies below it. This and the former coat of the trunks in trees are formed of different lamina, as is evident from macerating them in water, by which the cellular substance is destroyed, and the laminated appearance becomes fully displayed. These seem to be parts which are very essential to the life of the plant or vegetable, as in them the chief or principal functions of it are carried on; such, for instance, as those of nutrition, digestion, secretion, and some others. This is plainly proved and shown to be the case, by those trees which have hollow or rotten trunks, the inner being wholly destroyed, and by such plants as keep in vigour by the perfectly good state of their barks, although the internal parts of their trunks or flanks are wholly rotten and destroyed.

The next part, lamina, or coat, which affords a covering or portion to the trunks in trees, is that which has the title of alburnum or sapwood commonly given to it, and which is situated immediately upon the ligneous or woody part, being mostly composed of a rather soft white substance that is fearfully perceptible in some sorts of trees, but which in others is hard and perfectly visible, as in those of the oak, elm, and some others. This coat or part forms an imperfect coat of wood in the trunk, not having yet put on the confidence which is proper for perfect wood, the former of which must be arrived at before the latter can be put on. The hardness and solidity of this part of the trunk are somewhat in proportion to the vigour of growth in the particular tree or plant.

The succeeding ligneous part, is that which is composed of a compact fibrous substance, disposed in concentric layers, and which surrounds the middle or pithy part of the trunks. It seems as if it were constituted or made up of a congeries or collection of dried vacuolar parts; and in plants of the annual and biennial kinds commonly receives the denomination of flesh.

The left, middle, or pithy part of the trunks of trees or plants, is that which is situated in and runs through the hearts of them, and which is of a soft vacuolar nature, differing from that of the cellular textured kind in the perfect whiteness of its colour. It is in the greatest abundance while the trees or plants are in their young state of growth, diminishing in quantity as they mature in age and size, and at length not unfrequently wholly disappearing. Hence it is obviously necessary to them in the beginning of their lives and growths, but not for the continuance of them. It has been suggested as probable, that nature may preserve a superfluous nourishing fluid in this pithy part, if from any cause the young tree or plant should become dry, that then it may be taken up and converted into its food and support.

It must be evident, that what has been said concerning the trunks of trees and plants, must be equally applicable in every respect to the branches and other ramifications, as having the same parts continued from such trunks, of which they in fact form a part in the ways which have already been pointed out.

The trunks of trees and other vegetable productions during their growths are enlarged in their fize and thickness throughout their whole lengths, as well as in their heights, and not at any one particular point or part only, as has been fully proved by numerous and repeated trials of various kinds. And in those which are of an annual or one year's growth and duration, the enlargement or expansion in length continues simply until they have protruded and completed their flowers and flowering proclives, when the constituent parts of the trunks, flanks or flanks begin to take on a hardened form, and at length, in a gradual manner, become quite dry and rigid.

But in those which are of a perennial nature, or of some years growth and duration, this enlargement or increase in the trunks, flanks, or flanks, continues until such times as the leaves decay and fall off in the autumnal season, when a germ or bud protrudes and fixes itself in the place which contains the bafis or rudiment of a new trunk or flanks, that by degrees during the winter months increases in fize until the advance of the vernal season, when, throwing off its former covering, it continues the enlargement or increase of the new trunk or flanks, in the same manner as the inferior or lower part was augmented during the former year; as in the place where the bud is situated, a swelling out takes place and extends itself, which is so continued with the new trunk or flanks, as fearfully to leave any mark or vestige where it was.

The increase of the trunks or flanks in breadth, however, does not proceed from the dilation or enlargement of the woody layers of them, but from the generation and production of new lamina or layers, which are every year deposited and added to them, by the vessels which are contained in the barks of them, as has been sufficiently shown by different experiments.

It has been further shown by observation and experience, that the trunks or flanks of trees and some other plants are augmented every year by two woody lamina or layers, but that the fize or thickness of them is by no means each year exactly the same, this depending in some measure upon the vigour of growth, age, and state of the climate, as they are the greatest when the state of growth is the moist, the age in the middle degree, and the heat of the situation moderate; for the warmer the summer, the more flender the bark, or outward covering.

The trunks, or flanks, and flanks, are of trees and plants, are of several different kinds, and distinguished by many different names. Some trees have trunks or flanks which are very short and thick, others have long large clean ones; and some again have them short, small, and clean, others more knotty; some are very crooked, others quite straignt; and there are still many further differences in these and several other respects. Trees of the oak, elm, beech, and cherry kinds, and the boys, the fire, the tribe, have, in general, the largest, thickest, and clearest trunks or bolls; but there are many other varieties of trees which furnish good useful trunks and flanks, such as the lime, the walnut, the willow, the poplar, the chefum, &c. in particular situations. The trunks of trees are valuable as timber, according to the particular uses and purposes for which they are designed, and to which they are put. Thus in ship-building, their being properly crooked is a great recommendation; while in many works of carpentry and other depositions, their being perfectly straight renders them of the moit estimation. In fact, having a straight clear growth is in general a favourable property, and a circumstance which makes them readily disposed of in the markets.

In plants of other kinds the trunks are often small, so as more properly to deserve the title of flanks; and at other times
times they are of a soft and pulpy nature, so as to demand
the name of ifalka. See Plunt, Stalk, and Stem.

In thefe forts of plants the flalk is the mofi common fort
of trunk or ifem, both among small plants of the tree kind,
and thofe of the nature of herbs, as producing and supporting
the leaves, flowers, and fruit. The name of culm is given
to trunks or ifalks of the straw or haulm kind, which are
peculiar to grasses and grain, and equally bear the leaves,
flowers, and produce or fruit. Frond is a term which is
constantly applied to the trunks or ifems of plants of the
palm and fern kinds or tribes, which are of a compound na-
ture, as being formed of a branch and leaf united or blended
together, and not unfrequently the flower and fruit too.
The peduncle is a term signifying that fort of trunk or
flowering-flalk which rifes fometimes from the root, but
more commonly from the branches, rafing or elevating
the flowers and fruit, but not the leaves. The petiole is a term
implying that fort of trunk or leaf-flalk which bears the
leaves only, and not the flowers.

The term flage is a name which is applied to herbaceous
naked ifems or trunks which ferve to elevate and rafe up
the frutification only, as in those of the hycinth and daf-
fodil kinds.

The term flipes is applied to that fort of trunk or ifem
which is found in fome kinds of flufhy plants, such as
thofe of the common muftroom, and others of the fungus
tribe. See thofe terms refeptively.

Trunk is therefore a term which has a very extenfive ap-
plication in the cultivation of garden vegetables of theculinary
and flowerory ornamental kinds, as well as in planting, to
trees of the timber and other forts, as is more fully fhewn
and explained in fpeaking of flalk, flem, timber, and trees.
See thofe heads.

Trunk, in Canals, denotes a wooden culvert fometimes
made under canals.

Trunk and Valve, is a trunk of wood laid through the
bottom of the bank of a canal, by which water can be let
out of the canal, by drawing of the valve at its inner end.

Trunk, in Mining, is a flreek or flrakes (q. d. ftream)
with a very small ftream or dribble of water, to wash the
flime of tin or copper ore, by which the lighter earthly parts
are carried off with the water. The operation is called
trunking the flrakes.

Trunk is also popularly used for the fnout of an ele-
phant, by naturalists called the probosces.

Trunk, in Natural History, a pointed, hollow, flemder,
and oblong body; joined to the fore-part of the heads
of many insects, and ferving them for fucking the blood
or juices of the animals, or vegetables, on which they feed.

The trunks of flies ferve for dilufing fhining many genera
of thofe little animals, from their different form and other
accidents. Some of these are a tube formed all of one
fimple piece, and others composed of feveral shorter pieces,
nicely joined together: fome are thin and as it were flufhy,
others thick and flemhy; thofe of fome flies are terminated
by a fort of broad foot, or by a fort of thick lips; and
thofe of others have no lips, or at leaft no fenible ones;
and others are made in form of a fpindle hollowed at the
end.

It is often neceffary to have recourse to the microscope,
to dilufing with nicey and exaftnefs between thofe.

Without the affifance of glaffes, however, it is easy to
dilufing among the flies of different genera, three dif-
ferent manners of carrying this organ when in a state of
inaction. Many flies have trunks which they can shorten,
when they are not using them; thofe are fixed in the fore-
part of the creature's head, where there is a cavity deified
receive them when they are not in use. In many species,
this cavity is no more than a mere finus, or hole, in the
fore-part of the head; but in others it is more nicely con-
trived, the anterior part of the head lengthening itself,
and forming a kind of arched vault for its reception.
Other flies have trunks which in the time of inaction are turned,
or fomewhat folded from above downwards: the trunks of
bees are of this kind.

There are others alfo, which have their trunks contained
entirely in a fort of cafe, where they lie ftraight at length,
without being either turned or folded; but they are able to
incline them in any direction, in regard to the position of
their legs: of this kind are the trunks of the cicade,
gnats, &c.

Among the butterfly flafs, a great number are furnifhed
with a trunk; but there are also a great number that have
it not: the fly of the flilk-worm, and many, as well larger
as smaller kinds, are without this organ. Thofe species
which have it, flew it to the firft view; it is placed in the
middle of the head, directly between the two eyes. And
though in feveral fpecies it is very long, yet it takes up
even in thefe but very little room; when it is not in use, it
is always rolled up in a spiral form, in the manner of the
spring of a watch; and even the shortest of them are thus
turned as well as the longeft.

There are among the butterflies, fome which never fettle
upon any thing, but are eternally upon the wing, in the
manner of swallows: thofe feed on the wing as thofe birds
do. We often fee them buzzing about a flower in the
manner of a bee, and in that cafe they fufain themselves
in the air with their wings, while they unroll their trunk, and
thift their extremity into the flower, to fuck from its bottom
the honef-dew, which is the common food of them, of
the bees, and of many other insects. It has been much dif-
puted, among the curious obervers of nature, whether the
trunk be originally composed of two parts, or two trunks
laid clofe to another; or whether it were owing to its flemder
ftructure, that it was eafily fplit by breaking its parts.

Mr. Bonani was of the firft opinion, and Mr. Riget
agreed with him at firft, but he afterwards became of the
contrary opinion, and thought that they really broke in
this fplitting, being originally only one; but Reaumur has
determined the quefion in favour of Bonani: having by
repeated obervations, found them composed of two para-
lel trunks, nicely and evenly laid fide by fide together.

The action of the trunk in fucking is eafily seen on
a giving a piece of fugar to a butterfly that has been kept
without food for fome days, after its being produced out
of the chryfalis; many of the fpecies will in this cafe feed
on the fugar in the fame manner that they would on the
juices of flowers, and will fwoe that the ufe of their
rolling up their trunk at times, is the swallowing what they
have received into it. The trunks of the feveral fpecies of
butterflies are as different in colour as in shape: fome are
black, others reddish, many of a cheafnut colour; fome are
also of a pale brown, and fome of a beautiful yellow; many
of them alfo are hairy on the under fide, and many are
smooth. The thicker trunks are always shorter than the
flat ones, and have only one canal. Reaumur, Hist. Inf.
vol. i. p. 287. 293. 309.

Trunk of Gnats, the iftrument by means of which the
gnat flrikes the flem, and fucks the blood from animal
bodies.

This is a machine well worth an attentive obervation.
As fine and mall as thofe inftrument appears, it is neverthe-
less of a very complex stricture. The piercer, or more pro-
perly
The several species of gnats have great variety in their trunks; and in the observing of many kinds, the true structure of that organ in all will be most regularly and easily found. Some have the case of the piercers only one single tube split lengthwise along its upper part; others have this slit made by the juncture of two cafes, which cover closely a great part of its circumference, and others have the two tubes so well adjusted, and nicely fitted to one another, that a good glass cannot discover them from the rest of the trunk, when in a state of rest; but in others this structure is easily discoverable, as the extremity of one of them, when bent fixed, is still to be discovered somewhat separated from the trunk, and adorned with a pencil of short hairs, like those of the antennæ. The male gnats, which have their antennæ feathered, are those which have the plumes at the extremities of these additional pieces of the case of the trunk; and these have not the beards which are found fated over the trunks of the other species of gnats.

In some gnats four darts are thrust out occasionally from the opening side, one of which serves as a thraeth to the other three. The fides of them are extremely sharp, and they are barbed or indented towards the point.

Out of the immense number of gnats that one sees in summer, in wet places, it is easy to determone that very few have any chance, even once in their lives, to suck the blood of larger animals. The rest, however, are far from being doomed to perpetual famine; the herbs of the field afford them a sufficient nourishment; for these, like many other of the insect tribes, are partly carnivorous, partly otherwise, and feed equally on flesh and vegetables. Reaumur, Hiift. Infecf. vol. iv. p. 580, seq. Baker's Misc. 1743. p. 205.

TRUNK, Fire, in a Fire-ship. See Fire-Ship.
TRUNK-Manna. See MANNA.
TRUNK-Roots of a Plant, are little roots which grow out of the trunks of plants.

VOL. XXXVI.

There are of two kinds: 1. Such as vegetable by a direct defeat, the place of their eruption being sometimes all along the trunk, as in mints, &c. and sometimes only in the utmost point, as in some other plants and trees.
2. Such as neither affend nor defend, but shoot forth a right angles to the trunk, which, therefore, though, as to their office, they are true roots, yet, as to their nature, are a medium between a trunk and a root.

TRUNKED, among Herald, is applied to trees cut off at each end, which are said to be trunked or truncated.

TRUNNIONS, or TRUNIONS, of a piece of ordnance, those knobs or bunches of metal in a gun, mortar, or howitzer, which project from the piece, and bear it upon the cheeks of the carriage.

TRUNNION-Ring, is a ring about a cannon, next before the trunnions.

TRUNNION-Plates, are two plates in travelling carriages, mortars, and howitzers, which cover the upper parts of the side-pieces, and go under the trunnions.

TRUNS, in Geography, a town of the Griifons, where the independence of the Grey League was affirm'd, and an alliance concluded between the chiefs and the communities, on the Rhine; 7 miles W. of Halltze.

TRUNTZ, a town of Prufia, in Ermeland; 9 miles N.E. of Elbing.

TRURO, a large market-town and borough in the western division of the hundred of Powder, and county of Cornwal, England; is situated in a vale at the conflux of the two small rivers Kenwyn and St. Allen, 22 miles S.S.W. from Bodmin, 46 miles S. by S. from Launcefton, and 257 miles W.S.W. from London. It is called in ancient records Trevery, Tryereu, and Trurh burg. It was one of the decayed market-towns for the repairs of which an act of parliament was passed in 1549; but it has now become a place of considerable trade. Its central situation with respect to the commerce and chief products of the county, its improved and still improving state, the regularity and handsome appearance of the buildings, with its increasing population, justify its title to pre-emience amongst the towns of Cornwall. Leland says, 'Ther is a cauliffe, a quarter of an acre bot well out of Truro longeing to the erles of Cornvalle, now cleane downe. The fite theref is now used for a shotting and playing place, out of the town of Truro.' This castle is not mentioned in Domes-day book, and was therefore erected after the Conquest. William of Worcester speaks of it as being in ruins in the time of Edward IV. It stood on an eminence on the more weftly side of the two currents; its only remains are a waite area, and an artificial mount or keep, the earth of which is daily decreasing by its being applied to other purposes. From the increas of the buildings since the time of Leland, the fite is now included within the town, which appears to have derived its origin from the castle; but was fo nearly coeval with it, that it is noticed as existing within a century after the Conquest, and as having a charter in the reign of Henry I. The corporation of Truro, as established by a charter of queen Elizabeth, bearing date 1595, consists of a mayor, four aldermen, and twenty capital burgesses. In these twenty-five persons, the right of electing two members to parliament (poftfelled by the borough ever since the reign of Edward L.) is vested; though the number of inhabitants, as ascertained by the population return of the year 1811, is 2482, when the houses were enumerated at 400. The burgesses of Truro have fundry privileges by grant of their ancient lords; and the mayor's jurisdiction extends even over Falmouth. This laft mentioned privilege, which is said to have been granted

Y by
by king John, and is recorded in the herald’s visitation of 1620, was lost in the early part of the last century; it having been then contended by, and decided in favour of, the inhabitants of Falmouth, who now enjoy the jurisdiction of their own port. This town is situated in the three parishes of St. Mary, St. Clement, and Kenwyn. St. Mary’s church is a spacious edifice, of the architecture which prevailed in England about the reign of Henry VIII. It consists of two aisles of equal size, and a smaller one; and has a modern steeple, which does not correspond with the body of the church. In the windows are several fragments of painted glass; and in one of them, on the south side, is the date 1518, the year when the church was erected. Here are seven meeting-houses for the accommodation of dissenters of various denominations. Truro is one of the original coinage towns; and here only, and at Peuzance, with the exception of a few times at Helston for the convenience of the merchants, have the coinages of late years taken place. Most of the tins is coined here, and Truro is exported here and from any port in the county. The blocks lie in heaps about the streets, and are left entirely unguarded, as their great weight renders it difficult to remove them without immediate detection. Here is a coining-hall; and Hals, in his Parochial History, mentions the town possessing one so early as king John’s reign. Here is also a manufactury for converting block-tin into bars and ingots: the weight of the former is from eight ounces to one pound; that of the latter, from sixty to seventy pounds each. The bars are exported to the Mediterranean and Baltic; the ingots are sent to the East Indies. Considerable quantities of copper-ore are exported from this town to Wales. A manufactury for carpets has been recently established, which is carried on with great facility, and forms a material addition to the export trade. The improvements made in Truro of late years have been very considerable, and particularly since the year 1794, when an act of parliament was passed for lighting and paving the town. The principal street was formerly contracted, and disfigured by a row of houses stretching along the middle from the coinage-hall to the market-place. These have been removed, and a spacious opening formed, from which a new street is built, diverging from the other at right angles. A literary society and a county library were established here in the year 1792. A theatre and assembly-room have also been erected in that part of the town called the High-Crofts: and on the 12th of August, 1793, a county hospital building, was opened in Kenwyn parish, under the patronage of the prince of Wales. A free grammar-school was founded at an early period; and there are two exhibitions, of 32l. per annum, at Exeter college, Oxford, for scholars of Truro school, founded by the trustees of the charitable bequests of the Rev. St. John Eliot, who died in 1760. A central school on Dr. Bell’s plan was established in 1812, in which there are 150 boys and 70 girls. An hospital for ten poor housekeepers in St. Mary’s parish was built in 1832, pursuant to the will of Mr. Henry Williams, who endowed it with lands which now produce 120l. per annum. The corporation make widows the exclusive objects of this charity, and allow them a pension of four shillings each per week and clothes. The market at Truro is held by subscription; the claim to it having been certified and allowed in the reign of Edward I. Here are now two market-days, Wednesday and Saturday, both well supplied with butcher’s meat, fish, and other provisions. A corn-market is also held on Wednesday. Four annual fairs are likewise kept for cattle. About a mile from Truro, on the road to Falmouth, at Callanick, is a large smelting-house for tin. It consists of ten reverberatory furnaces, six feet in height, and about twelve feet in length, each. Culm-coal is used as the flux, in the proportion of about one-eighth to the ore, of which nearly 600 cwt. is smelted within six hours, and yields about 350 cwt. of tin.—Beauties of England and Wales, vol. ii. Cornwall; by J. Britton and E. W. Brayley, 1802. Lysons’s Magna Britannia, vol. iii. 1814.

Truro, a town of Nova Scotia; 40 miles N. of Halifax.—Allo, a town of Barnstable county, in the state of Massachusetts, on the E. side of Cape Cod bay, containing 1200 inhabitants. N. lat. 42° 1’. W. long. 70° 2’.

TRUSAM, a river which rises in the Brifgap, passes by Friburg, &c., and joins the Elziz, near Riegel.

TRUSS, a bundle, or a certain quantity of hay, straw, &c.

A truss of hay is to contain fifty-six pounds, or half a hundred weight: thirty-six trusses make a load.

In June, July, and August, a truss of hay must weigh fifty pounds. The truss of straw is likewise to weigh a certain weight, but this is various, in some degree, in different places. In other matters, the trusses differ greatly according to custom or other circumstances.

A truss of forage is as much as a trooper can carry on his horse’s crupper.

TRUSS, or Bunô, among Floris’s, is a term applied to the tuft of flowers which is formed at the top of the main stem or stalk of some plants of that kind, and which, in the auricula and polyanthus fort, consists of a small bunch of flowers, to which the style of pips or blossoms is given, and which are supported by as many little foot-styles, proceeding from out of the top part of the main stem; some of the properties of which are these: the pips or blossoms, which are the flower parts, consist of the disk or outer rim, the eye or inner rim, the tube or pipe, and the thurm, chives, or apices. The pips or blossoms, in these kinds of flowers, should always be rich, and of a lively good colour or colours, as such as may immediately strike and captivate the mind of the beholder with the idea of real beauty; as this is the property which is the foundation of all the others in these sorts of flower-plants: consequently, where the colours of the flowers in them have a faint or dead appearance, or are of an ordinary and inelegant tinge or hue, they are good for nothing, even though the whole of their other properties should be the most excellent.

In all the painted or striped flowers of these sorts, the colours should conflantly be so equally distributed over the rim or disk, as that there may be an equal uniformity amidst the whole variety; in order that, upon the whole, the fight may not be in the least dissimulated or offended with any fort of disproportion, or perceive one side to be of a brighter or darker hue or shade than that of another. The edges of the rims should be round, or at least so near it, that the indentures may bear but a small proportion to the disk; as when these are deep, and the points of the petals stand in somewhat the flat-form, greatly divided, the largeness of the vacancies will affect the fight with an evident deficiency; and the face is still worse in those pips or blossoms which are liable to run out into a greater breadth on one side of the eye than the other; such irregularities and disproportions are very disgusting in these flowers. The eye, which is the iris or little ring that envelopes the tube or pipe, and which ought to be formed in the manner of the disk, either perfectly or nearly round, and of an entire clear colour; and of a snowly or pure white, in all painted or striped flowers; and of either a white, bright yellow, or good straw...
TRUSS.

The farina, mealy, or dultry property should also be fine; as, if coarse, it will be unpleasant to the eye, or in appearance. The eye of the flower should appear entire, though not separate from the disk or rim; that is, it should be blended with or shaded into it in such a manner, as not to occasion any indistinguish between the edges of the one and the other; as, in flowers where these two properties of the eye are imperfect, the lively contrast, or difference between the rim and the eye, which otherwise reciprocally display, and follow each other off to the belt and molt advantage, is, in a great measure, lost and destroyed. The face of the whole pip, rim, and eye, should likewise be so opened as to lie perfectly or very nearly flat; as when it either inclines inward, which is termed cupping, or throws itself backwards, as in particular flowers, such as the martagon lily, the true form, as well as colours are in some degree obscured by being covered and put out of sight. See True and Thrush.

The length of the pedicles which support the pips or blossoms in the trufs, should be proportioned to the number and size of the pips which they fullain; as, if they be very long, and the pips small, there will be unfightly vacancies in the trufs; or if they be short, and the blossoms many and large, they will be too much crowded together, so that neither the colours can be fully viewed, nor the other properties of the pips be displayed. The pedicles should also be sufficiently elastic, firm, and strong, in order that they may not droop by the weight of the pips or blossoms, and fall loose and in a disarranged manner, but fullain the trufs firmly and closely, without either vacancy or crowding. They should, too, be nearly all of the same length, so that the pips may stand together at the same height, and form a regular umbel, or rather corymb, which is the formal perfection of the trufs. The pips should also be nearly of the same size and colour, so as not to be readily distinguished from each other; as otherwise the unity and harmony of the trufs will be destroyed, and though ever so plentifully formed, would appear as if taken from different sorts of these flowers. A plant of these kinds should blow freely, and expand all its pips or blossoms at the same time; as, by this means, the colours in them all will appear equally fresh and lively; whereas in those which do not blow some of the pips until others have puffed their prime, the whole appearance of the trufs falls much short of that beauty which would otherwise be conspicuous.

The flowers of trufs which support the trufs, and which is mollly termed the main stalk, should be elastic, straight, and sufficiently strong for bearing it without drooping. It is also an excellency in it to be erect and lofty, as thereby the trufs, and of coarse the whole flower, will make a more flatly, commanding, and handsome appearance. Such plants of these kinds as have these properties or qualities can hardly fail to please the curious florists; yet as, on the one hand, some plants may be somewhat deficient in several particulars of leafs confederacion, and still be juttly deemed fine and valuable flowers; so, on the other hand, it will be an additional excellence, in such as have all these properties, that they naturally stand long in bloom, and wear their colours without alteration or fading in any way. The trufs or bunch is probably so named by florists, in consequence of its having naturally something of that appearance about it.

Trusses, in the language of Surgery, is a particular sort of bandage, or apparatus, employed in cases of ruptures, (see Hernia,) for the purpose of keeping up the reduced parts, and hindering a fresh protrusion. It must of coarse be adapted to the situation and nature of the rupture. As a truf is of all the inventions of surgery one of the most important, and highly essential to the health of a large portion of the human race, the most advantageous modes of constructing and applying it are objects which it is as much the duty of the surgeon to know something about, as about any other means of curing or alleviating the danger of so serious and common a difrace as a rupture.

A truf which fulfils its intention properly, should comprize the neck of the hernial fac, and the ring or external opening of the hernia, in such a manner, that a protrusion of any of the contents of the abdomen will be prevented with complete security. Hence, it is the indispensible quality of a good truf, first, to make effectual and equal presfure on the parts indicated, without causing pain or inconvenience to the patient; secondly, not easily to fip out of its right situation, in the varying motions and positions of the body.

The different kinds of horiary bandages may be reduced to the two classes of elastic and inelastic. The latter are composed of leather, fultan, dimitry, or similar materials. These cannot be at all depended on, and should, therefore, be entirely banished from surgery. Since (as Mr. Lawrence has remarked) the fize of the abdomen varies according to the different fates of the vifera, and to the motions of its parcites in refpiration, a non-elastic bandage muft vary confantly in its degree of tightnefs, and keep up either too great or too little pressure. The omen tum, or inteftine, easily fips out when the opening is not exactly clofed, and the patient who wearsuch a bandage, muft be in a state of constant infefticity. Those who lead an active life, or are obliged to use laborious exerfions, will be more particularly expofed to risk. If the patient, after experiencing these defects, endeavour to remedy them by drawing the bandage tighter, he may confine the vifera, but he produces other inconveniences. The increafed pressure injures the perifmatic chord, and may affect the tefifice: the integuments become red, painful, and excoriated; and the bandage must be entirely laid aside, until the parts have recovered. Richter has often seen painful tumefiation of the tefifice, hydrocele, and even eiricocele, produced from this caufe, and entirely difiggated by the employment of a proper truf. Traite des Henries, p. 24.

He also saw the pad of a non-elastic bandage exifte in the region of the abdominal ring, a considerable inflammation, which terminated after a few days in suppuration. The hernia never appeared again at the cure of the defects. The inflammation had extended to the neck of the fac, and obliterated that part. Lawrence on Ruptures, edit. ill. p. 69, 70.

Every truf consists of a pad, for comprifing the ring or aperture through which the hernia protrudes, and of another piece, which surrounds the abdomen. To these are sometimes added a thigh-ftrap, which palies under the perineum, and a fcapulary, which is applied over the fhouler. The ufe of the two latter appendages is to keep the pad from flippin up or down, an inconvenience which it is difficult to prevent in certain caufes, unless a fcapulary or thigh-ftrap be worn. In the inelastic trufles, the piece which extends round the body, is a fimple girt or band; but in every elatic trufs, this part is constructed with a spring, which is the most important thing of the whole inftrument.

Elastic trufles, when they are well made, and fit properly, are to be preferred to the inelastic, in regard to security. They yield to the varying motions of the body; and the liable to fip off the part upon which they are intended to

pre;
TRUSS.

Prefer; and, in general, do not require the use of a thigh-strap, which is usually a very disagreeable part of the trufs to a patient.

The valuable properties of this instrument (says Mr. Lawrence) depend entirely on its spring, which keeps the pad constantly pressed against the herniary opening; and gives it a power of reaction, by which an uniform pressure is maintained under varying attitudes. This elasticity can be attained only by the employment of felt. In the first attempts at procuring something better than the non-elastic bandages, iron was used; and the instruments fabricated by Blegey at Paris were constructed of this metal. It is obviously inadequate to accomplish the ends which we have in view, in treating hernia; yet it is only at a comparatively recent period that its defects have been discovered. Arnaud, whose writings contain much valuable information on this subject, recommends for the spring of a trufs a mixture of malleable iron and felt, so that the instrument may be moulded by the hand to any particular shape which the patient may require; and he is followed on this point even by Richter. A trufs which admits of such management, much in effect be expofed more or less to the objections which apply to the non-elastic bandage; and the only material which poaffes the requisite qualities of firmness and elasticity, is well-tempered felt.

The most important part, then, of an elastic trufs, consists of a faft and narrow piece of felt, adapted to the form of the body, and called the spring. This passes round the afected side of the trunk, terminates anteriorly on an expanded plate of iron, to which it is rivetted, placed over the mouth of the fac, and extends behind to various diftances beyond the spine. The posterior surface of the plate is furnish'd with a convex cushion, termed the pad, and adapted in form and fize to the opening which it is designed to clofe. The spring is covered externally with leather, and that it may fit easily on the body, its inner surface is lined with some soft fabric; a spring flap, extending from its posterior end, paffes round the found side of the trunk, and is faftened to a hook on the front of the plate. This ftrap, being perforated by feveral holes, enables the patient to tighten or loofen the trufs at pleafure. Lawrence on Ruptures, p. 71, 72. edit. 3d.

In a note, this gentleman observes, that the spring of the trufs has commonly been a femicircle, with the posterior end refting on the spine. Camper proposed to carry it round to the anterior superior spine of the ilium on the found side; and Scarpa very much approves the plan. Trufles of this form fit with a firmernef which cannot be given to the others by tightening the flrap. They keep up the rupture much better than even a ftronger spring of the other kind. Hare-skin, with the hair outwards, is conlidered the best article for covering the spring, with a view of keeping it from the ill effects of the perifpiration.

When it is neceffary to make ftrong compreffion, as in large old ruptures, and in perfonis who cannot avoid labour and exercife, the elafic spring should be made accordingly thicker and broader. But an object of the firft-rate imporance is to make the spring pref equal upon every point of the body which it touches. This is what demands the earneft attention both of the furgeon and the instrument-maker, especially as the hips of fome individuals are flat and narrow, while fome of other perfonis are broad and promifcent. A thick, flexible, metallic wire, accurately applied round the pelvis, will ferve to take the compreffion and proper shape of the spring, which may afterwards be altered a little, if found neceffary. The wire, however, should be

somewhat longer, on account of the length of the spring being diminished in the construction of it. Callfen difproves of springs which extend quite round to the oppofite hip; but he thinks a certain bend of the spring downward, near the pad, is ufeful in trufles for inguinal ruptures, as, by this means, the part of the instrument which goes round the pelvis can be made to fit more clofely, and is placed at a convenient diftance from the trochanter, fo as to be lefs liable to derangement. The neck of a trufs for a femoral hernia fhould be shorter, and, in general, the instrument requires in this cafe the employment of a thigh-strap to keep the pad from flipping into the bend of the groin.

The pad of a trufs is frequently composed of a piece of cork covered with leather, with the intervention of some wool or horifc-hair. Proposal have been made to use pads which are formed of bladder or elafic gum, filled with air, but we know nothing of the real merits of fuch contrivances, nor should we expect them to anfwer. Callfen gives a general preference to pads which have a flat and not a conical surface, which lift form not only produces lefs equal pressure, but is more liable to flip. The fhape and fize of the pad fhould of course correspond to the figure and dimensions of the ring, or opening, at which the rupture protrudes. In the inguinal hernia, the pad fhould be long and oblique; in the crural, shorter; in the umbilical, round; and in the ventral, for the mofl part, oval. In large old ruptures, the pad fhould be large accordingly; and in fmall recent cafes, it fhould be fmall in proportion. For fat perfonis, the pad fhould be firm and prominent; but for thin perfonis, it fhould be fatter and softer. Nay, it has even been found fometimes neceffary to accommodate the fhape of the pad to the various degrees of convexity or flatnefs of the os pubis.

Trufles are fometimes fabricated with a pad moveable on the spring, instead of being rivetted to it. This may be inclined upwards or downwards, according to the form of the abdomen; and it is retained at the defired point by a spring flitting into the teeth of a rack. In others, the plate contains a fcrew, by which the cushion is pulfed farther inward, or allowed to recede, at pleafure. Although there cannot be a doubt that fome of these inventions poaffes considerable merit, and are in certain infances, fuperiorly ufeful, it muft be confefled that, in general, their utility is not fo much greater than that of common pads, as to make amends for the want of simplicitv and the increafe of expense. We fhould be forry, however, to fay any thing that would unfairly difcourafe all fuch ingenious endeavours to improve fo difficult an instrument to make perfect as a trufs; and we therefore repeat our belief, that there are particular cafes, in which pads, with racks, fcrews, fprings, &c. may be employed with great advantage.

Notwithftanding every care, sometimes even elafic trufles cannot be hindered from flipping away from the part which they are designed to comprefs. Sometimes they flip downwards, which in fat perfonis is generally caufed by the projection of the abdomen. Occasionally, the fault consists in the instrument becoming displaced in the direction upwards, which moftly happens in thin perfonis, and is produced by the flatnefs of the abdomen. In the firft cafe, the displacement is to be prevented by the ufe of an elafic fcapulary; in the fcond, the flipping of the pad upwards is to be prevented by the employment of a thigh-strap.

When a patient is afflicted with a rupture on each fide, the two protrusions may be very well kept up by means of a fingle trufs, made with two pads, which are joined together, at the exact distance of the rings from each other, by
by a piece of flax, applied over the convexity of the symphysis of the pubes, and proportioned in length to the space between the two openings through which the vificera descend. In such cases, however, it is absolutely necessary to have the spring stronger, than if there were only one rupture. The trusses should also be made to put on that side of the body, upon which the hernia, most difficult to retain, is situated. There are some practitioners, who give the preference to the use of two single trusses, joined together in front and behind with suitable fraps.

With respect to the application and use of trusses, the following instructions seem to merit attention.

1. A truss should never be first applied, or changed, except when the patient is in the horizontal posture, and it is known with certainty that all the contents of the rupture are completely reduced.

2. The first applications of a truss should always be made under the superintendence of the surgeon himself; and care should be taken to put on the instrument in such a manner, that the lower third of the pad will compress the neck of the hernial sac against the os pubis, while the upper portion will compress the abdominal ring. The surgeon should also make the patient acquainted with the right manner of applying the truss; the principles on which it keeps up the bowels, and affords a chance of a radical cure; the requisite cautions to be observed, &c. When a patient first begins to wear a truss, he should be particularly careful not to be guilty of any imprudent exertions, and it behoves him to observe most attentively, that the instrument does not slip from its proper situation. It will also be necessary for him to pay attention to the instrument being neither too tight, nor too loose.

3. The patient ought to be provided with at least two trusses, which should be changed every morning in bed. In order to save the truss, especially in fat persons, who perforce a great deal, it is a good plan to lay a soft piece of linen under the pad.

4. An uneasiness about the ring, which always gives rise to a suspicion that a portion of intestine, or omentum, is protruded, makes it proper to take off the truss, carefully examine the parts, and reduce them if they have defected.

5. When the skin is excoriated by the truss, the part may be cured by sprinkling upon it the powder of acetate of lead, fuller's-earth, lapis calaminaris, &c. or bathing the part with the saturnine lotion. It will also be right to protect the excoriated place with a piece of linen put under the truss.

6. When the preffure of the truss excites affections and swellings of the spermatic cord and testicle, either the thigh-frap must be relaxed, or the lower part of the pad made lefs prominent.

7. In children a very tight truss is altogether hurtful, and may be the cause of various curvatures and deformities; but the erroneous opinion, that they ought not to wear a spring truss, we have noticed in another place. See Hernia.

8. Sometimes very old large ruptures cannot be securely kept up by means of a truss, and even when the pad is extremely large, not more access is often experienced. Should they be retained, it may happen that the ill effects of the compression will be felt in the straitened state of the cavity of the abdomen, or in the speedy appearance of another hernial tumour on the opposite side. Ruptures totally irreducible, and various disorders of the testicle and cord, do not admit of the use of a fole truss.

Whoever wears a truss, should be careful to employ it day and night, without interruption, so that there may be no opportunity for the hernia to protrude again. If, under the employment of a truss, the rupture once defcends again, either a strangulation happens from the narrowness of the neck of the fac; or, at all events, the hope of a radical cure, which may have been entertained for months and years, vanishes in a moment. For experience has put it beyond all doubt, that, by the continual unremitted use of a truss, and the steady retention of the contents of the hernia, the neck of the hernial fac, and the ring, may be gradually lessened in diameter, until they are entirely closed, and a radical cure of the rupture effected. This is more frequently observed in young subjects; seldom in adults; and hardly ever in persons of advanced years. But trusses must be worn a long while, nor should the patient venture to lay aside their use till after many cautious attempts; beginning the experiment at first only in the night-time, and not making it in the day, till after a considerable period from the time when he first thinks himself safe. The longer and more attentively a truss is worn, the greater is the hope of a radical cure. Callahan, Syll. Chir. Hod. tom. ii.

Reproductions of various kinds of trusses may be seen in Plate IX. Surgical Plates. Fig. 1. exhibits a common truss. Fig. 2. the spring terminating in front in the expanded plate of metal, often termed the head of the truss. Fig. 3. represents a truss for a double rupture, with two pads affixed to one spring, and furnished with two thigh-fraps, which, in such a case, would be almost indispensable. Fig. 4. exhibits Dr. Hulme's palm truss, so named by its inventor, from its acting continually like the preffure of a hand. Its particularity consists in its springs not being placed in that part of the truss which goes round the body, but in the pad itself; where there are three spiral springs. A full description of this truss may be found in the Transactions of the Medical Society of London; but as the construction of this instrument does not make much provision against the flipping and displacement of the pad, it can afford very little security to the patient, and does not therefore appear to us to be deserving of recommendation. Fig. 5. represents a very good ordinary truss, made by Mr. Whitford, a surgeon's instrument-maker in Smithfield. Fig. 6. exhibits Mr. Salmon's patent truss, with the additional springs, all three of which together are capable of exerting a force equal to nine pounds weight. A is the spring, made so as to exert a positive force on the cushion at each end. At the front and back ends are different holes, to which the plates and cushions may be instantly shifted by the wearer, so as to admit of being correctly accommodated to the parts. B, C, the additional springs detached, either, or both, of which may be added, so as to increase the power of the truss, if requisite. These springs are simply flipped into a loose leather or other cafe. D, the front plate with its cushion. This plate will apply to either of the holes in the spring, and is kept on the ruptured part by the pin, on which it turns in all directions; so that whatever be the shape or inclination of the body, the plate adapts itself to such changes, not being confined in its direction by any power of the spring. The cushions are simple cafes filled with the foist materials. E, the back plate and cushion. F, a frap to be used, if occasion require, to prevent a forcible removal of the cushions.

Fig. 7. represents a friction of the pelvis, round which the truss is to be applied. Mr. Salmon contends, that if the spring only palled round to the point diametrically opposite that from which it commenced, it would not remain stationary, as both extremities would rest on planes inclined to their action. For a full explanation of this figure, however,
ever, we must refer to Mr. Salmon's Mechanical Analyses of Truffles.

Fig. 8. A truss for a navel-rupture, invented by the late Mr. Marrion, of Leeds. It consists of two pieces of thin elastic stuff, which surround the sides of the abdomen, and nearly meet behind. At their anterior extremity they form conjointly an oval ring, to one side of which is fastened a spring of steel, of the form represented. At the end of this spring is placed the pad, or bolster, that presses upon the hernia. By the elasticity of this spring, the hernia is repressed in every position of the body, and is thereby constantly retained within the abdomen. A piece of calico, or jean, is fastened to each side of the oval ring, having a continued loop at its edge, through which a piece of tape is put, that may be tied behind the body.

When there is a great projection of the abdomen below the navel, as is often the case in women who have borne many children, the oval ring (especially if made wide) is thrown into an oblique direction, and then does not give the pad to bear a bearing upon the hernia. To prevent this inconvenience, Mr. Marrion made the lower bow of the ring to project more than the upper one; and instead of the calico skirt surrounding the ring, he used a belt fastened to the lower bow only, as is represented in Mr. A. Cooper's work on hernia, part ii. plate 9, fig. 6.

Afterwards Mr. Marrion usually made his trusses with the lower bow of the ring only; forming this to project so as to suit the pendulous state of the abdomen. To the round end of the spring, which supports the pad, he affixed a strap, in which were contained spiral wires, for the purpose of regulating the degree of pressure upon the hernia. In a flat abdomen he inverted the position of the trusses, directing the bow to be placed above the navel.

Fig. 9. represents a new truss for a navel or ventral rupture, invented by James Egland, truss-maker at Leeds. The truss consists of two semicircular bows of steel; each of which, at its anterior extremity, is fastened by a distinct brafs hinge, placed vertically, to the outer side of an inter-\[\ldots\]mediate plate of block-\[\ldots\] This plate is somewhat concave on its inner side. The concavity is filled with a piece of blanket, which is covered with leather. This lining causes the leather covering to project a little; but in so small a degree, that when the concave side of the plate is applied to the abdomen, the pressure of the bows brings the rim of the plate, in every part of its circumference, into contact with the skin.

The posterior part of each bow, for about an inch and a half from its extremity, is turned backward, so as to form a flat surface, where it rests upon the back of the patient. To the inner side of this flattened part is sewed a soft leather cushion, lined with blanket, to prevent the patient from being hurt by the ends of the bows.

A strap of leather is sewed to the covering of the truss, near the posterior end of one bow; and a buckle is fixed, in like manner, near the end of the opposite bow, but resting upon it. By means of this strap, the patient can keep to the ends of the bows steady, without being hurt by the buckle. See Hey's Practical Observations in Surgery.

Fig. 10. shews a back view of Egland's navel truss, and of Salmon's patent inguinal truss, applied.

Fig. 11. represents a front view of the same instrument applied.

Besides trusses for ruptures, there are also trusses for another purpose, namely, supporting the scrotum in cases of hydrocele, inflamed testicle, farceocele, &c. These last are commonly called bag-trusses, or supfenoey bandages. In fact, they simply consist of a linen bag, for the reception of the scrotum, and of a girdle which goes round the body, and to which the bag-part of the truss is fastened by means of little hooks, so as to afford the requisite degree of support to the scrotum. Many persons who hunt, and are accustomed to take violent horse-exercise, make use of bag-trusses, in order to keep the scrotum from being hurt by contusions against the pummel of the saddle.

Trusses, in a Ship, a machine employed to pull a yard home to its respective mast, and retain it firmly in that position. As the truss is generally used instead of a parrel, it is rarely employed, except in flying top-gallant-fails, which are never furnished with parrels. It is no other than a ring or traveller, which encircles the mast, and has a rope fastened to its after-part, leading downward to the top or decks; by means of which the truss may be straightened or slackened at pleasure. The haliards of the top-gallant-fail being pulled through this ring, and the fall being hoisted up to its utmost extent, it is evident that the yard will be drawn close to the mast, by pulling down the truss close to the upper part of the fall. For, without the truss, the fall and its yard would be blown from the mast, so as to flying about by the action of the wind, and the rocking of the vessel; unless the yard were hoisted close up to the pulley in which the haliards run; which seldom is the case in flying top-gallant-fails, because they are usually much shallower than those which are fixed or flanging. Falconer.

Trusses, short pieces of ornamental carved wood, mostly in small ships fitted under the taffarel, in the same manner as the term-pieces.

Truss-Parrel. See Parrel.

Truss-Pendants. See Pendants.

Truss-Tackles. See Tackle.

TRUSSED, in the Manage. A horse is said to be well-trussed, in French bien gigues, when his thighs are large, and proportioned to the roundness of the croupe. On the contrary, a horse with thin thighs, that bear no proportion to the breadth of the croupe, is said to be ill-trussed.

TRUSSELS, in Rope-Making, have a back with stout pins and four legs braided together. They are used at the upper end of a rope-ground, or put under ropes of a short length, when the strands cannot be put on the flake-heads.

TRUSSING, in Falconry, is a hawk's raising any fowl or prey aloft, soaring up, and then defending with it to the ground.

TRUST. See Cestui que trust.

TRUSTEE, one who has an eflate, or money, put or trussed in his hands for the use of another. See FIDEI commissum.

TRUSTRA. See Tristra.

TRUTH, VERITAS, a term used in opposition to fallacité; and applied to propositions which anwer or accord to the nature and reality of the thing of which it is affirmed or denied.

Thus, when we say, that four is the fourth part of twice eight, that proposition is true, because agreeable to the nature of these numbers.

Truth, according to Mr. Locke, consists in the joining or separating of signs, as the things signified by them do agree or disagree one with another. Now the joining or separating of signs, is what we call making of propositions. Truth, properly, belongs only to propositions, of which there are two sorts, mental and verbal; as there are two sorts of signs commonly made use of, viz. ideas and words.

Mental propositions are those in which the ideas in our understanding are put together, or separated, by the mind perceiving or judging of their agreement or disagreement.
TRUTH

Verbal propositions are words put together or separated, in affirmative or negative sentences. So that proposition confits in joining or separating of signs; and truth confits in putting together or separating those signs, according as the things they stand for agree or disagree.

Truth, therefore, as well as knowledge, may come under the division of verbal or real; that being only verbal truth, where terms are joined according to the agreement or disagreement of the ideas they stand for, without regarding whether our ideas were such as really have, or are capable of having, any existence in nature. But it is then they contain real truth, when these signs are joined as our ideas agree; and when our ideas are such as we know are capable of having an existence in nature: which, in substances, we cannot know, but by knowing that such have existed.

Truth is the marking down in words the agreement or disagreement of ideas, as it is. Falsehood is the marking down in words the agreement or disagreement of ideas, otherwise than it is: and so far as these ideas, thus marked by founds, agree to their archetypes, so far only is the truth real.

The knowledge of this truth confits in knowing what ideas the words stand for, and the perception of the agreement or disagreement of those ideas, according as it is marked by those words.

Besides truth, taken in the strict sense before mentioned, which is also called logical truth, there are other sorts of truths: as,

TRUTH, MORAL, which confits in speaking things according to the persuasion of our own minds, or the conformity of our expressions to our thoughts, called also veracity; and, in a more general sense, comprehending also faithfulness, which is a conformity of our actions to our words. Whereas lying or falsehood, as opposed to truth, is generally a mean, selfish, or malevolent, and always an unfavourable, endeavour to deceive another, by signifying or alluring that to be truth or fact, which is known or believed to be otherwise; and by making promises, without any intention to perform them.

TRUTH, METAPHYSICAL OR TRANSCENDENTAL, which is nothing but the real existence of things conformable to the ideas which we have annexed to their names.

In which sense a clock may be said to be true, when it answers the idea or intention of the person who made it. Others will have metaphysical truth to confit in the agreement of a thing with the idea thereof in the divine understanding.

TRUTINA HERMETIS is used, among Astrologers, for an artificial method of examining and rectifying a nativity, by means of the time of conception.

TRUTINATION, formed from trutina, a pair of scales, the act of weighing or balancing a thing.

TRUPLICATE, in Ichthology, the name of a genus of fish, of the trout kind, which are distinguished from all other fish by a small fat fin, which they all have near the extremity of the back, and which has no rays or nerves. Of the fish of this genus, some live only in fresh waters, never entering the sea or salt rivers; others frequent both the fresh and salt waters, and are therefore called anadromi or catadromi. These leave the fresh waters while young, and go into the salt rivers to feed and grow, and again return into the fresh rivers at the time of their full growth and spawning, that their offspring may have the same advantages themselves have had, of being hatched into life in fresh water.

TRUXILLO, in Geography, a city of South America, in the viceroyalty of Peru, and fee of a bishop. It was built in the year 1555, by Don Francisco Pizarro, in the valley of Chimo. Its site is pleasant, notwithstanding the sandiness of the soil, the general inconvenience of all the towns in the valleys. It is surrounded with a brick wall, and from its circuit may be clasped among cities of the third order. It stands on a small river, about half a league from the sea: two leagues to the northward is the port of "Guanchaco," the channel of its maritime commerce. The houses make a creditable appearance. The generality are of bricks, with flatly balconies, and superb porticoes; but the others are of barnware. Both, however, are low, on account of the frequent earthquakes, and few of them have so much as one story. The corregidor of the whole department resides in this city, and also a bishop, whose diocese begins at Tumbes; with a chapter, consisting of three dignitaries, namely, the dean, archdeacon, and chanter, with four canons, and two prebendaries. Here is an office of revenue, assisted by an accountant and treasurer, one of which resides at Lambayeque, several convents, a college, and an hospital. The inhabitants consist of Spaniards, Indians, and all the other calls. Among the first are several rich and distinguished families. The women in their drets and costumes follow nearly those of Lima. About a league from the city is a river, the waters of which are conveyed by various canals through this delightful country. The diocese comprehends eight jurisdictions, viz. Truxillo, Sama, Pura, Cayamaca, Chachapayas, Ichala and Chillos, Pataz or Caxamarqulla, and Juan de Bracamaros; the last is situated in the audience of Quito; the rest in the viceroyalty of Peru. The jurisdiction of Truxillo is situated on the coast of the Pacific ocean, and extends twenty leagues in length, and as much towards the interior part of the country, compassed throughont of beautiful valleys. In this climate there is a sensible difference between winter and summer; the former being attended with cold, and the latter with excessive heat. The country of this whole valley is extremely fruitful, abounding with figar-canes, maize, fruits, and garden vegetables, as also with vine and olive yards. The parts nearest the mountains produce wheat, barley, and other grain; so that the inhabitants enjoy not only a plenty of all kinds of provisions, but likewise make considerable exports to Panama, especially of wheat and figars. This remarkable fertility has been improved to the great embellishment of the country; so that the city is surrounded by several groves and delightful walks of trees. The gardens also are well cultivated.

The truttaceous fish are divided into two orders, those which have, and those which have no teeth. Of the edentulous kind, or such as have no teeth, are the lavaretus, ferra, thymallus, oxyrinchus, and albula; and of the toothed kind, are the falmo, umbra, trutta, carpio, &c. In connection, the truttaceous fish have all apophyses to the pyrurus, and are all a high-tailed and fine fish for the table. Ray's Ichthology, p. 182.
TRY

cultivated, and make a very beautiful appearance, which, with a continual serene sky, prove not less agreeable to travellers than to the inhabitants. The city is situated 480 miles S. of Quito. S. lat. 8° 6'. W. long. 79° 20'.

The progress of this city to splendour and opulence was very rapid; but in the midst of its career it was attacked and defeated by the buccaneer Francis Grammont, in the year 1678. The consequence of his invasion was a almost a temporary depopulation. However, the fulblury of the air and the fertility of the soil have drawn thither inhabitants sufficient to make their number amount to 7600 persons. The land about it produces sugar, cacao, indigo, coffee, and in general all the productions of the torrid and some of the temperate zones. Wheat is obtained here of an excellent quality, and in abundance. They also breed sheep and goats: their mutton is large and good; their cheese much commended; and of the wool they fabricate goods, of certain and profitable fale. The women are employed in making sweetmeats, which have an extensive circulation. The commercial articles of Truxillo are conveyed to Maracaibo by the lake; but their most common intercourse is with Carora, where they send their goat and sheep-skins to be dressed. The air enjoyed by the inhabitants of Truxillo is pure; but their waters, though clear and light, are impregnated with metallic particles. The spot occupied by the city lies between two mountains, fo as to give it the shape of a coffin. Here is a monastery of Franciscans, and also another of Dominicans. The nuns of Truxillo employ themselves in making delicate articles of bark, which have a ready sale.

TRUXILLO, a sea-port town of Mexico, in the province of Honduras, situated on a hill, near the sea; frequently ravaged by the English and the Dutch, and at present much decayed. N. lat. 15° 45'. W. long. 86° 40'.

TRUXILLO, or Nuestra Senora de la Paz, a town of South America, in the province of Venezuela; 120 miles S. of lake Maracaibo. N. lat. 8° 45'. W. long. 69° 34'.

TRUXTON, a post-township of New York, in the N.E. corner of Cortland county, 424 miles W. of Albany; bounded N. by Fabius, on Onondaga county, E. by Madison county, S. by Solon, and W. by Preble: its extent is 10 miles E. and W., and 5 miles N. and S., comprising the S. half of the township of Fabius, in the military tract. It resembles Fabius in the general character of surface, soil, timber, &c., and is watered only by branches of the Troughingoa that rise in that town. The soil is good, the agriculture productive, and the township improving. In 1810 the population was 11,2, the senatorial electors 129, and the taxable property assessed at 4,673 dollars. The settlements commenced in 1800. Truxton village is agreeably situated, and has about twenty houses.

TRUZZA, or Truizzo, a town of Tunis, with a populous spring. Little of the town exists but ruins; 84 miles S.S.W. of Tunis.

TRY, Try, in Sea Language. See TRYING.

TRYAL. See TRIAL.

TRYBERG, in Geography. See TRIBERG.

TRYBION, a word used by the old medical writers, to express the pot or ditch in which the medicines used in fumigations were placed at the time of use.

TRYCHNUS, in Botany, the name as ftychonus, the name of nightshade.

TRYDEFRIN, in Geography, a township of Pennsylvania, in the county of Chelten, containing 1253 inhabitants.

TRYGGEVELDE, a town of Denmark, in the island of Zealand; 4 miles W. of Store Hedingen.

TRYGUM, in Ichthyology, the Greek name given byelian, Atheneus, and Appian, to the fish which we call the paffinae marina, or fire-faire. Artifole and some others write it trigum.

TRYING, in Pharmacy, the purifying of fat substances by means of melting, and separating them from their membranes, &c. See Suet.

In the College Dispensatory, the method laid down for the purifying of land, fuel, &c. was this: melt them at a gentle fire, with the addition of a little water intermixed, and, when melted, strain them from the membranes. The addition of water in this keeps the fat from burning and becoming black, which it would otherwise do; for the water not being capable of receiving any greater degree of heat than that of boiling, will keep the bottom of the vessel from growing too hot, much better than the nicest management of the fire could do.

TRYING, in Sea Language, denotes the situation in which a ship lies nearly in the trough, or hollow, of the sea, in a tempest, particularly when it blows contrary to her course. In trying, as well as in scudding, the fails are always reduced in proportion to the increase of the storm. Thus, in the former state, the ship may lie by the wind under a whole main-fail, a whole fore-fail, or a whole mizen; or under any of those fails, when diminished by the reef or balance. As the least possible quantity of fail used in scudding is the gooie-wings of the fore-fail, so, in trying, the smalllest portion is generally the mizen-flay-fail, or main-flay-fail; and in either state, if the storm be excessive, she may lie with all the fails furled, or, according to the sea-phrase, under bare poles.

The intent of spreading a fail at this time is to keep the ship more steady, and, by pressing her fide down in the water, to prevent her from rolling violently; and also to turn her bow towards the direction of the wind, so that the f洛克 of the waves may fall more obliquely on her flank than when she lies along the trough of the sea. While she remains in this situation, the helm is fastened close to the lee-fide, or, in the sea language, bord-a-lae, to prevent her, as much as possible, from falling-off. But as the ship is not then kept in equilibrio by the effort of her fails, which at other times counterbalance each other at the head and stern, she is moved by a fluid but continual vibration, which turns her head alternately to windward and leeward, forming an angle of three or four points in the interval. The part where the flops, in approaching the direction of the wind, is called her coming-to, and the contrary excess of the angle to leeward is termed her falling-off. Thus, suppose the wind northerly, and a ship trying with her board-side to windward: if, in turning her head towards the source of the wind, she arrives at N.W. or N. 35° W. and then declines to the leeward as far as W. 45° S. or S. 45° W. the former will be called her coming-to, and the latter her falling-off. In this position she advances very little, according to the line of her length, but is driven considerably to leeward. Falconer.

TRYLISIA, in Geography, a town of Ruffian Poland; 10 miles E.N.E. of Zytoriens.

TRYON, a county of the state of New York.

TRYON MOUNTAINS, mountains of North Carolina, west of Salisbury, bordering on Tennessee.

TRYPETHELIUM, in Botany, from τρύς, a perforation, and ἄνω, a nipple, on account of the mammiliary orifices of the warts containing the receptacles; a genus of the great family of lichenet. (See that article.)—Achar. Lichenogr.
TSA

Eff. 2.6. Crust somewhat cartilaginous, flat, uniform, fixed. Warts of the substance of the crust, coloured, prominent. Receptacles several, concealed in the substance of each wort, of a thick, black, simple texture, the orifice nipple-shaped, projecting as far as the surface of the wort, the globular cellular nucleus being altogether internal.

Professor Acharius defines eight species, all found on the banks of different tropical trees. They are nearly allied to his Theolotrema. See that article.

TRYPHALIA, in Ancient Geography, a maritime country of the Peloponnesus, between Messenia and the Elide, according to Polybius.

TRYPHERA, Τρυφέρα, in Pharmacy, a denomination given to divers medicines, especially of the opiate kind.

The great tryphera is composed of opium, cinnamon, cloves, and several other ingredients; it is used to fortify the stomach, to stop fluxes, and is good for some diseases of the womb.

The word is formed from the Greek τρυφέρα, delicate, on account of their gentle and pleasant operation, or, according to others, because they make those who use them reft.

The Saracen tryphera, and Persian tryphera, thus called, because first introduced, the one by the Saracens, and the other by the Persians, were both of them gentle purgatives.

TRYPHIDORUS, in Biography, a Greek poet, was a native of Egypt, and commonly referred to the reign of the emperor Anattius, in the commencement of the fifth century. Of his history little is known; but he was dennominated a Grammarian, and wrote many works, the titles of which are given by Suidas. Of these, none are extant besides his poem on the destruction of Troy, τάξις Ἀλκιβίδας, in about 700 lines, without any discriminating merit besides its being a relic of Greek literature. It was first printed by Aldus, and has passed through subsequent editions by Merrick, Oxon. 1741; Bandini, Florent. 1759; and Northmore, Oxon. 1791, which are those the most esteemed. Volusius. Moreri. Gen. Biog.

TRYSTS, CATTLE, a term applied to fairs for them in some of the northern parts of the island.

TRYSUNDA, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 9'. E. long. 18° 35'.

TRYVET, a village of Ireland, in the county of Meath. This place was rebuilt by Hugh de Lacy, and peopled by a colony of English; after which it became a consider able town, but is now fallen to decay; 8 miles S.E. of Navan.

TSABA, a town of Asiatic Turkey, in Natolia; 10 miles E. of Bohl.

TSA-CHOUI, a town of Corea; 43 miles S.S.E. of Koang-techeou.

TSAKATHURN. See CUSAKATHURN.

TSAKTELU, a town of Asiatick Turkey, in Caramania; 28 miles N.N.E. of Akchief.

TSALGO, a town of Georgia, in the province of Carduel; 50 miles S.W. of Telif.

TSAL-HASSAR, a town of Arabia, in the province of Asijadr; 45 miles N.W. of Cathem.

TSANG, a city of China, of the second rank, in Peche-li; 102 miles S. of Peking. N. lat. 38° 21'. E. long. 116° 84'.

TSANG-CHEIN, a town of Corea, near the Sea; 35 miles S.S.W. of Han-techeou.

TSANPOU. See Sanpo.

TSANTSE-AGHISHI, a town of Asiatic Turkey, in Natolia; 12 miles N.W. of Eregri.

TSAO, a city of China, of the second rank, in Canton; 72 miles W.S.W. of Yeng-techeou. N. lat. 35° 22'. E. long. 115° 10'.

TSAO-SU, a small island near the coast of China. N. lat. 25° 22'. E. long. 119° 42'.

TSAO-TCHANG, a town of Corea; 20 miles N. of Han-techeou.

TSAPHARI, in the Materia Medica of the Ancients, a name given by some to the cadmia, called by Dioscorides placitis, and by others of the Greek writers, zonitis and onychitis. It was a flat kind, forming a fort of coat or crust on the walls or sides of the furnace; hence it had the name placitis, or crustaceous; and it was called onychitis and zonitis, because, when broken transversely, it appeared made up of several succedaneous plates, which had the appearance of so many belts or zones. Serapion tells us, that this and the botryoida cadmia were dug out of the mines; that is, that they were natural productions; but this is erroneous, and contrary to all the accounts of the ancients.

TSASMA, in Geography, a town of Croatia; 8 miles E. of Ivanitz.

TSATSORKEN, a town of Thibet; 501 miles E.S.E. of Laffa.

TSCHAGATAY, or Dschagatai, a name given to the Mongolian state, which was ascribed to one of the sons of Tschingis-khan, His called after the name of its founder, to whom his father ascribed the Great and Laszchiharkh, Turfan, the country of the figures, and part of the present Kalmuckey.

TSCHA-HAFFER, a town of Arabia Deferta; 80 miles W. of Cathem.

TSCHALMA-CALAB, a town of Persia, in Adiribetzan; 60 miles S.E. of Tauris.

TSCHARSHEBEB, a town of Asiatic Turkey, in Natolia, on the Meinder; 20 miles N. of Degnaizels.

TSCHASCHWITZ, a town of Silezia, in the principality of Neiff; 4 miles W. of Neife.

TSCHASLAW. See Czaslaw.

TSCHAZLOWITZ, a town of Bohemia, in the circle of Konigingratz; 14 miles E.S.E. of Konigingratz.

TSCHAVAT. See Javat.

TSCHEAHDORF, a town of Silezia, in the principality of Neife; 9 miles N.E. of Patchkau.

TSCHEKENAGAR, a town of Asiatic Turkey, in Caramania; 50 miles N.E. of Cogni.

TSCHELATSCH, a town of Austrian Poland, in Galicia; 28 miles N. of Cracow.

TSCHENGA, a town of Bulgaria, near the Daphne; 50 miles W.S.W. of Varna.

TSCHESTOCKOWA, a town of Austrian Poland, in Galicia; 46 miles N.W. of Cracow.

TSCHEREMISSES, or Tschermess, a tribe of Finns, who dwell in the governments of Viatka, Kazan, Simbirsk, and Ufa, on both shores of the Volga, especially the left. They call themselves Mari, i. e. men. Although their language be mixed with Tartarian and Russian words, it is easily distinguishable as a Finnish dialect. The Supreme Being they call Yuma. In the time of the Tartars they were subject to them, and dwelt more fartherly, between the Volga and the Don; but at the downfall of the Tartarian dominion, they fell to the Russian empire, and even in this state they long retained their own khan, which, however, vanished upon the
the extinction of the princely race. They were formerly a pastoral people, but under the Russian government they are gradually become husbandmen. The present amount of them is not known; but they have been estimated at 25,000.

TSCHERIKOV. See Tcherikov.

Tscherekov's island, an island in the North Pacific ocean, so called by Capt. Vancouver, after the companion of Bering. In the point of view in which Capt. Vancouver saw the twelfth, southern, and eastern sides of this island, it appeared to form a somewhat irregular four-sided figure, about ten leagues in circuit; having from its western part, which is low and flat, and which had the appearance of being insular, a remarkable high, flat, square rock, lying in a direction S. 60° W. at a distance of two miles, between which and the island is a ledge of smaller rocks. The centre of the island appeared to be in N. lat. 52° 49'. E. long. 203° 4'.

TSCHERKASK. See Tcherkask.

TSCHERKASSIANS. See Tcherkasses and Circassians.

TSCHERNENBL. See Zernembl.

TSCHERNOYAR. See Tcher kho yar.

TSCHERSK, or Tcherisko. See Czersko.

TSCHESCHENIANS, or Mischenhians, a tribe of vaffals to Russia, living in the eastern part of the great Kabardin, who in time of war can raise 5000 horsemen.

TSCHESME', a small town of Alia Minor, situated almost opposite to the island of Scio, at the head of a spacious road, to which art has no occasion to add, in order to make it a good harbour. A citadel, founded by the Genoese, fortified by which, the republic of Scio, keepng to the sea-shore, and seems intended to secure from all insult both the town and the harbour. Tschefme is built on the ruins of Cyllus. This road is famous for the victory which the Roman fleet gained there over that of Antiochus, and also for the burning and total destruction of the Turkish squadron by the Russians in 1770. Geographers place at the head of a bay, or three leagues to the N. of Tschefme, the ancient Erythra, celebrated for the oracles of the Sibyl. The territory of Tschefme furnishes grain and fruit in abundance: a little oil and a great many raisins are also produced here. It is from this harbour that the island of Scio draws a great part of its subsistence, and by means of it frequently keeps up an intercourse with Smyrna.

TSCHETCHE, the name of a colony of strangers and Christians, who are excluded from the world in a sort neglected part of the wilds of Caucasus, so called in the language of the country. These poor people are said to lead lives of the most exemplary piety, and to exhibit a primeval simplicity of manners. They are totally ignorant of their origin, any far nearer than that they are strangers, and their being considered as such by the scattered neighbouring nations. From an affinity in their language, and some other circumstances, they are supposed to be descended from a colony of Bohemians, who, flying from religious persecution in their own country towards the close of the fifteenth century, found at length a refuge from oppression in the retreat of mankind which these remote deferts afforded.

TSCHIGRI, a town of Russia, in the government of Kurilk; 48 miles E.N.E. of Kurilk.

TSCHILLA, a town of Boemia, in the circle of Rakonitza; 8 miles S.W. of Rakonitza.

TSCHIRNE, a town of Silicia, in the principality of Glogau; 20 miles E. of Gros Glogau.—Alfo, a river of Silicia, which runs into the Borob, two miles below Sagan.

TSCHIRNHAUSEN, Ehrenfried Walter von, in Biography, an ingenious mathematician, was a descendant of a noble Bohemian family, and born at Kifflingwald, in Upper Lusatia, in 1651. Having studied for some time at the university of Leyden, directing his particular attention to mathematics and philosophy, he entered into the Dutch army in 1672, and for the purpose of further improvement visited France, Sicily, Italy, and Malta. He also established three glas-houses in Saxony, with a view to the improvement of the science of optics, and having flewed how porcelain might be made from an earth found in that country, he may be regarded as the founder of the Dresden porcelain manufactory. As to his claims on the invention of cauliic curves, we refer to the article Caufic Curve. His account of them was communicated to the Academy of Sciences at Paris in 1682. See also the fame Memoirs for 1703. For the construction and powers of his burning-glas, constructed about the year 1687, we refer to the article Burning-glafs. Headles of the fame which he so justly acquired, Tschirnhausen took delight in encouraging the researches of others, who were engaged in pursuits similar to his own, and was at considerable expense in printing works of public utility. He died, highly esteemed and much regretted, in the month of September 1708. He furnished the Leipfe Transactions with many articles; and also the Memoirs of the Academy of Sciences with the following: v. "Observations on Burning-glas of three or four feet Diameter," in the vol. for 1699; "Observations on the Glas of a Telescope con- structed in Saxony, and the thirty-second feet focal distance," 1700; "On the Radius of Curvatures, and finding the Tangents, Quadratures, and Rectifications of many Curves," 1701; "On the Tangents of Mechanical Curves," 1702; and "On a Method of Quadratures." The only work published separately was his "Medicina Mentis," referring Malebranche's "Recherche de la Verité," but more extensive; first published in 1687, and again with improvements in 1695. Montucla, Hist. des Mathem. Hutton's Math. Dict.

TSCHIRNHUSIANA Quadratrix. See Quadratrix Tefirhauhiana.

TSCHOPA, in Geography, a river of Saxony, which rises near Wejental, on the borders of Bohemia, and runs into the Mulda, between Dobcin and Leifing.

TSCHOPA, or Zhepopou, a town of Saxony, in the circle of Erzegberg, celebrated for its blue manufacture; 7 miles S.E. of Chemnitz. N. lat. 56° 4'. E. long. 13° 2'.

TSCHUDI, Eundus, in Biography, an eminent Swiss historian, was descended from a noble family, and born at Glarus in 1505. After completing his school education, he went to Basle, and accompanied his preceptor Glareanus to France, with a view to further improvement. Upon his return to his native place, he was employed, in 1528, on a mission respecting the Reformation, in which he conducted himself to the satisfaction of both Reformers and Catholics; and in the following year was chosen chief magistrate of Sargans. By his discharge of the duties of this office, he gained increasing reputation, and more extended truits of a similar kind. His great object was to enlarge his acquaintance with the Helvetic history; nor did he cease to pursue it, even in the military service of France, or in any of the honourable stations which he was appointed to occupy. Towards the close of his life he was severely afflicted with the stone, but death terminated his pains and labours in the year 1572, and 69th year of his age. His principal works were "A Description of the ancient Rhaetia," published at Basle in 1538; the " Helvetic Chronicle," commencing with the
The page contains text in English, discussing various geographical and cultural topics. The text seems to be a part of a larger work, possibly a historical or geographical text, discussing regions, peoples, and features of the world. The text refers to places such as Siberia, Turkey, and several others, and includes discussions on languages, agriculture, and natural phenomena. The text is too complex to transcribe accurately without context and is likely part of a larger work on geography or history.
TSI

TSI, a city of China, of the second rank, in Ho-nan; 242 miles S. of Peking. N. lat. 34° 30'. E. long. 112° 24'.

TSIA, in Botany, a name taken from the Japanese, and used by some authors for the tea-tree.

TSJAKELA, H. M.—Ficus Malabarica, femel in anno frutifera, frutti minima, a species of fig-tree growing in Malabar. Of the bark of this tree they make figs for their bows, and prepare a red colour for dyeing the Cambavan cloths.

TSIAM PANGAM, a name used by some authors for the tree whole wood is the log-wood, used in dyeing, and in medicine.

TSIAMAJA, in Geography, a town of Laos; which see.

TSIAMPA. See CHAMPA.

TSIANA EUA, in the Medita Medica, a name given by some authors to the colts root.

TSIAO, in Geography, a city of China, of the second rank, on the south coast of the island of Hai-nan; 125 miles S.S.W. of Kiong-techeou. N. lat. 18° 20'. E. long. 108° 25'.—Alfo, a town on the west coast of the island of Morty. N. lat. 2° 5'. E. long. 128° 18'.—Alfo, a lake of China, in Kiang-nan, about 60 miles in circumference; 42 miles S.W. of Nang-king.

TSIAO-TING-CHAN, a town of Corea; 50 miles E.N.E. of Koang-techeou.

TSIAO-TONG, a town of Corea, on an island of the same name. N. lat. 37° 48'. E. long. 124° 14'.—Alfo, an island in the Hoang-hai, or Yellow sea, near the coast of Corea, about 35 miles in circumference. N. lat. 37° 44'. E. long. 124° 54'.

TSIASSEM, a kingdom of the island of Java, on the north coast, E. of Caravang.

TSIBBA, a town of Japan, in the island of Niphon; 30 miles E.S.E. of Jedo.

TSI-CHU, in Botany, the name of a Chinese tree, which furnishes the liquor of which they make their celebrated varnish.

TSIEN, in Commerce, a weight in China. The Chinese weigh gold and silver by the gin or catty, of 16 lyangs or taels; and the lyang is subdivided into 10 tenins or maces, 100 fenins or candarines, and 100 lis or cash. The gin is the Chinese denomination for this weight, and the catty that of the European. See TALE.

TSIEN-OUYEY, in Geography, a town of Chinese Tartary; 40 miles S.W. of Ning-yuen.

TSIERIDON. See CHERIBON.

TSIJA, a town of Tibet; 48 miles W. of Contchoulong.

TSIKUMMA, a town of Japan, in the island of Niphon; 88 miles W. of Meaco.

TSILLI, a town of Corea; 35 miles W. of Sing.

TSILKANI, a town of the principality of Georgia, in the province of Carduel; 20 miles N.W. of Telis.

TSILON-PALHASIN, a town of Chinese Tartary, in the country of the Mongules; 13 miles S. of Oulan.

TSIM-YUEN, a town of Corea; 650 miles E.N.E. of Peking. N. lat. 42° 28'. E. long. 120° 54'.

TSIN, a city of China, of the second rank, in Chen-fi; 620 miles S.W. of Peking. N. lat. 34° 35'. E. long. 105° 24'.—Alfo, a city of China, of the second rank, in Hou-quang; 645 miles S.S.W. of Peking. N. lat. 26° 36'. E. long. 109° 4'.

TSIN, or Tsin, a town of Corea; 188 miles S.S.E. of King-ki-tao. N. lat. 34° 52'. E. long. 127° 44'.

TSIN, in Natural History, the name given by the Chinese to a stone which they make great use of in their manufacture of porcelain ware. It is of a deep blue colour, much resembling Roman vitriol in appearance, and is found in lead-mines, and supposed to contain some particles of lead; its effects being the fame in the porcelain manufacture as those of cerufs, or white lead, in making the other colours penetrate into the substance of the vefils. The deep violet colour that we fee so beautiful on the china-ware, is usually made with this stone. They find it about Canton and Peking; but the latter place affords the belt, and it sells at greatly the best price.

The painters in enamel melt this stone in their way, and use it very much; they form many beautiful works, by laying it upon fiver; but it is apt to come off in time. When the tfin is used in the porcelain manufacture, it is only used to the vases that pass a second baking, and are intended as the best kinds.

The tfin is prepared by only heating it to powder, not roasting it in the common way. They mix the powder with large quantities of water, and airing it together, they let it subside a little, to separate any earthly or extraneous matter that might be among it. They then let the powder subfide. The water which is thrown away has no colour from this matter, and the powder itself is not of that fine blue it was in the lump, but of a pale afh-colour; but this recovers all its beauty when it is laid on the china and baked. The settlement taken from the water is dried and preferred in powder, and when it is to be used, they only mix it up with gum-water, or a solution of glue, and lay it on with a pencil. Obscur. fur les Colories de Pafie.

TSI-NAN, in Geography. See TCI-NAN.

TSINCHAN, a town of Corea; 13 miles N.W. of Sing.

TSIN-CHOUI, a river of China, which runs into the Yuen, near Meyang.

TSINEN, a town of Asiatic Turkey, in Natoilia; 16 miles W.N.W. of Mogia.

TSING, a city of China, of the second rank, in Chan-fi; 267 miles S.S.W. of Peking. N. lat. 36° 42'. E. long. 112° 24'.—Alfo, a lake of China, in Kiang-nan, 22 miles in circumference; 45 miles N. of Hoai-ning.

TSING-HING, a city of China, of the second rank, in Yun-nan; 1162 miles S.S.W. of Peking. N. lat. 24° 47'. E. long. 102° 30'.

TSING-KIANG, a city of China, in Kiang-nan, on the Yang-tse river; 50 miles S.E. of Yang-tcheou.

TSING-LAN-OUEI, a town of China, in Hou-quang, near the source of the river Yuen; 25 miles S.W. of Hoang.

TSIN-KIEN, a river of China, which runs into the Hoang; 12 miles E.S.E. of Yen-tchan.

TSIN-NING, a city of China, of the second rank, in Chen-fi; 585 miles W.S.W. of Peking. N. lat. 35° 30'. E. long. 105° 25'.

TSINO, a town of Japan, in the island of Awaifi; 10 miles N. of Awaifi.

TSINRAMA, a town on the west coast of the island of Celebes. S. lat. 5° 10'. E. long. 119° 14'.

TSIN-TCHUEN, a town of Corea; 40 miles S.E. of Hoang-tcheou.

TSIN-YANG, a river of China, which rises near Tei-hia, in Chan-tong, and runs into the Eastern sea, near Fou-cha.

TSIN-YUEN-OUEI, a forftres of China, in Chen-fi, near the great wall, on the river Hoang; 75 miles N. of Limgtao.
TSISAGATA, a town of Japan, in the island of Nippon; 110 miles W. of Macao.

TSISIR, a town of Thibet, now in ruins. N. lat. 34° 14'. E. long. 60° 19'.

TSIT, a lake of Thibet, 45 miles in circumference. N. lat. 33° 32'. E. long. 95° 39'.

TITICHICHAR. See TITCICAR-HOTUN.

TSURAC, a river of Natolia, which runs into the Meander, at Telsarhebes.

Tso, a city of China, of the second rank, in Pe-tche-li; 22 miles S.S.W. of Peking. N. lat. 39° 32'. E. long. 115° 39'.—Allo, a city of China, of the second rank, in Quang-fi; 930 miles S. of Peking. N. lat. 22° 42'. E. long. 106° 49'.

TSO-CHOU, a town of Corea; 55 miles S.E. of Kang-tdcheou.

TSUKAMA, a town of Japan, in the island of Nippon; 170 miles W. of Macao.

TSOL-ABAD, a town of Asiatic Turkey, in Carmania; 32 miles S.W. of Akkhehr.

TSONDUE, a town of Thibet; 7 miles W. of Painom-Jeung.

TSONG-HE, a town of Corea; 10 miles N. of Hoang-tdcheou.

TSONG-KING, a city of China, of the second rank, in Set-tcheuen; 857 miles S.W. of Peking. N. lat. 30° 38'. E. long. 103° 23'.

TSONG-MING, a town of China, in the island so called. N. lat. 31° 45'. E. long. 120° 51'.

TSONG-MING, or Tjung-ming, an island near the coast of China, in the Eastern sea, at the mouth of the Yang-tse river, belonging to the province of Kiang-nan, about 50 miles in length, and 10 in breadth. This island was formerly a place of banishment for criminals, to whom some poor Chinese families returned, and they divided the lands amongst them; but not being able to clear all the land they had appropriated to themselves, called other families from off the continent to their assistance, and yielded to them for ever a part of the lands, on condition that they should pay annually, in divers goods, a rent proportional to their harvest. The country is divided by an infinite number of canals, that have high banks to defend it from inundations, for the land is level, having no hills; the air is healthful and temperate, and the country agreeable. Here are large towns scattered about the island at convenient distances, wherein is a great number of shops, well furnished with all manner of necessaries and conveniences of life; and, dispersed between each town, there are as many houses about the country as there are families employed in tillage. The highways are very narrow, and are bordered with little shops that sold refreshment to travellers; and, indeed, one would imagine the whole island to be one exceeding large village. Here are no wild fowl, but great numbers of large geese, ducks, hens, hogs, and buffaloes, but these latter are used only for tillage. The land is not alike throughout the island, the produce of it being very different: that towards the north is not cultivated, but the reeds which grow here naturally produce a considerable revenue; as there are no trees in the whole island, they use part of these reeds to build houset in the country; the other part serves to burn, and supplies fuel not only for the whole island, but also for some parts of the neighbouring continent. The second fort of land is that which extends from the first quite to the sea on the south side; this produces two crops every year; one of grain, which is generally in the month of May, the other of rice, or cotton; of rice, in September; of cotton, a little later:

their grain is rice, wheat, barley, and a sort of bearded corn, which, though it resemble wheat, is nevertheless of a different nature. There is a third fort of land, which, though it appear barren, produces a greater revenue than all the rest; it consists of a whitish earth, found in several parts of the north side of the island, from whence they get much a great quantity of salt, that it supplies not only the island, but part of the continent. In this island there is a number of mandarins, and the governor is one of those called literati." He alone administers justice, receives the tribute paid by every family to the emperor, gives passports to ships, and passes sentence of death on criminals. When the people have occasion for rain, or fine weather, this mandarin proclaims a general fast; butchers and inn-keepers are then forbid to sell any thing, under the severest penalties; they however take care to get rid of their provisions, by paying some money privately to the officers of the tribunal, whose business is to enforce the observance of this order. The mandarin afterwards walks in procession, accompanied by his subalterns, to the temple of the idol whom they intend to invoke; he kindles on the altar two or three small aromatic twigs; they then all sit down; to pass the time, they drink tea, smoke, and converse an hour or two; after which they retire. This is what they call begging for rain or fine weather.

Father Jacquemin relates, that in his time the viceroy of one of the provinces, becoming impatient because rain had not been granted to his repeated requests, sent an inferior mandarin to tell the idol, from him, that if it did not rain before a certain day he would drive him from the city, and cause his temple to be razed. No rain having fallen before the day mentioned, the viceroy, in a great passion, forbade the people to carry, according to custom, their offerings to the idol, and ordered the temple to be shut, and the gates sealed up, which was immediately executed. N. lat. 31° 38'. E. long. 120° 54'.

TSONG-SIO, a town of the kingdom of Corea; 27 miles S.E. of Hoang-tdcheou.

TSO-PING-ING, a town of Corea; 30 miles S.E. of Kaoang.

TSOR, or Son, or Sur, or Sor, a town on the east coast of Arabia, in the province of Oman; 22 miles S.E. of Kalhat. N. lat. 23° 50'.

TSORLI, or Ciorli, or Teweri, a town of European Turkey, in Romania; 15 miles N.E. of Rodosto.

TSOTSANG, a river of China, which runs into the Hoang, near Honi-king.

TSUBSUKI, a town of Japan, in the island of Nippon; 65 miles N.N.W. of Macao.

TUEN, a city of China, of the second rank, in Quang-fi; 912 miles S.S.W. of Peking. N. lat. 25° 56'. E. long. 110° 44'.

TUEN-TCHEOU, a city of the first class in China, in the province of Foc-hien, and reckoned one of the most beautiful cities in China, on account of its situation, extent, trade, triumphal arches, temples, and its well-paved streets. It has in its district seven cities of the third class. In its neighbourhood is a bridge remarkable for its extraordinary size, and the singularity of its construction. It was built at the expence of one governor. It is wholly built of the fame kind of blackish stone, without arches; but it has above 300 large stone pillars, which terminate on each side in an acute angle, the more easily to break the violence of the current. Five fenes of equal size, laid transversely from one pillar to another, form the breadth of the bridge; of these there are 1100, all of the
fame sixe and figure. On each side there are buttresses or props, constructed of the same kind of stone, on the tops of which are placed lions on pedestals, and other similar ornaments. This is merely one part of the work,—that which is between the small city of Lo-yang and the castle built upon the bridge: for beyond the castle there is another part, equally stupendous with the first.

TSUGA, a town of Japan, in the island of Niphon; 45 miles W.N.W. of Nambu.

TSUGARA, a town of Japan, in the island of Niphon; 62 miles N. of Jedo.

TSUI-TSANG, a town of Corea; 40 miles W.S.W. of Sing.

TSUKU-KI, a town of Japan, in the island of Niphon; 36 miles N.N.E. of Jedo.

TSUNTNI-TZ, a town of Croatia; 16 miles W. of Damianovitz.

TSUN-Y, a city of China, of the first rank, in Szechuen; 890 miles S.W. of Peking. N. lat. 27° 38'. E. long. 106° 33'.

TSUR. See Tsur.

TUA, in Ancient Geography, an estuary on the south-eastern side of the Isle of Albion, between the estuary Vayg, or Firth of Tayne in Sunderland, and the mouth of the river Celnas, or the Spay, in the shire of Elgin. The Tua was therefore Cromarty, or Murray Firth.

TUA, in Geography, a river of Portugal, which runs into the Duero, 15 miles N.W. of St. Joao de Pequeira.

TUABO, a town of Africa, in the kingdom of Jaen, on the side of the Senegal. N. lat. 14° 56'. W. long. 10° 28'.

TUACA, a town of Africa; 10 miles S. of Mombaça.

TUA, a small island in the Red Sea, about 12 miles from the coast of Arabia. N. lat. 5° 58'. E. long. 41° 58'.

TUAH, a port-town of the county of Galway, Ireland, which is represented in the "New Traveller's Guide for Ireland," as "a large, populous, well-built town," but which Dr. Beaufort calls, though an archiepiscopal see, a very poor city. It may have been improved since the publication of Dr. Beaufort's work, but the other account must be received with caution, especially when it speaks of "by-lanes and alleys, and the Suburb, filled with an industrious populace and working mechanics." It may, however, have a considerable retail trade, and may have derived great advantage from the introduction of the linen manufacture into its neighbourhood. The archbishop's palace is a spacious, venerable structure. The cathedral is a neat, but not extensive, edifice, which serves also for the paroch-church. Tuan lost its privilege of being represented in parliament at the Union. It is 93 miles W. from Dublin, and 16 miles N. by E. from Galway.

TUAH, an archiepiscopal see in Ireland, being the lowest in dignity of the four, and having the smallest jurisdiction; the number of benefices in this province being only 87, whilst in Armagh there are 415, in Dublin 252, and in Cahir 362. The fee of Tuan contains the greatest number of acres of any fee in Ireland, extending over a great part of the counties of Galway and Mayo, and including a part of Roscommon; yet such is the want of cultivation, and the poverty of the country, that it was found necessary to unite the bishopric of Ardgagh in the province of Armagh, to enable the archbishop to support the dignity of his station. The number of parishes is 89, forming 23 benefices, and having 24 churches. The chapter consists of a dean, a provost, an archdeacon, and eight prebendaries. The suffragan bishoprics are those of Clonfert, Elphin, and Killaloe.

TUAPE, a town of New Navarre; 160 miles S. of Cala Grande.

TUARIK, a people of Africa. The west and south of Fezzan, says Mr. Horneman, is inhabited by the Tuariik, a mighty people, who border south-west on Bornou, south on Bornou, Soudan, and Tombutcoo, eastward on the country of the Tibbo and Fezzan, northward on part of Fezzan and the Arabs who live behind the regions of Tripoli, Tunis, and Algiers, and westward on the great empire of Fez and Morocco; of whom a few colonies are found in Sockna, Auela, and Sisath; in such places, the language of the Tuariik is the only one spoken by the inhabitants. The Tuariik are divided into many nations and tribes, who all speak the same language. The Tuariik of Hagara and Kolluvii are thin in growth, rather tall than short, their walk firm but firm, their look stern, and their whole demeanour warlike. Cultivated and enlightened, their national abilities would render them perhaps one of the greatest nations upon earth. Their character, particularly that of Kolluvii, is much esteemed. The western tribes are white, as much as the climate and manner of living will admit. The Kolluvii, who reached the region of Abun, and conquered Agades, and mixed with the nations, are of different colours, many of them black, but their features are not like those of negroes. The Hagara and Mustara tribes are yellowish, like the Arabs; near Soudan there are tribes entirely black. They are not all Mahometsans. In the neighbourhood of Soudan and Tombutcoo live the Tegama, who are white and pagans: they carry on a commerce between Soudan, Fezzan, and Gaudames. Their caravans give life to Mourzouk, which without them is a desert; for they love company, song, and music. The greater part of the eastern Tuariik lead a wandering life.

TUAT. See Twat.

TUB, in Gardening, a fort of hrong upright boxes, calculated for containing large green-house exotics, and other potted plants and trees, when grown too large for the pots. These tubs are made by the cooperers proper for this purpose, somewhat in the garden-pot form, a little wider at than at bottom, from a foot and half to two feet and a half deep; the width in proportion; constructed of the strongest thick staves and bottoms, and well hooped with iron, and with two iron handles at top, by which to remove them; these handles being iron, and generally hooked, especially in very large tubs, in order to receive a pole in each occasion, that the tub and plant together may be more readily moved. The bottom of the tubs have auger-holes bored in different parts, at regular distances, by which to discharge the superfluous moisture, after watering, &c.

In tubbing large-grown plants, they should be removed from their present pots, with the balls of earth about their roots entire; and having earthed the bottom parts of the tubs, the plant should be set in with its whole ball of earth, filling up properly around, and an inch or two over the top of the ball, with more fresh mould, and then watering.

See Shifting of Plants, and Potting.
TUB-Feed, in Ichthyology, an English name given to a species of trigla, sometimes called the flying-feet. See Trigla.

Tun-Man, in the Court of Exchequer. See Precedence.

TUBA, in Antiquity. See Trumpet and Luteus.

Tuba, in Natural History, a name by which many old authors call the cuttisum.

Tuba, in Geography, a river of Russia, which runs into the Enifei, 16 miles S.W. of Abakanfs, in the government of Kolivan.

TUBAI, one of the small Society Islands, in the South Pacific ocean; about 12 miles from Bolabola. S. lat. 16° 12'. W. long. 151° 44'.

TUBANSKA, a town of Russia, in the government of Irkutsk; 44 miles N.W. of Ilimfik.

TUBANTES, in Ancient Geography, a people of Lower Germany, on the other side of the Rhine. According to Cluver, they at first inhabited the country now called the counties of Ruenberg and Lippe; and from hence they traversed the territory which lies between the Rhine and the Elbe.

TUBAON, in Geography, a town on the north coast of the island of Java. S. lat. 5° 52'. E. long. 112° 14'.

TUBBAULEH, a town of Hindoolan, in Lahore; 10 miles S.S.W. of Callanore.

TUBBER, in Mining, a name given in Cornwall to that mining instrument, which is in other parts of England called a bolo.

TUBBER-Men, in Cornwall, the people who work with this tool, and who are, from its other name of bolo, called in other places beel-men.

TUBBERMORE, in Geography, a part-town of the county of Londonderry, Ireland, which is 90½ miles N. by W. from Dublin.

TUBE, TUBUS, pipe, conduit, or canal; a cylinder, hollow within, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

The term is chiefly applied to those used in physics, astronomy, anatomy, &c. On other ordinary occasions, we more usually say pipe.

In the Memoirs of the French Academy of Sciences, M. Varignon gives a treatise on the proportions necessary for the diameters of tubes, to give precisely any determinate quantities of water. The refuit of his piece turns upon these two analogies; that the diminutions of the velocity of water, occasioned by its friction against the sides of tubes, are as the diameters; the tubes being suppos’d equally long; and the quantities of water issuing out of the tubes, are as the square roots of their diameters, deducting out of them the quantity each is diminished.

For the tubes of barometers and thermometers, see Barometer and Thermometer. For the ascent of liquors in capillary tubes, see Ascendent and Capillary.

TUBE, in Astronomy, is sometimes used for telescope (which see); but more properly for that part of it into which the lenses are fitted, and by which they are directed and used.

The goodnes of the tube being of great importance to that of the telescopes, we shall here add its structure.

The Construction of a Draw-tube for a Telescope.—The chief points to be regarded here are, that the tube be not troublesome by its weight, nor liable to warp and disturb the position of the glasses; so that any kind of tube will not ferve in every place: but,

1. If the tube be small, it is best made of thin brass plates covered with tin, and formed into pipes or drawts, to slide within one another.

2. For long tubes, brass or iron would be too heavy; for which reason, some chafe to make them of paper, thus: a wooden cylinder is turned, of the length of the paper, and of a diameter equal to that of the smallest draw. About this cylinder is rolled and pasted paper, till it be of a sufficient thickness: when one tube is dry, provide others after the same manner; still making the last ferve for a mould for the next, till you have enough for the length of the tube desired. Lastly, to the extremities of the drawts are to be glued wooden ferrills, that they may be drawn forth the better.

3. Since paper drawings are apt to swell with moist weather, so as to spoil their sliding; and in dry weather to shrink, which renders them loose and tottering; in both which cases, the situation of the ferrills is easily disturbed; the best method of making tubes is as follows: glue parchment round a wooden cylinder, and let the parchment be coloured blue, to prevent the reflected rays making any confusion. Provided every this slits of beech, and bending them into a cylinder, glue them carefully to the parchment; cover this wooden case with white parchment, and about its outer extreme make a little ring or ferril: after the same manner make another draw over the former; and then another, till you have enough for the length of the tube.

To the inner extremities of each draw, fit a wooden ferrill, that the furious rays, striking against the sides, may be intercepted and loft. In those places where the ferrills are to be put, it will be proper to furnish the ferrills with female screws. Provide a wooden cover to defend the object-glafs from the dust, and putting the eye-glafs in its wooden ferrill, fasten it by the screw to the tube. Lastly, provide a little wooden tube of a length equal to the distance the eye-glafs is to be from the eye, and fit it to the other extreme of the tube.

Tubes, or Pipes, among Florists, is that part of a fine flower which has something of a straw-like pipe or opening; and which, to constitute a good flower, in some sorts, as those of the auricula and polyanthus, should stand exactly in the centre of the blofom, and have a truly round or circular form; be well filled with chives or little thread-like parts, something in the manner of a brush at their points, rising even with the face of the pip or blofom; as when only the style or point of ripes like a pin, without being surrounded or encompassed with the chives to the same height, the flower is said to be pinned, and displays a chafm or vacancy, which is to very unpleafant to the eye of the curious in flowers, that though, in many other respects, such flowers may have good properties, yet failing in this central perfection and beauty, nothing else can atone or make up for it; and such flowers are, of course, held in but small estimation by the florist. See Tube and Tubs.

Tubes, in Artillery, are instruments used in quick firing, made with us of tin; their diameter is two-tenths of an inch, so as just to enter into the vent of the piece; their length is about five or six inches, with a cap above, and cut flanting below in the form of a pen, and the point is strengthened with some folder, that it may pierce the cartridge.

Through each tube is drawn a quick-match, and the cap is furnished with mealed powder, moistened with spirits of wine. To prevent the mealed powder from falling out by carriage, a cap of paper is tied over it, which is taken off when used; but of late this cap is made of flannel, steeped in spirits of wine, and with salpetre dissolved in it; and there
there is no occasion to take it off, because it takes fire as 
quicker as loose powder. The French use a small reed, to which 
is fixed a wooden cap, and they are about two inches long, filled with meale 
powder, moistened with spirits of wine; and a small hole is 
made through them of the size of a needle, through which 
the fire darts with great violence, and gives fire to the 
cartridge, which must be pierced before-hand with the 
priming-iron. 

These tubes may be kept a great while without being 
spoiled; but piercing of the cartridge retards the quickness 
of firing. Muller's Art. p. 293.

TUBE, Alimentary. See DUCT.

TUBE, Eustachian, or Trumpet, in Anatomy, a canal of 
communication between the throat and the tympanum. See 
EAR.

TUBE, Eustachian, Disease and Obstructions of, in Surgery. 
These are often a cause of a considerable degree of deaf-
ness, because it is necessary for perfect hearing, that air 
should be conveyed from the mouth through this passage 
to the cavity of the tympanum, which now can no longer 
happen.

A degree of deafness generally attends a severe cold, 
which is accounted for by the Eustachian tube being ob-
structed with thickened mucus. Mr. Saunders tells us, that 
the obstruction most frequently arises from syphilitic ulcers 
in the throat, or sloughing in the cysynanche maligna. The 
Deafness comes on when such sores are healed, that is, when 
the obstruction is complete. The defect of a nasal polypos 
into the pharynx, and enlarged tonsils, have also been known 
to close the tube.

When the Eustachian tube is obstructed, the patient can-
not feel the membrana tympani crackle, as it were, in his 
ears, or blowing forcibly with his nose and mouth stopped. 
Previous ulceration, or disease of the throat, will sometime 
times aid in facilitating the diagnosis.

When the Eustachian tube is obstructed with mucus, it has 
been proposed to employ injections, which are to be 
thrown, by means of a syringe and catheter, into the guttural 
orifice of that canal. This operation, however, is alleged 
to be always attended with trouble; and when the os spon-
gioseum inferius happens to be situated near the floor of 
the orbit, the introduction of any instrument like a female ca-
theter would be impracticable. Richerand Nofographie 
Chirurgicale, tom. ii. p. 131. edit. 2.

Mr. A. Cooper had noticed, that hearing was only im-
paired, not lost, when suppurations in the tympanum had 
injured, and even destroyed the membrana tympani; and 
that the degree of deafness by no means equalled what re-
Sulted from an obstruction of the Eustachian tube. Hence, 
when the tube was permanently obliterated, he conceived 
that a small puncture of the membrana tympani might be 
the means of enabling the patient to hear. Mr. A. Cooper 
practised the plan with success, and others have imitated him 
with the same success.

The operation consists in introducing an instrument, re-
sembling a hydrocele trocar, but curved, into the meatus 
auditorius externus, and pushing it through the anterior and 
inferior part of the membrana tympani; a place rendered 
most eligible, on account of the situation of the choorda 
tympani and manubrium of the malleus, parts which should 
not be uninjured. The instrument must not be introduced 
for, lest it should wound the vascular lining of the tym-
panum, and cause a temporary continuance of the deafness, 
by an effusion of blood. When the puncture is made, in 
proper cases, and in a judicious manner, hearing is immedi-
ately restored. A small hole in the membrana tympani now 
conveys the air into the cavity of the tympanum, answering 
the same purpose as the Eustachian tube.

The surgeon will be able to operate with more ease, if he 
take care to lessen the curvature of the meatus auditory, by 
drawing upward the external ear.

There is some chance of a relapse, in consequence of the 
opening closing up. This consideration has led Richerand 
to propose making the aperture with caustic, so as to de-
froy a part of the membrane. (Nofographie Chirurgicale, 
tom. ii. p. 132. edit. 2.) The fuggation is not, however, 
likely to be adopted, on account of the inconveniences of 
applying caustic within the ear. Mr. Saunders is an advocate 
for making the opening large. This gentleman relates, 
that he infamously returned hearing in one case, in which 
the patient had been deaf thirty years, in consequence of a 
loft of part of his palate by typhilitis. Mr. A. Cooper's 
cases are in the Philosophical Transactions for 1802.

Puncturing the membrana tympani has been attended with 
some degree of success in France, as well as this country. 
It is not to be dismembled, however, that there are 
numerous failures. We are informed that professor 
Dubois has done the operation in four instances, without 
success. Richerand Nofographie Chirurgicale, tom. ii. 
p. 132.

In most cases, the patients who have been benefited, are 
fai'd to have experienced pain just after the trocar was 
withdrawn. The organ, in consequence of not being accu-
Eimated to found, has become so extremely fefible, that it 
could not bear the gentlest impression of the fonorous vibra-
tions; and the patient's firit request, after the perforation 
was made, was that they who were near him might speak 
softly. This exceffive tenderness of the feme gradually 
Eubidies.

TUBES, Fallopian, or Trumpets, in Anatomy, two small 
canals, forming communications between the cavities of the 
uterus and abdomen, and serving to convey the germs of 
the new beings, in generation, from the ovaries to the uterus. 
See Generation.

TUBE, Glass. See GLASS-TUBE, LAMP-Blower, and 
Hermetical Seal.

In order to bend a glafs-tube, if the glafs is pretty thick, 
and the bore narrow, it may be held in the weaker part of 
the lamp-flame, and softened for about an inch or two of its 
length, and then bent flowly into any required shape. But 
if the tube be wide, and the glafs thin, this mode of bending 
will entirely destroy the cylindrical form of the bore at the 
part that is bent, making a double flattening. In order to 
avoid this, first felf up one end of the tube, and then, whilft 
bending it at the required part, blow feadily and gently 
into the open end, and the pressure of the breath will coun-
tera the fulling in of the fides of the bending portion, and 
keep the bore cylindrical. The closed end is then cut of 
by the flie; for which purpole, make a deep scratch with 
eone edge of a fine three-cornered file on the part intended 
to be cut, then break the tube with a smart pull in that direc-
tion in which the scratched part will be outermost; and it 
will in general separate accurately at this point.

In order to join two tubes, heat them both in the flame, 
and apply them together, when quit hot, turning them round 
to finifh the confolidation; or elfe, to avoid the thick 
ring of glafs which this produces, previously close one end 
of one tube, and when the two ends are fully joined, blow 
into the open end of the other tube, and pull them out a little 
at the point of juncture, till an equal cylinder is formed.

To form a bulb (e.g. of a thermometer), chufe a tube 
of
of a very equal bore, seal the end in the usual manner, and to collect a greater mass of glafs at the end, press upwards on it while quite hot with any iron instrumen, fo as to con- solidate and shorten it a little; let it remain in the hottest part of the flame, till the lump of glafs is quite white hot; then remove it, put your lips to the open end without loss of time, holding it with the hot part loweft, and blow moderately and steadily. The lump of hot glafs will immediately open into a bulb, the size of which may be regulated at pleasure.

TUBE, Stentorophonic and Torricellian. See the adjectives.

TUBEPILLY, in Geography, a town of Hindooftan, in Mylfo; 20 miles W. of Chenna Balabaram.

TUBEL, a word used by some chemical writers to express scales of copper or brass.

TUBELDIE, in Geography, a town of Dar-Fur; 180 miles S. of Coblé.

TUBER, or TUBERCLE, in Botany, a kind of round tubgird root, in form of a knob or turnip.

The plants which produce such roots are hence denominated tuberof, or tuberous plants. See TUBEROUS Roots.

Eff. Ch. Roundish, feshy, solid, closed; its substance variegated with veins bearing beaten.

1. T. cervinum. Common Truffle. Perf. n. 1. With. 1. Bulliard. v. 1. 74. t. 356. Sowerb. Fung. t. 309. (T. brumale, pulpa obfcuris odoris; Mich. Gen. 221. t. 102. Tuber; Tourn. Int. t. 333. T. terre; Gen. Em. 1583.)—Blackish, rough with prominent warts. Found under the surface of the ground in moift parts of Europe, where the soil is light and dry; as well as in Japan, and the East Indies. Dogs are taught to find this fungus by the smell, and to feratch it out of the earth. It is brought to table, either finely boiled, or flewed in various forms.

The French and Italians introduce truffles into different made dishes, sauces, pies, &c. They are reported to have a stimulating, or aphydiacal quality, which, whether imaginary or not, perhaps renders them more popular than their flavour, which is trifling. The size of this fungus is about that of a walnut in its outer coat, but the surface is irregularly tumid, and harsh to the touch from innumerable fhab warts. The inner subsance is greyish, or pale brown, with numerous curved branching veins, lodging the minute feeds. No signs of a root are observable.

There are said to be several variations of colour in this species.

2. T. magnum. Musky Truffle. Bulliard v. 1. 79. t. 479. Perf. n. 2.—Blackish, smooth.—Native of France. Like the foregoing in size, and general figure; but its surface is smooth, the internal subsance rather soft, and the fcent musky. By drying the coat becomes wrinkled. Bulliard.

3. T. griseum. Grey Truffle. Perf. n. 3. (Truffle grise; De Borch Truffes du Piemont, 7. t. 1. 2.)—Roundish, irregular, smooth, soft, greyish-achicoloured.—Native of Piedmont, in a light, moderately moist, soil. The size of the two preceding, but more irregular in shape, of a foapy texture and light colour, with a strong fcent of garlic.

4. T. album. White Truffle. Bulliard v. 1. 80. t. 304. Perf. n. 4. With. n. 2. Sowerb. Fung. t. 310.—(Bianchetti; De Borch Truff. du Piem. 6. 7.) Lycoperdon gibbosum; Dickf. Crypt. fale. 2. 26.—Light reddish-brown, roundifh, half above ground; veins rufly-coloured.—In woods, in England and France, also in Greece, but partly funk in the earth. The outide is smooth, turning more yellow in drying; the inner subsance refembles rhubarb. Its flavour is faid to be difagreeable.

Dr. Withering defcribes a variety, or more probably, as he obferves, a different species, whose internal subsance is uniform, like coar, of the hue of tanned leather; the surface knobby and pitted, hairy in the pits. The whole mass perforated by items of grafs; fo that it muft have been above ground in a soft flafe.

5. T. effimum. Summer Truffle. Mich. Gen. 221. n. 2. (T. album 3; Perf. n. 4). Lycoperdon effimum; Wulf. in Jacq. Coll. v. 1. 349.—Nearly globular, smooth, brown, or blackish; fpongy within; entirely subterraneous.—Plentiful in Carinthia and Carniola from May to Auguft. These have little tafte or smell, but are used much for the table. When young the surface is whitifh and fealy, but gradually becomes brown or blackifh. Their fize is equal to a chufnut or walnut. Perhaps, as Perfoon thought, this may not be a different species from the laft.

6. T. cervinum. Baldart Truffle. With. n. 3. (Tu- berca cervina; Lob. Ic. v. 2. 276. Lycoperda trium tumefcens arfihon fulvum, cortice duriofo crafo et granulato, medullü ex albo purpuraceo, femine nigro caffio; Mich. Gen. 220. t. 99. f. 4.)—Globular, finely granulated, rather folid, finally burfting; powdery in the centre. Found barely funk in the ground, in several parts of England, as well as in Bohemia and Silefia, about Sep- Tember. The diameter is about an inch and a half; the outide hairy; inner subsance, or nucleus, purplifh.

7. T. solidum. Hard Truffle. With. n. 4. (Lycoperdon cepa facie; Vaill. Parif. t. 16. f. 5. 6.)—Glo- bular but comprifed, (rather depreffed,) brown, reticulate, very firm; blue-black within. —Found in Dr. Withering's park at Edgbaston, near Birmingham, under an oak-tree by the pool, in Auguft. This had a flert root, as Vaillant repreffes it, and appears to be, as Mr. Sowerby fuppofes, only a nearly feffile variety of his Lycoperdon defulfum, Engl. Fung. t. 311.

Found on heaths, and in woods, in Italy and England in the fummer, but rare. Two or three inches in diameter, folid, never burfting, nor becoming internally powdery. The outer skin is brown, or olive, cracking into angular portions, but not warty. Inner subsance purplifh, veined with black; finally quite black. Apparently different from Lycoperdon aurantium of Bulliard, t. 270; fo that the fine fmoke in his figure may not be altogether, as Bolton fays, "conjeftural;" it may reprefent the powdery feeds, eloping from holes eaten by insects, as Bolton himfelf fuppofes.

TUBER, or TUBEROUS, in Surgery, is used for a knob or tumour growing naturally on any part; in opposition to tumours which rise accidentally, or from a difeafe.

The fame term is also used for a knot in a tree.

TUBERA TERRÆ. See TRUFFES.

TUBERAN, in Geography, a town of Perfoa, in the province of Kerman; 171 miles N.E. of Sebirs.

Vol. XXXVI.
TUBERCLE, a small, hard, superficial tumour, circumcised, and permanent, or suppurating partially.—Batesman's Synopsis of Cutaneous Diseases.

TUBERCULA QUADRIGEMINA, in Anatomy, a part of the brain. See Brain.

Eff. Ch. Roundish, compact, smooth, permanent, soluble in wet.

2. T. vulgaris. Scarlet Tubercularia. Tode 18—20. t. 4. f. 30. Perf. n. 2. (Tremella purpurea; Linn. Sp. Pl. 1626. Huds. 565. Lichenoides tuberculodam amoenae purpureum; Dill. Mufc. 127. t. 18. f. 6.)—Aggregate or scattered, bright red, corrugated, with a thick pale base. Very common on dead or dying branches of trees, especially currant-bushes, where it becomes conspicuous by its scarlet or deep-red colour.

3. T. granulata. Dull Granulated Tubercularia. Perf. n. 3. —"Roundish, dull red, with a corrugated granulated surface."—On the branches of Sycamores, or other species of Acer, but rare. Its colour is brownish and opaque; yellowish within. Perf. 11.

5. T. ciferante. Chefnut Tubercularia. Perf. n. 5.—"Scattered, small, sunk in the bark, flattish, very smooth, bright red."—On the bark of the chefnut-tree. Half the size of T. vulgaris, and scarcely projecting out of the cuticle of the bark. Its colour externally is like that of a strawberry, the infide yellowish, firm.

6. T. rofo. Rosy Tubercularia. Perf. n. 6. Obf. Mycol. n. 137. fasc. 1. 78. (Lichen rofeus; Schreb. Lipf. 140.)—Scattered, loofe, irregularly globulo, rose-coloured. —On trees, especially adhering to Lichen felleria, parietinus, &c. We have found it on the former at Hetherfet, near Norwich. The bright-pink little mafles, of which this species confifts, might be taken for the tubercles of fonie Lichen; but they diffole in wet.

TUBERCULUM ANNUARE, in Anatomy, a part of the brain. See Brain.

Tuberculium Loweri, a small eminence in the right auricle of the heart. See Heart.

Tubercinense Ophiium, Tubernoke, in Ancient Geography, a town of Africa, built in form of a crecent, between the fummits of a mountain, 7 leagues S.W. of Tunis.

Tubernoki, in Geography, a town of Tunis, anciently the see of a bishop; 21 miles S.S.E. of Tunis.

Tuberose, in Botany, see Polianthaceae. This English name is not compounded of tuber and rofe, as most people would naturally conceive, but originates in the old appellation of Tuberofe, or Tuberosus, Hyacinth, Hyacinthus tuberosus; alluding to the tuberous root, and the refulance of the flower to a Hyacinth.

Tuberous Roots, in Gardening and Agriculture, such as confift of one or more swelled or knobbed tubers, of a folid fleshy fubftance. In this tribe are comprifed many plants of the ornamental flowery kind, and fome efeuents of the kitchen garden; as in the former, anemone, ranunculus, filipendula, many forts of iris, aconitum, paixon, orchis, cyclaen, winter-aconite, day-lily, &c.; fome also with bulbous tuberous roots, as gladiolus, polianthes and tuberofe, ophrys, &c.; and of the efficient tuberous roots are the potatoe and Jerusalem artichoke; all of which plants are principally per- manent in their roots, being perpetuated annually by offsets, or cuttings for fets. See Root.

It has lately been fuggfted, and in fome meafure confirmed by experiment, that, in cultivation, the root of this kind, called the potatoe, is liable to have the difefe termed the curl produced in crops of it, by the tubers which are used for feed-flock or fets having been allowed to become too ripe the preceding year; and that this praftice of over- ripening, being repeated year after year, is the real caufe of the difefe, the vegetative power in the tubers being in this way exhausted.

It has been long known to all cultivators of this fotr of crops, that the ufual method of reproducing any particular variety of the root is by cuts or fets of the tubers; and that this manner of propagation is continued from year to year, as long as that particular fort is wished for, without ever thinking of reinvigorating the feed-flock, or tubers for planting, by raising new plants from the real feed; the species being reproduced only by fowing the true feeds of the plant. It is only thus that new varieties are obtained. But if feeds be taken from any particular variety which is wished to be preferred, and if care be exercised that the plants shall have no communication with the farina of any other plants of the same fpecies in flower, then the produce of these feeds will probably be the fame with that variety from which the feeds were faved; and from the feed-flock being renewed, and reinvigorated in this manner, it seems likely that the variety so obtained may, by observing a proper management, be preferred from this difefe, or any other kind of degeneracy, for any length of time.

This opinion of the over-ripening of the feed-flock for the supply of the ensuing year, by allowing it to remain too long in the ground, especially when planted early, and of the repetition and continuance of it rendering the tubers wholly unfit for producing vigorous healthy plants, by exhausting their power, being the chief caufe of this difefe, has however been almost uniformly objected to, as being quite contrary to experience in regard to feeds in general, as full ripenefs has been confidered the bell recommendation of them. It is notwithstanding apprehended, that this objection arises from the taking of an improper view of the matter. For though it be true, that all of what are properly called feeds are improved by being thoroughly ripened; the cuts or fets taken from the tubers of this fort cannot, strictly speaking, be confidered as feeds. The planting cuts of this kind of tuberous root, is analogous, it is suppofed, to budding or grafting of trees, being only a secondary mode of propagation, and consequently that such an objection cannot hold good. Besides, the fuggftion is illuftrated and supported by different other circumstances and confiderations, as well as by the well-known powerful caufe which weakens the vegetative power in the tubers,—that of allowing the plants that are intended for the supplying of feed-flock for the ensuing year to run to flower, and produce feed. This, it is thought, should in all cafes be prevented, by cutting off the flowers as they appear in their embryo state. In this way, by turning nature from her ordinary course, to force her to exert herfelf in another direction, and to throw back into the tubers that portion of the vital principle of the plant, which would have been ex- hausted in the formation of flowers and feeds. Nothing will, it is fuppofed, contribute more to prevent degeneracy in this fort.
fort of tuberous root, and especially of the disease to which it is so liable, than this treatment. See the first volume of the Transactions of the Scottish Horticultural Society.

**TUBERS, in Geography, a town of Tunis, anciently the see of a bishop; 48 miles S.W. of Tunis.**

**TUBIG, a town on the E. coast of the island of Samar.** N. lat. 12° 13'. E. long. 135° 27'.

**TUBILSTRIUM, compounded of tubus, trumpet, and lufus. I purify, in Antiquity, a fea or ceremony in use among the Romans. This denomination was given to the day on which they purified their sacred trumpets, as also to the ceremony of purifying them. It was held on the fifth and last day of the feast of Minerva, called quinquatrus, or quinquatrina, which was performed twice a year.**

**TUBINGEN, in Geography, a town of Wurttemberg, situated in a valley on the Neckar, between two hills. An university was founded here in the year 1477, and restored in the year 1770. Here is a seminary for the study of divinity, and a college for the nobility. The foundation of the town is unknown, but附属ed of great antiquity. It is the origin of the pfalzgrave of Swabia, and though the decent of the ancient palatines of Tubingen be unknown, yet they had their pfalz or palatium, which stood on the spot of the present castle. One of the eldest pfalzgraves known at present, lived in the year 1080; and the laft of them, viz. George Eberhard, died in the year 1631. The two pfalzgraves, Gobz and William, in the year 1342, fold the town to count Ulrich of Wurttemberg. In 1535, duke Ulrich, pulling down the old castle, caufed that of Hohen Tubingen, which is the present residence, to be erected, with fortifications. In 1540 the town was damaged by fire. In the thirty years' war it was frequently besieged and taken; and in 1688, was considerably injured by the French; 16 miles S.S.W. of Stuttgart. N. lat. 48° 34'. E. long. 9° 10'.**

**TUBIPORA, Red tubular Coral, in Natural History, a name given by Linneus to a genus of Zoophyta, in the class of worms; the characters of which are, that its animal is a sferis, and that it is a coral, consisting of cylindrical, hollow, erect, and parallel tubes. In Gmelin's edition of the Linnean System we have the following Species.**

**MUSICA. With fasciculated combined tubes; the transformate partitions membranaceous and distant. This is the purple tubipora of Pallas, of which he mentions a variety, or the flexuofe tubipora. It is found in the American, Indian, and Red seas, affixed to other corals or rocks; and is used by the Indians as an antidote to scurvy and wounds inflicted by poisonous animals.**

**CATENULATA. With parallel tubes, connected into a lamina anafoomening with a folded wreath. Found on the shores of the Baltic sea.**

**SERPENS. With cylindric, erect, very short, diantar, axillary tubes; divergently at the dichotomous base; the Millopora lilaceas of Pallas. Found in the Mediterranean and Northern seas, and on the shores of the Baltic.**

**FASCICULARIS. With filiform fasciculated tubes; the siles anafoomening. Found on the shores of Gotland.**

**RAMOSA. With roundish interfaces, and simple, flexuofe, aggregate, conglutinated tubes of the conoid branches. Found in the White sea.**

**PENNATA. Dichotomous, erect, with tubes distributed in the form of small feathers. Found in the Mediterranean sea.**

**PENICILLATA. Stalky; the top incrustated, and formed of tubes connected towards the base. Found in the Greenland sea, affixed to terraces.**

**FLABELLARIS. Depressed, flabelliform, radiated with parallel conjoined tubes. Found as the former.**

**STELLATA. With separate tubes, combined in layers or tables, many of these tables being remote, horizontally tubulous, and radiated with frizz on the surface. Found among fossils.**

**STRES. With diverging diverging tubes, loose behind and often bent; with tubes small, simple, and horizontal, combined. Found among fossils.**

**TUBINA, in Geography, a town of Algiers, anciently called Thubana. The Arabs bury their treasure under the ruins; 110 miles S.S.W. of Contantina. N. lat. 35° 3'. E. long. 5'.**

**TUBOBO, a town on the south coast of Mindanao. N. lat. 7° 40'. E. long. 124° 32'.**

**TUBUCUF, a town of France, in the department of the Mayence; 6 miles N.N.E. of Laflat.**

**TUBOR TERR. A, name used by some botanical authors for the cyclamen or bow-bread.**

**TUBUG, in Geography, a harbour on the west coast of Mindanao, much frequented by pirates. Near it is the house of a rajah, strongly palisaded, and defended with twenty fire-guns; 10 miles N. of Pollock harbour.**

**TUBUHACAN, a town of Africa, in the country of Sugulmea; 9 miles from Sugulmea.**

**TUBULARIA, in Zoology, a genus of the Zoophyta class of worms; the characters of which are, that the animal is vegetating and radiated; the head crested with tentacula, generating small eggs; and that the stem is tubulous, horny, very simple or branched, affixed at the bottom, and the animal thrills out at the apex. Among the following species are included several of the tubular corallines of Ellis.**

**Species.**

**CORNUCOPE. With fimbute tube, attenuated below, flexuous and rough. Found among the corals of the American and Mediterranean seas. Colour dusky-yellow.**

**INDIVISA. With very fimple flanks, and wreathed joints. One of Ellis's tubular corallines. Found in the European and Mediterranean seas. Colour yellowish-grey.**

**RAMOSA. With branched flanks, and wreathed joints: one of Ellis's. Found in the European sea. The soft tubes foridly grey.**

**RAMEA. With compound branched tubes, large and small branches alternate. Found in the Mediterranean ocean. Brownish-grey.**

**FISTULOSA. With dichotomous articulated flanks, with imprecisely in form of a rhombus. Bugle coralline of Ellis. Found in the European, Mediterranean, and Atlantic seas. Pale-grey.**

**FRAGILIS. With dichotomous flanks, and compressed joints. Found in the American sea. White or greenish.**

**MUSCOIDES. With sub-dichotomous flanks, wholly annulate-rugose. One of the tubular corallines of Ellis. Found in the European and Mediterranean seas. Pale-grey.**

**PAPYRACEA. With a very large papyrusceous tube, alternately ramose. Found in the Indian ocean.**

**PENICILLUS. With elongate, fimple, radiated tubes, proliferous and penicillated at the apex. Found in the American sea. It is doubted whether this is the last of this genus.**

**ACETABULUM. With filiform flanks; the terminal pelta or shield frirated, radiated and calcareous. Found in the Mediterranean and American seas. White and soft, and adapted to terrella.**

3 A 7

**Spalacnea**
Splachnea. With capillary very simple flasks; the terminal pelta smooth and membranaceous. Found in the Mediterranean sea. Of horn-colour.

Affinis. Simple, tub-annulated, soft; with the tentacula of the mouth encompassing the papilla attempted. Found on the English coast, adhering to fucet, and akin to the last. Fabric. Stellated, with pinnated cirrhæ, and six rays encompassing the mouth. Found on the shores of Norway and Greenland, often in the fisheries of rocks. Grey, green, or white.

Longicornis. With two setaceous cirrhæ, longer than the tubule. Habitation unknown.

Multicornis. With more than twenty cirrhæ centrally white; body round and hyaline, tubule mace-like. Habitation unknown.

Campulanata. With lunated creft; orifices of the vagina annulated; body concealed within the vagina. Found in the flagrant waters of Europe.

Repens. Crested, with cirrhæ on both sides radiated; vagina extended, tubule opaque, procumbent. Found in the flagrant waters of Northern Europe.

Reptans. With lunated creft; body tractile beyond the vagina. Found in the flagrant waters of Europe. Hyaline, soft, with about fifty cilia.

Sulcana. With infundibuliform creft, ciliated at the base. Found in the pools of Gottingen.

Stellaris. Crested, with pectinated cirrhæ, brown, annulated creft tubule. Found in the focus of the Baltic sea.

Simplex. With eight linear cirrhæ, and conic hyaline tubule. Found in the focus of the Norwegian sea.

Spallanzani. With five plumeo cirrhæ, pectinated on both sides, and cylindric, horny tubules, below incurvated. Found in the Mediterranean sea.

Membranacea. With a double concentric range of fistulous tentacula, and a membranaceous, contractile, vificid, cylindric tubule inclosing the inhabitant. Found in calm parts of the Mediterranean; but doubted whether it belongs to this genus.

Tubularia Fossili, in Natural History, the name of a species of coral found very often fossile in Germany and Italy, and composed of a great number of tubes, or longitudinal pipes, often resembling so many worms ranged perpendicular in the mafs.

They are usually found either in mafs of a lax flone, or in single tubules in thofe of the harder and firmer texture. In these two flates this fossile makes two very different appearances; and, according to the different directions in the mafs, or the different views of them that the fections of it place them in, they make a number of very elegant figures. Hill.

Tubulated Flower, Tubulatus floeolus, in Botany, a term used by authors to express thofe small flowers, a great number of which go to compose one large compound flower. Thofe are called tubulated, by way of distinction from another kind of them, which are, from their shape, called ligulated. The tubulated floeolæ generally compose the dkf, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal segments, which fland expanded, and in some measure bent backward.

Tubuli Concamerati, in Natural History, the name of a genus of the Tubulus marinus, distinguished abundantly from all the others by its figure and inner structure.

They are long tholly bodies, usuallly either of a conic or cylindric form, or clif refulbent the dentales in flape; and sometimes, but that very rarely, they have their smaller end bent and twifled round. They are composd within of a number of hollow compartments, each of which communicates with the next by means of a fiphunculus, which runs through the whole length, or in the manner of the thick nautiluse, or the coru ammonis. We know not thefe in their recent flate at this time, but frequently meet with them fossile in the flones brought from Sweden for pavements, and in some others.

Some authors have called thefe by the name alveoli, confounding them with the conic body found in the belemnites. See Alveolus.

Others have called them pyramidal entochi, others obelisci marisvorti alveolares; and they are the bodies defcribed by Gafner and Aldrovand, under the names of lapides cauda cancri, or concreta. Some late authors have called them also polybalaninis, and others cone-flones. Klein. de Tubul. p. 7.

Tubuli Fossiæ, the name given by authors to the cafes or tubules of sea- worms, found buried in the earth.

They are in their native flate of very various kinds, but by different accidents attending them in their accidental one, they are subject to a multitude of other appearances. They are found of very various fizes, sometimes complete, and buried in the firata of earth or flone; fometimes they are more or lefs perfect, and are immerfed in mafs of the tubes Hel- monit, or leptoria, and in this flate they make one kind of lapis furgingoides, or pipe-flone; but the most beautiful furgingoides, or pipe-flones, are the parts of the bottoms of ships, or pofts fixed in the sea, which have been pieced, in their original flate of wood, by these sea- worms, and afterwards petrifed with the cafes or tubuli of the worms remaining in them.

Of these there are many beautiful fpecimens on the shore of the island of Sheppey, and in our clay-pits about London and Richmond.

Thofe tubuli called dentaia et entalia, are not lefs frequent, and found of various kinds in the clay-pits about London and the hills of Yorkshire; but they are more frequent in fimilar places in France and Italy.

Tubuli Laeviserí, or Galáaphorí, in Anatomy, the cafes in which the milk is secreted. See Breast.

Tubuli Seminiferí, the imnumerable minute cafes compofing the body of the teitís. See Generation.

Tubuli Uriniferí, the small tubes terminating on the papilla of the kidney. See Kidney.

Tubuli Vermiculares, a name sometimes used by naturalists for certain small oblong and hollow sea-shells resembling worms.

Tubulus Marinus, or Canalis, in Natural History, the name of a genus (according to some writers) of univalve shell-fish; the characters of which are thofe: it is of an oblong figure, terminating in a point, and hollow within, in that it resembles a tube or horn. Thofe are also called by the old writers dentaia, from their refulbing the tooth of a dog. See Dentalium, Conchiology, and Shells.

It has been a common error of authors to confound under the general name of tubulus marinus, thofe shells, and thofe very different ones of the vermiculi marini, which make a number of pipes or tubes joined together; thofe, by their number and joinings, have induced a late French author to place them among the multivalve shells, while the canales are usually fingle and separate, and can have no title to any clas but the tubular univalve one. Aldrovand observes, that the
tubuli called *denatula*, and those called *antalia*, differ only in size; and he thinks they have no title to the name *conches*, since they are neither of the nature of the common bivalve nor univalve shells, such as the patella and auris marina; but this is very idle, since by this rule the finalis, and many other families, might be excluded as well as these. This author fays, in another place, that the *antale* is formed of many circumvolutions; whence he seems to have taken in the *bucina* under this name; but later writers have more nicely distinguished in these cafes. The sea-pencil is evidently of this genus, though extremely different from all the other species of it, in having its head pierced with a multitude of holes, in the manner of the head of a watering-pot. Some authors, from the figure of the shell, call this *pholus marinus*, and the French call it *le priape*. Aldrovand. de Tellac. lib. iii. p. 282.

1. T. *fallax*. Doubtful Tubulina. Perf. n. 1. Obf. Mycol. falc. 2. 28. —"Opaque, indeterminate, brownish. Receptacles combined at the top into an uniform bark."—Found, very rarely, on the trunks of trees. Perfon appears to have examined a single specimen only, and therefore knew nothing of the appearance of the plant in an early stage of growth. This specimen was about an inch long, various in breadth, of an earthy or rusty colour. The tubes were full of powder, otherwife he would have thought it rather the early flake of some *Boletus* or *Spharia*.

2. T. *fragiformis*. Strawberry Tubulina. Perf. n. 2. Obf. Mycol. falc. 2. 29. (Tubulifera arachnoidea; Jacq. Misc. Auffr. v. t. 144. t. 15. T. Ceratium; Fl. Dan. t. 659. f. 2.)—Nearly globular; first red; then brown; receptacles rather swelling upwards, dilated at the top.—Found on the trunks of trees, after heavy rains in summer, attra&ing by its likeness to a large strawberry. When arrived at maturity, it becomes opaque, of a rusty brown. The author above quoted mentions in his *Observations Mycologicae*, falc. 2, numerous fungi allied to this, partly observed by himself, and partly described by other authors, which he was doubtful whether to consider as species or varieties. His doubts seem to have been rather increased than diminished when he wrote his *Synopsis*, and therefore we cant premise to remove them. Among these obscure productions are *Sphacorpus fragiiformis*, Bulliard t. 384, and *S. cylindricus*, t. 470. f. 3, which appear to answer well to the generic character of *Tubulina*, and to be specifically dilated from *T. fragiiformis*, as represented by Jacquin. Perfon also mentions a *Reticulina multisulcia* of Sowerby's Fungi, t. 159, which is an altogether erroneous reference; nor shall we attempt to guess whether it alludes to any thing in that author's t. 399, or any other.

TUBULOSE LEAF, among Botanists. See LEAF.

TUBURBO, in Geography, a town of Africa, in the kingdom of Tunis, on the Mejerda, supposed to be the ancient Tuburbum. Mahomet, a late key of this kingdom, planted a great number and variety of fruit-trees in the neighbourhood of this town, which were ranged in so particular a method, that each species was confined to one grove, and thereby removed from all influence of another. In the adjacent valley, where the Mejerda conveys its stream, the fame curious and generous prince erected out of the ruins of a neighbouring amphitheatre, a large mally

bridge or dam, with proper sluices and flood-gates to raise the river to a convenient height for watering and refreshing these plantations. But this, which was too laudable an invention to subsist long in Barbary, was soon entirely broken down and destroyed; 16 miles W.N.W. of Tunis.

TUBUS COROLLÆ, in Botany, the inferior, more or less cylindrical, part of a monopetalous corolla, supporting the LIMBUS; see that article. The tube differs in length, in different genera or species of plants, as well as in shape. A rotate, or wheel-shaped, corolla has the tube necessarily very short, or scarcely any; a funnel-shaped has the same part elongated, and dilated upward. Sometimes the tube conceals the flanms, which are inserted either into some part of itself, or more rarely into the receptacle; sometimes, indeed very frequently, the flaments project, with the style, out of the tube. Its mouth is usually pervious; sometimes hairy; in several genera of the tribe *Asterofolius*, that part is closed by arched or converging valves, covering the anthers. The claws of the petals, in a polypetalous corolla, stand in the place of the tube of a monopetalous one, and in some inflorescences are so far connected, at an early period, as really to constitute a tube, subfrequently splitting into claws. Examples occur in the order of *Proteæceae*, which have caused some perplexity, and difference of opinion, in the characters given by different botanists of the plants of that order.

TUCABATH, in Ancient Geography, a town of Africa, in the interior of Libya, Ptolemy.

TUCANA, in Ornithology, a name given by fome to the toucan.

TUCAPEL, in Geography, mountains of Chili, S. of Concepcion. S. lat. 37° 30'.

TUCAYAN, a town on the W. coast of the island of Negros, N. lat. 11° 12'. E. long. 122° 57'.

TUCCA TERRINITHA, Shoebak, in Ancient Geography, a town in the interior of Africa, near Asfurus and S.W. of it. Ptolemy.

TUCABAR, in Geography, a town of Tunis, on the Mejerda; 24 miles W. of Tunis.

TUCABATCH, in Geography, a town of the state of Georgia; 10 miles S.W. of Oakfuskee.

TUCI, in Geography, a town of Spain, in Betica, S. of Caftulo.

TUCHAN, in Geography, a town of France, in the department of the Aude; 12 miles S. of La Graffe.

TUCHEL, a town of Prufiia, in Pomerelia; 25 miles N.W. of Culm.

TUCK of a Ship, a name given to that part of the ship where the ends of the bottom planks are collected together, immediately under the stem or counter. When this part, instead of being incurved, and forming a convex surface, assumes the shape of a vertical or oblique plane, it is said to be square; and a square tuck is accordingly terminated above by the wing-tranfom, and below, and on each fide, by the fagon-pieces. Falconer.

Tuck Rail, the rail which is wrought well with the upper fide of the wing-tranfom of ships, &c. and forms a rabet for the purpofe of caulking the butt-ends of the planks of the bottom.

TUCKABATCHEES, in Geography, a town of the Creek nation of Indians.

TUCKAHOC CREEK, a branch of the river Choptank, in Maryland.

TUCKAHOE, in Botany, the North American Indian name of a very extraordinary production, found in various parts of the United States, which appears to be a fibrousaneous fungus, nearly allied to the genus *Tuber*; see that article.
article. The Tuckahoe is found in irregular, more or less globular or oblong, lumps, from an ounce to thirty pounds in weight, having a brown corrugated bark. Its internal fibres are uniform, solid, snow-white, farinaceous, with little or no taint or flaw; and has been used by the natives as food. This production is generally found attached to the roots of some tree, especially of the genera Pinnus and Quercus, the fibres of which are interwoven with part of its texture, but in process of time are obliterated. Its growth appears to be very slow. In decay the inner fibres assume an acid flavour, and brown colour. Such are some of the particulars of the history of this fungus, for so we presume it to be, which we have received from Dr. Macbride of Charleston, South Carolina; who has lately given a more ample and detailed account of it, with specimens, to the Linnean Society of London.

TUCKAREAH, in Geography, a town of Africa, in Sahara, anciently called Tigava; 106 miles S. of Algiers.

TUCKATPOUR, a town of Hindoostan, in the circle of Ruttumpour; 18 miles S.W. of Ruttumpour.

TUCKEA, a town of Hindoostan, in Goondwana; 10 miles W. of Nagpour.

TUCKER, in Rural Economy, a term sometimes applied to a person employed in the business of fulling.

Tucker, Josiah, D.D., in Biography, a controversial writer, was the son of a small freethinker in Wales, and born in the year 1711. Having completed his education at St. John's college, Oxford, and taken orders, he served a curacy at Bristol, and was promoted by bishop Butler, who made him his chaplain, to the rectory of St. Stephen's in that city. His residence at Bristol drew his particular attention to commercial matters, in reference to which he published, about the year 1747, "A brief Essay on the Advantages and Disadvantages which respectively attend France and Great Britain with regard to Trade;" which was followed by "Reflections on the Expediency of a Law for the Naturalization of Foreign Protestants," published in two parts, 1751—2, and advocating liberal and enlarged principles. In these principles he espoused the cause of the Jews in two "Letters to a Friend concerning Naturalization," 1753. The part he took on this occasion expounded him to much obloquy, and was the occasion of his being burnt in effigy by the populace. However, in 1755 he obtained the degree of D.D., and was made a prebendary of Bristol. His activity in promoting the election of Mr. Nugent, afterwards Lord Clare, as a representative for Bristol, was recom pense in 1758 by the deanery of Gloucester. In the controversy occasioned by the petitioning clergy in 1771, he took a part, and published in 1772, "An Apology for the present Church of England, as by Law established," in which, whilst he opposed their claims, he expressed his wish for the omission of the Athanafian creed in the church service, and for excusing students of the universities upon matriculation, and graduates in lay faculties, from subscription to the articles. In the same year he published "Six Sermons," on doctrinal points that were then much agitated. In 1773 appeared his Letters to Dr. Kippis's "Vindication of the Protestant Diffenting Ministers with regard to their late Application to Parliament," which were written with moderation and candour, and in which he seems to have united the claims of the church of England respecting its own members, with liberal concessions to those who differ from it. In 1774 he published his "Four Tracts, together with Two Sermons, on Political and Commercial Subjects;" in which he unfolded his whole plan for settling the dispute with America, deemed by both the contending parties extravagant; this was "to separate entirely from the North American colonies by declaring them to be a free and independent people, over whom we lay no claim; and then by offering to guarantee this freedom and independence against all foreign invaders whatever." But he did not wish to concede the point of right in this controversy, as appeared from his publication in 1775, entitled "The respective Pleas and Arguments of the Mother Country and of the Colonies distinctly set forth; and the Impossibility of a Compromise of Differences, or a natural Concession of Rights, plainly demonstrated." Mr. Burke treated his scheme with some deference, and before he published his one of three subsequent publications on this subject, the dean became ardent and irritable in the prosecution of this dispute, and allowed himself in the abuse of the colonists, and particularly of Dr. Franklin. In 1781, apparently deviating from the principles which he had avowed in more early life, he attacked Mr. Locke and his followers on the origin, extent, and end of civil institutions, in his "Treatise concerning Civil Government." The advocates of Locke responded to him with warmth, and perhaps with some degree of altemity; but "he might confine himself (as one of his biographers says) by having his work quoted by lord Mansfield in the house of peers, with a fine eulogium on the talents of the author, whom he mentioned as a writer of the first class for sagacity and knowledge." Indulging his resentment against the Americans, and predicting consequences likely to result from their independence, which have not been verified by fact, he addressed to Mr. Necker, in 1782, a pamphlet entitled "Cui Bono? or, An Enquiry, what Benefits can arise either to the English or the Americans, the French, Spaniards, or Dutch, from the greatest Victories or Successec in the present War." In the "Preface" to this work, he undertakes to refute the opinions of the advocates for equal representation. In his subsequent commercial publications he declares himself adverse to all restrictions upon trade, and dores of leaving it to regulate itself. Having regained his rectory at Bristol to his curate, he resided at his deanery in Gloucester, and discharged the various duties of his office with exemplary fidelity. Although he was married, he left no issue. He lived to the advanced age of eighty-eight years, and died in 1799, by a paralytic stroke. Gent. Mag. Month. Rev. Gen. Biog.

Tucker, the Rev. William, one of the gentlemen of king Charles I.'s chapel, and precentor of Wittembertain Abbey, was a very judicious composer of choral music. Mr. Mafon, in speaking of the full anthem, "O give thanks unto the Lord," by this ingenious dilettante, very truly observes, that "every syllable in this composition has its full length, and each part of a sentence its proper pause; it admits no perplexing alterations or unmeaning repetitions, but proceeds in one full, yet distinct train, harmonically, yet intelligibly."

So many circumstances must concur in forming a complete musician among the lovers of the art, who have no other view in its cultivation than pure amusement, that however ardent their zeal and sublime their genius, if they have not been early initiated in the mysteries of counterpoint, and purshed its labyrinths with the perseverance of professional students, timidity, embarrassment, ignorance, and confusion, will appear in their scores at the first glance of a regular-bred composer. In general, their practice, reading of scores, experience, and application, are inferior to those of the meanest organist, or ripieno performer: disdainful to perform under parts, or to study them in the works of great masters, as soon as they know their gamut, their chief practice connotes in solos and amusing melodies; for that they remain to the end of their lives unable to count reeks, or keep
keep time, with professional firmness and accuracy; and either totally neglecting or running away too soon from plain counterpoint to florid, a want of instruction and regular study appear in the bases they put to the flightiest and most natural melodies.

TUCKER'S ISLAND, in Geography, a small island in the Pacific ocean, so called by Capt. Wilson of the Duff, from one of the crew who left the ship there. N. lat. 7° 22'. E. long. 122° 5'. Also, a small island near the coast of South Carolina. N. lat. 32° 36'. W. long. 85° 16'.

TUCKERTON, a sea-port of New Jersey, in Little Egg harbour. Also, a town of Burlington county, New Jersey; 201 miles from Washington.

TUCKET, a word used by Shakespeare in "All's well that ends well," sc. iii. 8. corrupted from toccata, Ital. a flourish.

TUCKIN, in Agriculture, the name of the fatchel that is sometimes used in setting beans in the field.

TUCKING-MILL, in Rural Economy, a name given in some places to a fulling-mill.

TUCKIT HAZAHA, in Geography, a town of Hindoostan, in Moultan; 10 miles N.W. of Toulomba.

TUCKUM, a town of the district of Courland; 33 miles E. of Goldingen.

TUCKUSH, a small island in the Mediterranean, near the coast of Algiers, opposite a town of the same name on the continent; 12 miles E. of the Cape of Iron.

TUCKWAPOR, a town of Hindoostan, in Oude; 14 miles S. of Bahraitch.

TUCKYARA, a town of Bengal; 24 miles S. of Burdwan.

TUCOPIA, an island in the Pacific ocean, discovered by Quirós in 1606. He could not find any anchoring place, but was near enough to secure with the inhabitants, who offered him a present of nuts, and a piece of cloth made of palm-leaves; and they sowed some plantations of fruit-trees.

TUCRI, a town of Naples, in the county of Molife; 13 miles E.S.E. of Molife.

TUCUBI, or TACUBIS, in Ancient Geography, a town of Spain, in Lusitania.

TUCUMAN, or TACMA, now called the Intendancy of Salta, in Geography, a province of South America, in the vice-royalty of Buenos Ayres, extending from 26° to 33° W. long., and from 22° 30' to 35° S. lat.; bounded on the N. by Chicas and Tarija, on the E. by Chaco and Yaptizlaga, on the S. by Cordova, and on the W. by the Andes, which separate it from Chili. This province is now divided into those of Salta and Cordova. Eftalla says that the province of Tucuman was the largest in America, extending from the corner called La Guadilla to the river of Quica, 380 leagues; of which 314 are fertile lands with carriage-roads, and the remaining 66 barren country with horned-places. As far as Ijuyi the temperature is benign, inclining to the warm and humid, and travellers find much convenience and abundance of provisions. The territory of Tucuman is rich and well cultivated, especially towards Chili, with some defert cantons upon the Magellanic fide. The soil is sandy, and almost without stones, but very well watered, producing plenty of cotton, wild cochineal, wax, honey, pallel for dyeing, and a variety of fruits, with roots, Indian wheat, &c. They likewise breed here vast numbers of cattle, and have plenty of deer, and other game, with lions and tigers in their woods. The sheep here are very large and strong, but their wool is fine, and the inhabitants use them also for carriage. The natives were formerly naked, but since somewhat civilized by the Spaniards, and covered with their woollen and cotton manu-

factures; they live in small villages very close to one another. Its two principal rivers are the Doke and Salado, i.e., the sweet and salt ones, besides innumerable smaller streams. In this province a kind of large crow is hunted, and an animal between a hare and rabbit. Here are said to be twelve kinds of bees, all producing honey of different qualities. The chief drink is called "Aloja," but Efafla does not mention its ingredients, but it is the chica made of maize. Throughout the province there is, as he says, no person to poor that he does not kill a cow or a helter every day for the support of his family.

In the jurisdiction of San Miguel de Tucuman (see St. Miguel) is found the tree called "Quebracho," a name derived from its extreme hardness, which breaks the axe; the outer part being white and the centre red, and the latter, after being steeped in water, becoming hard and heavy like stone. In the same province are found spiders, which weave a thread of great strength and beauty. About a league to the south of San Miguel is the salt river called Salí. This town is remarkable for the manufacture of a kind of cars, used in transporting articles of commerce. The city of Salta (see Salta) is crowded with merchants in February and March, though in the rainy season the roads are scarcely passable; the surrounding vale of Lerma produces excellent wheat, and abundant pastry, but the poor are tormented with a kind of leprosy. The graziers, who deal in mules, and the merchants, chiefly Galicians, are robust, and the women are remarkable for their beautiful complexions and flowing hair; yet the sex, after twenty-five years of age, is subject to a swelling in the throat, called "Coto," producing an effect very strange and ridiculous, and which is carefully concealed with neckcloths, but attended with no disease or abbreviation of life. This deformity seems to belong to the goitre, a disorder formerly believed to be restricted to the mountains; but as Salta is situated in a valley, it is probably produced by the water or the fogs.

TUCUMANITA, a town of South America, in the province of Tucuman; 10 miles W. of St. Miguel de Tucuman.

TUCUYO. See Tucuy.

TUCUYO, or Tucuyo, a river of Venezuela, which runs into the sea, N. lat. 10° 38'. W. long. 69° 22'.

TUDER, a town of France, in the department of the Ais. It is 11 miles S. of Rurremond.

TUDINGTON. See Tuddington.

TUDELA, a town of South America, in the kingdom of New Granada. Also, a town of Spain, in the province of Leon; 5 miles E. of Valladolid. Also, a town of Spain, in Navarre, on the Ebro; taken from the Moors in 1118; 4 miles S. of Pamplona. N. lat. 42° 11'. W. long. 1° 45'.

TUDER, Todi, in Ancient Geography, a town of Italy, in Umbria, to the S.W., among the mountains. From being a small place it became a Roman colony.

TUDERGA, in Geography, a town of Africa, in Natalia; 32 miles N.N.E. of Eski-Shehr.

TUDES, in Ancient Geography, a town of Spain, on the route from Braccara to Alcorca, between Lusia and Burdja. Anton. Itin.

TUDWAY, Dr. Thomas, in Biography, an ecclesiastical composer, educated under Dr. Blow, at the same time as Turner and Purcell. He was one of the second set of children of the chapel-royal after the Reformation. Soon after quitting the chapel-royal, he was received into the choir at Westminster as a tenor-singer. Tudway, like his fellow-disciples, endeavoured to distinguish himself early as a composer, and has entered into the Collection of Church Music which he transcribed for Lord Harley, an anthem of
his own composition, in 1675, when he was only nineteen, with six more of his early productions for the church, of which the counterpoint is but ordinary and clumsy. The words are likewise often inaccurately accented: he throws the accent of the word triumph upon the second syllable, like Handel; which, though but flighty, is, indeed, the only resemblance between them.

In 1681, at twenty-five years of age, he was admitted to the degree of bachelor of music at Cambridge. And in 1705, upon her majesty queen Anne visiting that university, he composed an anthem, "Thou, O God, hast heard my vows," which he performed as an exercise for a doctor's degree; and, after receiving that academical honour, he was appointed public professor of music in that university.

Dr. Tudway composed an anthem, "Is it true that God will dwell with men upon the earth?" on occasion of queen Anne going to St. George's chapel, at Windsor, for the first time; and, for this, and other occasional compositions, was permitted to style himself organist and composer extraordinary to that princess.

In the latter part of his life Dr. Tudway resided much in London, and was patronized by the Oxford family. The valuable scores of English church music, in fix thick volumes quarto, which are now in the British Museum, No. 7337, were transferred by himself at this time.

It is said that he used to meet Prior, sir James Thornhill, Christian the engraver, Bridgman the gardener, and other eminent artists, at lord Oxford's, once a week; and that sir James drew all their portraits with a pencil, among which is Tudway playing upon the harpsichord. Prior wrote sportive verses under these drawings, which were in the possession of Mr. Weft, the late president of the Royal Society.

Dr. Tudway's picture is in the music-school at Oxford: at Cambridge he was longer remembered as an inveterate punter, than a great musician.

In the time of the duke of Somerfet's chancellorship at Cambridge, during the discontents of several members of that university at the rigour of his government and paucity of his patronage, Tudway, himself a malcontent, and joining in the clamour, said, "the chancellor rides us all, without a bit in our mouths." Nor did the wicked fin of punning quit him even in sickness; for having been dangerously ill of a quinsey, and unable, for some time, to swallow either food or medicines; the physician who attended him, after long debates and difficulties, at length turning to Mrs. Tudway says, "Courage, madam! the doctor will get up Mayhill yet, he has been able to swallow some nourishment!" the doctor cries out, "Don't mind him, my dear, one foul word makes no fummer."

In the Annals of Queen Anne's reign, 1706, vol. v. p. 333, the following relation of Tudway's disgrace at Cambridge is unaccountable, and mentioned nowhere that we know of but in these Annals by Boyer, printed in 1707.

"About the latter end of July, the vice-chancellor of the university of Cambridge, having received information that Mr. Tudway had spoken words highly reflecting on her majesty, he convened the heads of houses at the regent's, where Mr. Tudway was cited to appear, which he did, and the words being positively proved upon oath, they all unanimously found him guilty, and proceeded to sentence, which was solemnly pronounced in the presence of the heads, and entered as an act by the public regifter, as follows: 'That Mr. Tudway be suspended of all degrees taken and to be taken; that he be deprived of his organist's place in St. Mary's church, and of his professorship of music in the university.'

"Mr. Tudway being of King's college, the provost deprived him of that place in the college, and the regifter there likewise entered his deprivation; and the butler and panter took his name off the tables in their offices. The master of Pembroke-hall, where he was also organist, in like manner deprived him of that office, and the regifter there entered it accordingly, so that he was deprived of all he held in the university of Cambridge."

We thought it probable that this sudden paroxysm of disloyalty may have been brought on by the diminution of his patron Mr. Harley; but that did not happen till a year after. In the account which Tudway gives of himself in his prefaces to the Collection of Choral Music which he made for lord Harley, he speaks with the greatest reverence of the queen, ascribes the title of her majesty's composer extraordinary, and speaks of anthems which he composed expressly for her chapels-royal at St. James's and at Windsor. It was perhaps only for the sake of an irresistible pun which offered itself in conversation, that he twitted some sentence or expression into trifon, or at least into disrepect; for he recovered all his places, had the degree of doctor in music conferred upon him when queen Anne visited Cambridge, and lived and died music-professor in that university.

TUE IRON, are cones of cast-iron with an aperture to receive the nozzles of smiths' bellows, to prevent the heat of the fire injuring them.

TUEL, in Geography, a town of France, in the department of the Ardeche; 18 miles N.W. of Viviers.

TUEL, among Sportmen, denotes the fundament of a horse, or wild beast.

TUELCAR, in Geography, a town of Hindoostan; 20 miles N.E. of Travancore.

TUELCO, fawages in the southern part of the American continent, or Terra del Fuego, refiding on the Rio Negro or Colachel, N. of the Moliches or Téuels. (See Patagonia.) The Tuelcos are a numerous tribe. They are divided into horse and foot, and are dreaded by the Indians of the Pampas, who amount to five or fix thousand souls, with about one thousand warriors; and they often join in attacks on the frontier. Their attachment to war is such, that in cafe there be no foreign enemy, one aduar or village of tents will make war against another. Their lance are generally of strong wild reeds, and they are so dangerous on horseback, that the Spanish fufleers cannot sometimes stand the charge. The head is large and makes a terrible wound, by which, as they express it, they may flee through their enemies. In these encounters the Spanish cavalry prefer the fpear, fahre, and pifhets, the carabine and cartouch-box being of little avail. The bala or bowl is of stone or metal, about the fire of those ufed in billiards; this is fixed to a fhirting about a yard long, and at the extremity, by which it is held, there are fon feathers of the American oifrich or caslowary. This fhirt is turned round the head like a fling, and with it they can frike with certainty at a funicient diftance. The bolas or bowls have been adopted by the Spanish foldiery; being two globes of fone or hard fwood fastened at the ends of a fliring, and ferving not only to enthrall the wild horfes and cattle, but alfo to annoy their ene- mies. Poniards, fabres, and cutlaffes are more ufual among these favages than the bow or the fling. During war they are all cavalry; and they chufe for their general the molt robust and valiant of their chiefs. They paint their bodies, particularly the face and hands, with black and red, not only to inspire terror, but to serve as a mark, that they may not be fingled out by the enemy. The tents or hovels of all the tribes of favages are similar, being compofed of hides of horfes, beoves, or other animals, and arranged in streets. The
The tent of the cazique is distinguished by painting and superior arrangement. The common food is the olrich and caffowary, and a kind of armadillo; but their chief regale is the flesh of the mare or foal. In cafe of urgent thirst, they will drink warm blood, which they draw from their horses. The want of food is supplied with bones, grase, and dry dung. The use of clay is universal, in making various sorts of earthenware. They eat salt with their meat roasted or boiled, and are no strangers to some preparations of milk. The Serranos or mountaineers make a paste of carobs, of which they form their bread in loaves, called patios. In Tuede, and in other southern parts, the guanoaco abounds, the flesh of which, with that of a kind of hare, forms the chief food of the Tehuels or Patagonians. But the flesh is eaten half raw. The dreadful boths hexes is a mantle, extending to the mid-leg, with an opening for the arms, and girt with a leathern belt. On horseback, the skirts are drawn together so as to form loose breeches. These clothes are sometimes made of wool, but they prefer the skins of the guanoaco, lion, and tiger; and the Patagonians use those of seals. With the feathers of the olrich they make fans, and ornaments for bridles, flaying them of various colours. These articles they exchange for tobacco, brandy, and the tea of Paraguay, which with them are articles of luxury. Hard-ware and all coarse woollies are much esteemed. The brandy they exhaust at once, making no reserve. The herb of Paraguay, after having served once, is dried, again used, and finally eaten. The tobacco is smoked in a wooden pipe. The caziques or captains have several wives, but monogamy generally prevails. Jealousy is little known, and a payment in kind is the usual penalty for adultery. Homicides and duels are frequent, and these latter open conflicts are deemed honourable; but treton and assassination are capital crimes, and the guilty are put to death with lances or wooden clubs, nor are there any churches to protect murderers. Although all are thieves, they will make war on a tribe that protects robbers. In every tented village, there is a person revered as a forcerer and physician. In the night they have no light but that of fire, which they procure by friction of hard wood. Their conflicts are so violent, that few are seen without marks of deep wounds. The dure of revenge passes from one generation to another. They celebrate their victories with dancing, singing, and drinking; painting and adorning themselves for such occasions. Their number has been greatly reduced by the small-pox. They appear to have no religion, but contemplate with reverence the fun, which they call "Antu," and the moon "Quien." The only ceremony that has any aspect of religion is, when they kill a beecie, their sprinkling some of the blood on the ground, with the formulary, "Give me to eat, me, and my people." They think that the moon confers strength and valour; and when the new moon appears, they present their infants, and say "make them strong." They also pray to Quien for courage and strength to avenge injuries, and destroy their enemies. Ineffecual attempts have been made by popish missionaires for their conversion. The missionaires were slain and the few Christians dispersed. Such is Ellalla's account of these savages.

TUILLA, La., a town of France, in the department of the Dord; 16 miles W. of Aosta.

TVER, a town of Russia, and capital of a government, at the conflux of the Tvertza and Volga. It is the seat of an archibishop, and, according to Bulching, contains twenty churches and convents. Tver, from a small fortres, became a town, and increased in population and wealth to a great a degree, as to become the metropolis of an independ-
matter in solution, or mechanically suspended. Tufa is also formed by the concretion of loose volcanic dust or cinders cemented by water: and also by the concretion of mud thrown out of volcanoes. The disintegration and sub-sequent concretion of basaltic rocks forms a third kind of tufa, which the German geologists call trup-tuff.

Calcareous tufa is formed in large quantities in many lime-flone districts. The waters which issue from calcareous rocks rise to the surface impregnated with a considerable quantity of carbonate of lime. On exposure to the air and light, they deposit their contents on whatever substance is presented to them, and in the beds of rivulets form solid incrustations, sometimes of great extent, and many yards in thickness. The stone thus deposited is always more or less porous or vesicular, and contains portions of plants and fresh-water shells which it has enveloped. This stone hardens by exposure to the air, and is frequently employed in architecture. It is not a little remarkable, that St. Peter's church, and some of the grandest works of ancient and modern architecture at Rome, are formed of a species of calcareous tufa, called by the Italians travertina. In the vicinity of Stroudwater, in Gloucestershire, many of the springs that issue from the feet of the Cotswold hills make large deposits of calcareous tufa. At one station, called the Rock-mill, a bed of this stone, more than thirty feet in thickness, has been worked formerly for building, as appears from some of the oldest edifices in the neighbourhood, which proves the hardnefs and durability of this stone. In Derbyshire, and all the calcareous districts in England, beds of tufa are formed by similar depofitions. Beds of tufa are very common among the mountains which terminate the high valleys of the Alps, and there are promontories of calcareous tufa in the valleys of Switzerland. It was generally supposed that the particles of lime-flone were held in solution by carbonic acid in the water, and that the evaporation of this acid, after exposure to the air, occasioned the depositioh of the calcareous particles. Dr. Kidd, of Oxford, has made some experiments on the solvent power of simple water on carbonate of lime, which he finds to be much greater than was generally supposed. If, says he, half an ounce of distilled water be agitated for a short time in contact with pulverized carbonate of lime, it will be found, on the addition of oxalate of ammonia, that the water will be rendered turbid. It appears, therefore, that when a spring, charged with as much calcareous matter as it is capable of holding in solution, has issued from beneath the earth, the requisite quantity has been diminished by evaporation, the particles of calcareous matter are liberated and deposited.

Calcareous tufa forms so rapidly in some situations, as entirely to close up the passages in canals and aqueducts through which calcareous waters flow. Many hot springs deposit tufa in abundance: the heat appears to affiit the solvent power of water, and to accelerate the precipitation of its contents by a more rapid evaporation from the surface.

The travertine, or tufa, is the most remarkable of all the calcareous tufas, as it has been employed for the construction of some of the prouder monuments of architectural genius in ancient and modern times. Of this stone, Breiflak, an Italian mineralogist, gives the following interesting description.

"The Anio, or Tivorie, which depends from the Apenines of Visuviano and Subico to the call of Rome, crofhes Tivoli before reaching the plain where it unites with the Tiber. All the land through which the Anio passes in Tivoli, whether near the great cascade or the smaller ones, is filled with mafles of a calcareous flone, produced by the deposition of its waters. Sometimes a piece of rufh or reod, or other vegetable matter, is the first point to which the calcareous earth begins to attach itſ elf. It generally depofes in concentric layers, and has the hardneſs and fibrous tifue of alabater. These layers are nevertheleſs separated by a bed of calcareous earth, friable, yellowish, and very fine. At the foot of the mountain of Tivoli, where the Anio enters the plain which extends to Rome, are the quarries of travertine. This calcareous rock is depofed in horizontal beds: its colour is yellowish-white, its grain earthy, fracture uneven, and its hardneſs far furpaffes that of thoſe calcareous mafles produced by the Anio in the neighbourhood of Tivoli. Cavities, where the calcareous flubinance has afsumed a fpary grain and italatich form, are common in travertine. Sometimes thefes cavities have been line filled by a calcareous italatich, whiter, of a finer grain, and harder. This is the origin of thoſe white flones, the regularity of which has caused them to be miſtaken for marine bodies enveloped in its pale. Travertine contains no remains of marine flubinaces, but sometimes it affords fragments of vegetables. It is not doubted but travertine owes its origin to the depofitions of the Anio; depofitions which in the plain may have formed a more solid and compact rock; because its current was lefs rapid, and perhaps its waters more ftagnant in ſeveral places. Not far from the quarry of travertine is the Solfataræ, fo called on account of the great heat of its waters, which abond in sulphuric hydrogen gas, and form a confiderable fediment of calcareous matter. A cardinal d'Este caufed the canal to be dug which conveys the waters of the lake to the Anio. The calcareous depofitions are there fo abundant, that if every three years it was not cleaned out, it would be closed up, notwithstanding its depth and breadth. The water which runs in the canal, on meeting with the bits of rufh or other bodies, covers them with a white calcareous crust, two or three lines in thickness. These incrustations are known by the name of confus of Tivoli. Before this paſfage was opened, the overflowings to which the lake is ſubject were often fo confiderable, that the water spread over the neighbouring grounds, and formed on their ſurface a flothy crust. The waters of the lake were charged with calcareous earth, uniting with thoſe of the Anio in the floods which their union might produce, have themselves contributed to the formation of travertine. I do not think that the Anio alone would have been capable of forming the quantity which is found in this rock."

"Independent of the ſeveral quarries worked by the ancients, there are besides others of ſuch vast extent, that they may supply the demands of many ages. The lake of Solfataræ seems to have greatly aflifted in the formation of this rock. Its water being charged with gaz, explains the great number of hollows which travertine prefents. It proves, that when the rock hardened, a gaz has at the fame time efcape in ſeveral places, which has prevented the approximation of its parts, which were ſtill soft. As often as the interior of a mafs of rocks prefents cavities without any indication of foreign ſubstances which migbt have oppoſed the union of its parts, I conceive their origin may be attributed to the ecape of gaz at the moment when the ſubstance was palling from a ſlate of softneſs to solidity, by cooling or drying. From what I have juft ſewn, it follows that the travertine or rock of Tiber or of Tivoli is a carbonate of lime, formed by the depofitions of the Anio and the Solfataræ of Tivoli. The Roman artificiels give the name of travertine only to the flone taken from the quarry ſituated at the foot of the mountain of Tivoli. The lithologiſts, leſs ſlavels
TUFE, in Geography. See TUFAN.

TUFARA, a town of Naples, in the province of Capitanata; 5 miles W. of Volturna.

TUFECI, a body of the Ipahis, or orfeis, in the service of the grand signor.

TUFÉ, in Geography, a town of France, in the department of the Sarthe; 7 miles S.W. of La Ferté-Bernard.

TUFEN, a town of Switzerland, in the canton of Zurich; 13 miles N. of Zurich.

TUFFENBACH, a town of the duchy of Stiria; 9 miles S. of Judenburg.

TUFFO, in Botany, a name given by the people of Guinea to a plant common in that country, and used in decoction to wash boys with. It is of the sun-flower kind, and is called by Petiver, *flos folium Guineenfis folio fucro furo minor*. It much resembles some of the American sunflowers. Phil. Trans. No. 232.

TUFFOA, in Geography, a town of Africa, on the Slave Coast; 40 miles W. of Affom.

TUFFOONS, in Meteorology. See Tonquin.

TUFT, in Botany and Vegetable Physiology, technically implies a head of flowers, *capitulum*, of which each individual is not fertile, but elevated on either a simple or subdivided partial falk, though all together composing a dense roundish mass. Perhaps tuft would be better retained in English as synonymous to *foliculus*, in which sense it is often practically used, for any small number of flowers, on short aggregate or subdivided falks, springing from the bofoms of leaves, or the divisions of a panicule or corymb. In like manner this term is applied, with more laxity, to little bundles of leaves, hairs, &c. on different occasions.

TUFTED DUCK, in Ornithology. See Tufted Duck, or Fuligula under Duck.

TUFTED Vetch, in Agriculture, a term commonly applied to a perennial fort of this plant, which is highly deserving of cultivation by the farmer, for either meadow or paffure land. It is frequently found mixed with the other grasses, in rather moist ground. See Vetch, and Vicia Cracca.

TUFONBOROUGH, in Geography, a town of New Hampshire, on the north side of Winnipissogee lake; 32 miles N. Concord.

TUG, Bayin, in Agriculture, a sort of carriage used in some districts for loading bayins or faggots, and sometimes other kinds of feld-goods. It is made as to be capable of carrying a hundred and fifty faggots, each four feet in length, and three feet in girth, without being over top-heavy, so as to be liable to turn over in bad roads. It is much used in the weald of Kent, and some other counties.

TUGELOO, in Geography, a town of the plate of Georgia; 95 miles N.W. of Augusta. N. lat. 34° 36'. W. long. 83° 21'.—Allo, a river of the plate of Georgia, one of the branches of the river Savannah, which joins the Kewee; 28 miles N.W. of Petersburg.

TUGGA, a town of Tunis; 20 miles S.W. of Carthage.

TUGGALA, or TEGLA, a town of Africa, in Kordofan; 150 miles W.S.W. of Sennaar.

TUGGEN, a town of Switzerland, in the canton of Glarus; 5 miles S.W. of Utznach.

TUGGURT, a town of Africa, in the kingdom of Tunis; 60 miles S.W. of Tunis.—Allo, a town of Africa, in Nigritia, capital of a district called Wardage; 260 miles N.E. of Tombuctoo. N. lat. 20° 30'. E. long. 6°.
TUGGURT, or TOCORT, a town of Algiers. It was formerly under the protection of the Turks, and paid a tripling acknowledgment. The inhabitants being disgruntled with the conduct of their masters, revolted; but were reduced to obedience, the town taken, and great numbers of them put to the sword; 240 miles S.S.E. of Algiers. N. lat. 32° 40'. E. long. 6° 52'.

TUGIA, in Ancient Geography, a town of Spain, upon the route from Cañuto to Malaca, between Cañuto and Traxium. Anton. Itin.

TUGMA, a town of India, on the other side of the Ganges and near it, with the title of Metropolis, according to Ptolemy.

TUGPINS, in Artillery, are the iron pins which pass through the fore-ends of the shafts of the army carts, to fasten the draught chains for the fore-horses.

TUGUESA, in Geography, a town of South America, in the province of Darien; 50 miles N.E. of St. Maria.

TUGULIAN, a town of Ruffia, near the straits which separate the continent of Asia from America. N. lat. 65° 54'. E. long. 189° 14'.

TUGUS, in Botany, the name of a sweet aromatic plant, growing up sometimes to eight or nine cubits, much esteemed in the eastern parts of the world, and supposed by father Camelli, who very skilfully compared it with the accounts given by Dioscorides and the ancients of their anomum, to be that very plant. The clustered manner of growing of the fruit, together with its oblong shape, and the aromatic taste of the seeds, seem greatly to countenance this opinion.

Each fruit of the tugus contains five or seven seeds; these are of an oblong figure, of a reddish colour, and of an agreeable aromatic taste, but not too acrid. They are much sought after by birds, insects, and field-mice.

The natives seem as fond of these as the ancients were of the anomum; and the young women string them on threads, and wear them as bracelets; sometimes they make the bracelets of the seeds alone; but more usually they string them alternately with pearls, and pieces of red coral: these bracelets they call carops, as well as the fruit itself.

They are suppos'd, when worn by way of necklace, to keep off the effects of a bad air, and to preserve them from the bites of serpents, or the centipes. If not a preservative, they are, however, found, upon experience, to be a very good remedy in the last case, the common application for the bite of this animal being some of the seeds of the tugus chewed in the mouth to a sort of paste.

The chaffer of fruit of the tugus, or true anomum, when newly formed and unripe, somewhat resembles the pseudo-anomum of Garcins; but this likewise wears off as they ripen. For Camelli's accurate description of this plant, illustrated by a figure, see Phil. Trans. No. 248. p. 2.

TUGUZAK, in Geography, a river of Ruffia, which runs into the Uvelka, 12 miles E. of Troitz, in the government of Upha.

TUGWELL PLOUGH, in Agriculture, a light, easy-going, well-contrived implement of this kind, invented by a person of that name. It performs the work well, but not deeply, consequently is improper for weeding lands. It is sometimes termed the Gloucester plough. See Plough.

TUHERE, in Geography, a town of Brasil; 45 miles E. of Paru.

TUHLOIS, a town of Sweden, in Tavalland; 15 miles N.E. of Tavallhus.

TUI, a river of South America, which runs into the Caribbean sea, N. lat. 10° 30'. W. long. 67° 20'.

'Tui, in Ornithology, a name by which some call the parrot. See Psittacus.

The word is originally Brazilian; and the names of several of the Brazilian species of this bird, described by Marcgrave, have the word tui as a part of them; as the tuiete, the tuibara, the tuirica, and the tuinaputejuba. See Tuiete, &c.

TUIAPUTEJUBA, the name of a Brazilian species of parroquet, all over of a green colour, but in different shades, very deep on the wings, very pale, and somewhat yellowish on the belly, and of a faint colour all over the rest of the body; its tail is very long; it is about the size of a fawn; its eyes are large and black, and have a circle of yellowish-green feathers round them, and over the beak, which is black and crooked; and on his head he has one spot of gold-yellow feathers. See Psittacus Pertinax.

TUICEA, in Geography. See Pirom.

TUIETE, in Ornithology, the name of a Brazilian species of parroquet, of the size of a lark, and all over of a pale green colour, variegated with blue; the origin of its wings is blue, as are also the ends of the wing-feathers, so that when the bird sits still, there is, as it were, a blue line feen running down each side; on its rump there is also a blue spot; its tail is but short; its beak is small, crooked, and of a pale red; and its legs and feet grey. See Psittacus Pafserinus.

TUILERIE, or TILERY, French; formed from tuile, tile, a tile-work; a large building, with a drying-place, covered at top, but furnished with apertures on all sides, through which the wind having admittance, dries the tiles, bricks, &c. which the work would crack, before they be put in the kiln.

The garden of the Louvre is called the Tuileries, as being a place where tiles were anciently made, &c. But the term Tuileries does not only include the garden, but also a magnificent palace, whole front takes up the whole length of the garden.

The palace of the Tuileries is joined to the Louvre by a large gallery, which runs along the banks of the river Seine, and has its prospects on it.

The Tuileries was begun in 1564, by Catherine de Medicis, wife of Henry II., in the time of her regency; it was finished by Henry IV. and magnificently adorned by Louis XIV. The garden of the Tuileries was much improved by Louis XIII.

TUIPARA. See Taipara, and Psittacus Tuipara-Tuirobius, in Ancient Geography, a river of Albion, on the western side, which lies along the Irish and Vrgian seas; universally agreed to be the river Tyvi.

TUIS, in Geography, a town of Italy, in Friuli; 10 miles W. of Udina.

TUISCO, or TUSTON, in Mythology, a name given by the ancient Germans to a celebrated person, whom they regarded, by the descendants of his son Man or Mannus, as the founder of their nation, and whom they represented to be the son of the earth, because they were ignorant of his origin. He gave them laws, polished them, established religious ceremonies among them, and obtained such a high degree of reputation, that after his death they ranked him among the gods. One of the principal ceremonies of his worship consisted in finging songs in praise of him. These fongs, according to Tacitus, were very ancient: "Celebrant," says he speaking of the Germans, "carminibus antiquis Tuiftoncm Deum, terra editum, et filium Mannum, origi-
hem gentis conditoresque." Caesar thought that Pluto was
honoured under this appellation. Accordingly he says
(De Bell. Gall. 1. 6.) "the Druids report that the Gauls
are come from Dis or Pluto, who after his death was wor-
shipped by both nations as their father and founder, by the
Gauls under the name of Pluto, and by the Germans under
that of Tuilton, and both of them erected statues to him in
the woods."

Some have ascribed the origin of the name Tuesday to
this deity. See Week.

TUITIRICA, in Ornithology, the name of a Brazilian
parroquet, which is a little larger than the common kind;
all over of a fine beautiful green, but deeper on the back
and wings than elsewhere; its beak is very hooked, and of
a pale red; its eyes black, and its feet blue; its tail is but
a little longer than the wings when closed. This is a spe-
cies much esteemed in the Brazils, as it easily learns to
talk, and forms so tame as to eat out of any one's mouth. See
PSITTACUS Tiriaca.

TUK, in Geography, a town of Charafin; 18 miles N.
of Urghen. — Allo, a town of Egypt, on the left bank of
the Nile; 6 miles N. of Nekkade.

Tuk el Effrat, a town of Egypt; 5 miles N. of
Gizeh.

TUKERA, a town of Hindoostan, in Oude; 14 miles
N. of Lucknow.

TUKKIKARI, a town on the eait side of the gulf
of Bothnia. N. lat. 65° 26'. E. long. 25° 12'.

TULKHTAR, an island in the North sea, near the
east of East Greenland. N. lat. 61°. W. long. 46° 26'.

TUUKOOR, a town of Abyssinia; 20 miles W. of
Tcherkin.

TUKURN, a town of the duchy of Courland; 32
miles E.S.E. of Goldingen.

TUL, a town of Grand Bucharia; 36 miles S.E. of
Anderah.

TULA, a city of Russia, and capital of a government,
on the Upha. According to Butchling, it contains 144
churches and convents. Near it are some iron mines, and in
the city are manufactures of fire-arms, all sorts of cutlery and
other works in polished steel, and leather. The number of
merchants, including shop-keepers, is estimated at 4,000,
some of whom are very rich. The number of inhabitants is
estimated at 30,000: the population is increasing, and be-
ides wooden buildings there are many of stone; 112 miles
S. of Moscow. N. lat. 53° 45'. E. long. 37° 30'.
—Allo, a town of Mexico Proper; 40 miles N. of Mexico.
—Allo, a river of Mexico, which runs into lake Chapala,
near Zamora.

TULACUM, in Natural History, a name given by the
people of the East Indies to a species of the yellow orpi-
ment, of the coarser kind, variegated with red. They
prepare this by several calcinations, and then give it inter-
ally in fevers, and many other disorders, relieving it a
fort of panacea. They say that gold may be extracted
from it, which is not improbable; for it is well known,
that some of the Roman emperors did actually procure
gold from one of the other kinds of orpinent, which is
now found at Goofelear in Saxony.

TULAH, in Geography, a town of Hindoostan, in
Bengal; 31 miles E. of Dacca.

TULBAGHA, in Botany, so named by Linnæus in
honour of the Dutch governor Tulbagh, long resident at
the Cape of Good Hope, who sent numerous plants from
that country to professor Burmann, and furnished Linnæus
with several of its insects, particularly a fine species of
Papilio, which is called Tulbagha, being one of the tribe of
Nymphales; see Syll. Nat. ed. 12. v. 2. 775. Linn. Mant. 2.
Lamarck Ill. tr. 1. 243. Gærtn. t. 16.—Clars and order,
Hexandria Monogynia. Nat. Ord. Spathaceae, Linn. Narcrie,
Jaff.

Gen. Ch. corrected from the Linnæan MSS. Cal.
Sheath of two oblong membranous valves, containing many
flaked flowers. Cor. of one petal, inferior, falver-shaped;
tube cylindrical; limb in fix equal, lanceolate, acute,
spreading segments, shorter than the tube. Nectary of three,
distinct or combined, cloven, acute, equal, feby leaves,
crowning the tube. Stam. Filaments fix, very short, three
in the throat of the tube, three lower down; anthers heart-
shaped, acute. Pist. Germin superior, ovate; style cylin-
drical, much shorter than the tube; stigma turbinate, de-
prefed. Peric. Capsule ovate, with three angles, three
intermediate furrows, three cells, and three emarginate
valves. Seeds few, oblong, obtuse, triangular, comprelfed,
corrugated.

Eff. Ch. Corolla falver-shaped; limb in fix equal seg-
ments. Nectary of three cloven fleses, crowning the tube.
Stamens three in the throat, three within the tube. Cap-
ule superior, of three cells and three valves. Seeds comprelfed.

Mag. t. 836. (T. capensis; Linn. Mant. 2. 223. Jacq.
Hort. Vind. v. 2. 52. t. 115.)—Flowers drooping. Nect-
ary of one leaf, in fix segments, as long as the limb of the
corolla.—Native of low fandy spots, near the town, at the
Cape of Good Hope, flowering about July, and called by the
Dutch colonists Wilde Knoplock, or Wild Garlick. It is
said to be used for disorders of the breath, fewed in milk;
but whether internally or externally, is not recorded. This
species was sent to Kew by Mr. Mallon, in 1774. Jacquin
had it a few years earlier. Root tuberous, with numerous
feby fibres. Leaves radical, erect, numerous, two-ranked,
linear, blotifer, channelled; fheathing at the base. Stalk
solitary, about a foot and a half or two feet high, roundih,
simple, bearing a fcoo embel of from ten to fifteen spreading
or drooping flowers, whose partial falks are near an
inch and a half long. Each flower is rather smaller than a
Harebell, oppressively sweet in an evening. Corolla green
or slightly glauccous. Nectary purpliff-brown. Seeds black.
The whole plant, when ever so slightly bruised, exhalas
a rank smell of garlick, full perceptible in the old dried
specimens of the Linnæan herbarium, whenever they are
touched or moved.

excluding the synonyms. Wildl. n. 2. Ait. n. 2. Thunb.
Prodr. 60.—Flowers erect. Nectary of three distinct
cloven leaves, half as long as the limb of the corolla.—
Native of the Cape of Good Hope, from whence it was
sent by Mr. Mallon to Kew garden in 1795. A smaller
plant than the foregoing, with much narrower leaves.
Umbel, in our only specimen, of seven flowers, whose
corolla is purple, or crinum. Of the colour of the ne-
carry we cannot judge, but its length is about half that of
the segments of the petal.

There can scarcely be a greater example of confusion
than the history of these two plants in the Supplementum
of Linnæus, nor could it be unravelled without the original
specimens. If in the character and description of the fright
we read folia subincarnata, instead of subflabellata, it may
be intelligible. The root moreover, in one specimen, seems
bulbous. All the rest answers tolerably well. In the second
second species, the *leaves* are pericly linear; the *root* by no means fleshy, except its fibres, being exactly like the former; to which the synonyms, even of Lamark himself, undoubtedly belong. A figure of *T. capensis* is much wanted. The plant is now to flower at Kew in April.

3. *T. hypopoda*. Short crowned Green Tulbagia.—Flowers drooping. *Nectary* very short and obtuse. Segments of the limb of the corolla taper-pointed.—This hitherto nondescript flower was planted in 1792, in the Grove of Meffrs. Lee and Kennedy, of Hammeirmith, who received the root from Holland. There can be little doubt of its having been brought to that country from the Cape of Good Hope. The *leaves* are linear and very narrow, about one-fourth the breadth of *T. alliacea*. The *inflorescence*, as well as the posture and general aspect of the flowers, most resemble that species. The *corolla* is green, but its segments more taper-pointed, and full as long as the tube; while the *nectary* is extremely short and blunt, rising but little above the mouth of the tube, and confiding, if we mistake not, of three undivided lobes.—Mr. Sowerby made a drawing of this species at the period above-mentioned, which, though now mislaid, may one day probably be given to the public.

TULBAGIA, in Gardening, contains plants of the tender, herbaceous, exotic kind, among which the species cultivated are, the alliacea or garlic tulbagia (*T. alliacea*); and the cephaceous or onion tulbagia (*T. cepacea*).

Method of Culture.—In each of these sorts, the young plants may be increased by sowings the seeds, sifting the branches, and offsets from the roots.

The seeds should be sown while fresh in pots filled with light mould, and be plunged into a tan hot-bed any time in the autumn or spring feasons, when they will soon begin to grow. And the slips and offsets may be planted and managed in the same way. The young plants in all the cafes must constantly remain in the stove, and have water occasionally given them.

Both these plants afford an agreeable diversity in flower collections.

TULBING, in Geography, a town of Autria; 4 miles S.S.E. of Tulln.

TULCZA, a town of European Turkey, in Bulgaria, on the south side of the Danube, opposite Ismail. In the year 1771, this town was taken by the Russians, and again in 1792.

TULCZIN, a town of Russian Poland; 12 miles S.W. of Bracjow.

TULEBRAS, a town of Spain, in Navarre, on the Quejios; 7 miles from Tudela.

TULIAN, a town of South America, in the province of Cordova; 110 miles N.W. of Cordova.

Gen. Ch. Cal. none. Cor. bell-shaped, inferior, of six ovate-oblong, concave, erect, deciduous petals. Stan. Filaments fix,awl-shaped, much shorter than the corolla, taper-pointed; anthers oblong, quadrangular, erect, feratice, flatish. Pet. Germen superior, large, oblong, bluntly triangular; style none; stigma with three prominent angles, or three divided lobes, permanent. Peric. Capsule triangular, somewhat elliptical, of three cells, and three ovate valves fringed towards the edges. Seeds very numerous, flat, femicircular, lying horizontally over each other, in a double row, with scales of the same shape (or barren seeds) between.

1. *T. sylvestris*. Wild Yellow Tulip. Linn. Sp. Pl. 438. Wildl. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 63. Fl. Dan. t. 375. Curt. Mag. t. t. 1202. Redout. Liliac. t. 175. (T. bononiensis; Gen. Em. 178.)—Flower foliary, somewhat drooping. Leaves lanceolate. Stigma triangular, abrupt, slightly three-crested. Stamens hairy at the base. Petals acute, hairy at the tip.—Native of Sweden, England, Bohemia, Germany, Switzerland, and France, flowering in April. Root an ovate bulb, flattish at one side, prominent at the other. Stem quite simple, erect, round, smooth, twelve or eighteen inches high; leafy in the middle; tapering at the base. *Leaves* about three, alternate, lanceolate, acute, keeled, entire, smooth, somewhat glaucous; the uppermost linear and much the narrower. *Flower* drooping, till it is fully expanded, of a fine golden yellow, sweet-scented; the three outermost petals greenish at the back; all of them elliptical, acute at each end, and tipped with a little white wool at the summit; three innermost fringed with similar wool at the base. *Stamens* yellow; their filaments densely woolly at the bottom; anthers linear-oblong. *Germen* pale yellow or greenish, crowned with a triangular, abrupt, not dilated *stigma*, gradually splitting into three small notches, slightly downy at the top. The Early Yellow Tulip of the gardens, which is figured in the plates of Redouté and Curt. Mag. cited above, can hardly be distinguished from our wild kind, except being larger, with a rather more decidedly three-lobed woolly *stigma*. Our Bohemian wild specimens are intermediate between the two.

2. *T. Celsiana*. Small Yellow Tulip. Redout. Liliac. t. 38. Ait. Epit. 375. Curt. Mag. t. 171, erroneously named *Melan-thiun uniflorum*. (T. biflora; Dom. Cant. ed. 5. 1752.) *T. perifca minima*; Rith. Elyt. v. 2. *T. l. f. s.*—Flower mostly foliary, erect.—Leaves lanceolate. Stigma triangular, with three short, rounded, downy lobes. Stamens slightly hairy above their base. Petals smooth at the tip.—Native of the south of Europe, and of the banks of the Volga. We have known this species for above twenty-five years in Chelsea garden, where it was cultivated by the late Mr. Fairbairn, in pots, amongst alpine plants, protected by a frame in winter, and flowered about May. So little was it understood, that the able writer on this tribe of plants in Curtis's Magazine originally mistook this Tulip for *Melan-thiun uniflorum*; an error corrected at t. 1135 of the same work. It is very nearly allied to the *sylvestris*, but not half so large, and the flower is tinged with red externally. The three innermost *petals* are slightly fringed at the lower part, but all fix are quite smooth at the extremity. The *tbrons* are smooth at the base, though they bear a tuft of hairs a little way above it. Anthers shorter, and more elliptical, than in *T. syl vestris*. Stigma more decidedly three-lobed, rounded, and downy. Capule elliptical. Very rarely there are two flowers on a stem. They have no scent. Each *petal* has sometimes, not always, a green keel.

3. *T.
TULIPA.

3. *T. biflora.* Two-flowered Yellow Tulip. Pallas l. 1. v. 3. 727. t. D. f. 3. Linn. Suppl. 196. Wildl. n. 2.—Stem two or three-flowered, with two spreading lanceolate leaves. Stigma triangular, abrupt, downy, scarcely notched. Petals widely spreading, hairy, like the stamens, above their base; smooth at the tip.—Native of falk deserts about the river Wolga, in a stiff clay soil, along with the lai, but flowering a few days earlier, and of much shorter duration. This is scarcely half the size of *T. Celifana,* of which a two-flowered specimen has sometimes been taken for it. The more simple *fligma,* more elliptical and expanded petals, green at the back, and more oblong *anthers,* are abundantly different from that species. From the *flavoferis* the present is still more unlike, as to size, smoothness of the tips of its petals, and their flat spreading position, to say nothing of an orange spot at their base. The foliage too is full by Pallas to be more glaucous and succulent. The flowers vary rarely to one or three, and are fragrant.

4. *T. Sibthorpiana.* Yellow Greek Tulip. Sm. Prodr. Fl. Grec. Bith. v. 1. 229. Fl. Grec. t. 329, unpubl.—Stem single-flowered, smooth. Flower drooping. Petals obtuse. Stigma club-shaped. Filaments hairy all over.—First observed by the late professor Sibthorp, near the ancient Creifa, now Porto Cavalieri, in Afa Minor; and afterwars, as Mr. Hawkins informs us, on a small rocky eminence near Navarissi, in the Peloponnesus. The root is a white, roundish, depressed bulb, feebly an inch in diameter, surrounded by numerous lateral offsets. Stem a span high, bearing two alternate erect smooth leaves, of which the lowest is largest and most ovate. Flower entirely yellow, pendulous, an inch long. Petals apparently smooth in every part. *Stamen* whitish as well as the *filis.* *Anthers* linear, somewhat curved, as long as the filis. Stigma covered with a brown, black, yellow-edged spot at its base. *Stigma* like the following.

5. *T. Chlafiana.* Red and White Italian Tulip. Redout. Lilac. q. 37. Ait. Epit. 375. Curt. Mag. t. 1390. Sm. Prodr. Fl. Grec. Bith. v. 1. 229. Fl. Grec. t. 329, unpubl.—(T. perica praecox; Cluf. Cur. Polt. 9, with a figure. T. perica, flore rubro, oris albidos, elegans; Ger. Em. 142. T. perica; Park. Parad. 52. t. 53. f. 6. T. variagata perica; Rudd. Elyt. v. 2. 111. f. 7.)—Stem single-flowered, smooth. Flower erect. Petals acute, smooth. Leaves linear-lanceolate. Native of Italy, Sicily, and Periza, flowering in March. About the fize of *T. fyl-voferis,* but the stem bears four or five leaves, gradually smaller and narrower upwards, most glaucous beneath, smooth, somewhat undulate, at the lower one all taper-pointed. The three inner petals are white on both sides, sometimes blunthit; three outer rather larger, acute, white or bluish-coloured within, crimson at the back, with white edges, and a green tip; all of them marked at the base internally with a dark-violet spot, and all quite smooth in every part, as are the violet-coloured *flamae,* and green *filis.* The *fligma* consists of three rounded, compressed lobes, each marked with a downy furrow, like the Garden Tulip hereafter described.

6. *T. flavoferis.* Early Dwarf Tulip. Roth. Catal. v. 1. 45. Curt. Mag. t. 839. Wildl. n. 2. Ait. n. 2. Redout. Lilac. t. 111. (T. Pumilio; Lob. le. 127. Ger. Em. 142. T. Pumilio latifolia; Rudd. Elyt. v. 2. 109. f. 2.)—Stem single-flowered, downy. Flower erect. Leaves ovato-lanceolate; downy above. Petals and filaments smooth.—Supposed to be a native of the souther of Europe. Commonly cultivated in Holland, by the name of *Deu Pan Thol,* from whence the best roots are brought to us. They flower in the open ground in March or April, but in a room, whether in water, sand, or earth, about January. The whole plant is a dwarf stature, and glaucous hue. Flower broad-bellshaped, sweet-scented. Petals scarlet, edged with yellow, more or less acute. *Stigma* like the lai, but rather larger.

7. *T. Oculis folis.* Agen Tulip. "St. Amans Rec. Soc. d’Agr. d’Agen, v. 1. 75." Redout. Lilac. t. 219. Ker in Edw. Bot. Regist. t. 204. (T. bolonifrismo, five bombycina, florae rubro, major; Park. Parad. 51. t. 53. f. 1.)—Stem single-flowered, smooth, as well as the petals and filaments. Flower erect. Leaves ovato-lanceolate, finely fringed.—Found about Agen, in France, and several places in the southern part of that kingdom, flowering in April, and lately imported into England, by Meffrs. Whiteley and Co. of Fulham. This differs from the lai in the particulars contained in our specific character, and more nearly approaches the following. The coat of the bulb is said to be internally woolly. Leaves broad, slightly glaucous. Flower large and bell-shaped, of a fine scarlet red, each petal marked with a broad, black, yellow-edged spot at its base. *Stigma* like the following.

8. *T. Gefzeriana.* Common Garden Tulip. Linn. Sp. Pl. 438. Wildl. n. 3. Ait. n. 3. Curt. Mag. t. 1135. "Sowerb. Fl. Luxur. t. 5. 6. 11. 17." (Tulipa; Rudd. Elyt. v. 2. 102—108.)—Stem single-flowered, smooth, as well as the petals and filaments. Flower erect. Leaves ovato-lanceolate, glaucous, smooth. Lobes of the *fligma* decurrent, deeply divided.—Native of the country bordering on mount Caucasus, where it flowers in April, and from whence Dr. Fletcher has sent us a wild specimen. Conrad Gesner reports, that it was brought from Cappadocia into the European gardens, in 1559. Nothing is now more common or more famous, particularly the many varieties in form and colour, which florists, especially in Holland, have so much cultivated, and in some sales do highly prized. The old botanical writers, in their wooden cuts, represent many of thefe, and almost all the supposed species in Bauhin’s *Patas,* are really, as Linnaeus indicates, mere varieties. In a wild state, the *petals* are crimson, yellowish at the base, about an inch and a half long; by cultivation they increase in size, become streaked in colour, and sometimes assume a jagged and spurred appearance, with every variety of scarlet, yellow, purple, and even green, in their colouring. This we first called the Parrot Tulip, a name now generally adopted. It is Rudbeck’s *T. flava luteo rubra varigata, petalis laciniosi.* A yellow Tulip, the blunt points of whole petals are somewhat recurved, and whose whole flower is of a handsome ovate figure, seems to us possibly a distinct species, but this must be decided by cultivation from seed.

Tulipa, in Gardening, furnishes plants of the bulbous-rooted, flowery, perennial kind, among which the species cultivated are the Gefzeria, Turkey, Cappadocia or common garden tulip (*T. Gefzeriana*); and the wild or yellow tulip (*T. fylvoferis*).

The firl is distinguished from the other fort, according to Martyn, by its subfufent scape, spreading (wheat-yellow) corolla, the caltines of its flowering, and the smallnes of its fize.

And in regard to the varieties, the editor of Miller’s Dictionary observes, that the old authors divided tulips into praecox or early-flowers, and fercinca or late-flowers, with an intermediate division of dubie mutis, doubtful or middle-flowers, which flowered between the two others, and for the
the most part rather belonged to the late-blowers. Modern florists, lie afferts, have almost neglected the early-blowers. The first fort, according to him, are not near so fair, nor do they rise half so high as the late ones; they are chiefly valued for appearing early in the spring; some of them will flower the middle of March, in mild seasons, if planted in a warm border near a wall or other shelter, and others will succeed them, so that they will keep flowering until the general feast for these flowers is come, which is towards the end of April.

It is said that the several varieties of these early-blowing tulips rife to different heights in their stems, and scarcely any two of them are equal. The Duke Van Toll, which is one of the first that appears in the spring, is generally very short-stalked, and the others, in proportion to their earliness, are shorter than those which succeed them; and the late-blowers are all considerably longer in their stems than any of the early-blowers.

The late-blowing tulips producing much finer flowers than the early ones, have engrossed almost the whole attention of the florists. It would be to little purpose to enumerate all the varieties, since there is fearlessly any end of their numbers; and what some value at a considerable rate, others reject; and as there are annually many new flowers obtained from breeders, those which are old, if they have not very good properties to recommend them, are thrown out and defiled.

It is observed further, that modern florists in Holland and Flanders, and our English florists from them, boast a prodigious variety of late-blowing tulips. And that Mr. Maddock of Walworth, in his catalogue of flowers for the year 1792, has no less than about fix hundred and fifty-five of these admired beauties, all ranged under their proper families and colours, with their names and prices: besides the early forts, double tulips, parrot-tulips, French tulips, and breeders. And moreover, that the late-blowers are distributed into five families: 1. Primo Baguet, very tall; fine cups, with white bottoms, well broken with fine brown, and all from the same breeder. 2. Baguet Rigaut; not quite so tall, but with strong stems, and very large well-formed cups with white bottoms, well broken with fine brown, and all from the same breeder. 3. Incomparable Verports, a particular kind of Byblosea; with perfect cups, very fine white bottoms, well broken with shining brown, and all from the same breeder; some of these are from two to five guineas a root. 4. Bybolea; with bottoms white, or nearly so, from different breeders, and broken with a variety of colours: those of the Verports are cherry and rose. 5. Bizarres; ground yellow, from different breeders, and broken with a variety of colours. These barbarous terms, used by the Dutch florists, are, it is said, a mixture of Dutch and French. Baguet is from the French baguette, a rod or wand, so named from its tall slender stem. Bizarre is also French, and the tulips of that family have the name from the variety and irregularity of their colours. Rigauts are probably from the name of some eminent florist, as Rigaud. The other terms are Dutch. Breeders are of one colour, and when broken produce new varieties.

It may be more particularly noticed in regard to each of the principal varieties of these tulips, that they, in every instance, comprehend a great number of intermediate ones, in so far as respects the colours and variegation, which takes place in the flower, notwithstanding each has been originally all of one and the same colour, particularly the seedling-raised bulbs, which after they have arrived to the flowering state, each separate flower is either wholly red, purple, violet, grey, brown, black, yellow, or some other indivi-

dual colour, without any fort of variegation or flripe whatever, consisting simply of one-coloured flowers, with white bottoms, with yellow bottoms; and some with blue bottoms, with purple bottoms, and with blackish bottoms; all of which, while they retain this original flamens in the colour, are, in the peculiar language of the florist, termed whole-blowers or breeders, as each flower is wholly of one and the same colour. But on the bulbs or roots being planted out for one or two years, in properly prepared soils, in order to breed, or defpefe them to gradually produce flowers, that break or run from the original single colour into variegations and flripes, in many different modes and forms, they are denominated breeders or variegated tulips, each different variegation constituting a separate and distinct variety, which molly consists of flowers with white bottoms broken, with brown flripes, with blue flripes, with violet flripes, with rofe flripes, with red flripes, and with some other kinds, separated by breaks of white, and other colours diffoped in various ways; with yellow bottoms, broken with different reds, crimsons, and golden-yellow flakes, and also a variety of other colours; and some with blackish-purple, and other bottoms broken with flripes of dark colours, yellow, and tints of red; so that, particularly in these forts of breeders or variegated tulips, which have white and yellow bottoms, there are, moreover, white and red striped flowers, white and purple striped, white and violet striped, white and rofe striped, white and brown striped, violet and white flaked, red and white flaked, red and yellow flaked; and a great number of other intermediate variegations and flripes, diffoped in an almof endless diversity of modes or manners.

The principal of these diversities or varieties are usually distinguished, in the language of the florist, by the names or titles of some great personage, eminent admirers or cultivators of flowers, places where first grown, or some other great mark of distinction; but there is such a multitude of new varieties raised annually from seed and feeding plants in different places, which are designated by new titles, without any relation to the old ones, and the name of flower so often characterised by a different name, that it would be utterly impossible to give any satisfactory list of the names of such a vast number of continually changing varieties, as has been fuggled above.

It is said that the properties of a fine variegated late tulip, according to the best modern florists, are these: 1. The stem should be strong, upright, and tall; about thirty inches high. 2. The flower should be large, composed of six petals, proceeding a little horizontally at first, and then turning upwards, so as to form an almost perfect cup, with a round bottom, rather wider at top. 3. The three outer petals should be rather larger than the three inner ones, and broader at their base: all the petals should have the edges perfectly entire; the top of each should be broad and well rounded; the ground colour at the bottom of the cup should be clear white or yellow, and the various rich flripes, which are the principal ornament of a fine flower, should be regular, bold, and distinct on the margin, and terminate in fine broken points, elegantly feathered or pencilled. 4. The centre of each petal should contain one or more bold blotches or flripes, intermixed with small portions of the original colour, abruptly broken into many irregular obtuse points. Some florists, it is said, are of opinion that the central flripes or blotches do not contribute to the beauty of the tulip, unless they are confined to a narrow flripe exactly down the centre; and that they should be perfectly free from any remains of the original colour: it is certain that such flowers appear very beautiful and delicate, especially when they have a regular narrow feathering.
feathering at the edge: but it is unanimously agreed, that the tulip should abound in rich colouring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, which should indubitably be of a clear bright white or yellow, free from flamin or tinge, in order to constitute a perfect flower.

The colours which are generally held in the greatest estimation in the variegated or striped sorts of tulips, are the blacks, the golden yellows, the purple violets, the red, and the vermilion, each of which being varied in different ways; but such as are striped with three different colours, in a distinct and unmixed manner, with strong regular breaks, with little or no tinge at all of the breeder, are supposed the most perfect. However, though it is extremely difficult to meet with such as possess all these estimable properties of good flowers of this fort, yet many are found which have sufficient perfection to become of high value as fine flowers. The double and parrot tulips are, it is said, held in no fort of esteem among florists. Among the eight sorts, however, there are many distinct varieties, in so far as regards the colouring of the flowers; as the yellow-flowered, the yellow and red-flowered, the white and red-striped, the white and blush-coloured, besides a great number of intermediate variations. And in the latter, those with long hooked petals of flowers, consisting of yellow-flowered, red-flowered, red-striped, and other kinds.

The second species has the bulb ovate, and gibbous in the shape; the stem is quite simple, nearly upright, round, smooth, leafy in the middle, and attenuated at the base, with the flower always yellow in its colour, but a little greenish on the outside.

And it is further noticed, that it has most of these characters in common with the garden species; but the circumstances that abundantly distinguish this fort are, the narrow leaves, the nodding flower, the hairiness at the base of the filaments and on the tips of the petals, and especially the simple obtuse form of the stigma, which is totally different from that of the garden tulip: the flower too is fragrant; the pollen yellow, not black; and the anthers remarkably long. But in the Flora Danica they are represented as short and round.

As this sort of tulip is of much inferior beauty to those of the other and several varieties, it is of course not nearly so much known and cultivated in flower-gardens, though it was formerly held in considerable estimation by some, before the Turkey kind became so very general; and it is still to be found in some of the older gardens of this nature, and is not undervaluing a place in those of the modern ones, among the other sorts of tulips and spring flowers, for the purpose of its early blooming and increasing the variety.

Method of Culture.—All the different sorts of tulips may be increased by offsets from the roots, and by sowing seeds to produce new varieties. The offsets should be separated from the old roots every year in June, especially for the fine sorts, on taking them up when the flowering is over, planting them in nursery-beds, in rows six inches apart, and to the depth of three, four, or five in the beginning of autumn, to remain for one or two years, until they attain the flowering state, and are proper for being set out regularly. They may also, in the old root, be planted in beds, or in the borders or other parts where they are to remain and blow, in patches of four or five, placed regularly; and to have a succession, they may be planted at different times; they are usually planted with a blunt dibble: the new roots should always be planted by themselves.

In this way the most approved sorts are propagated and continued always the same, and the flowers of any good varieties multiplied and increased as may be necessary and convenient to the growers of them.

The early and late sorts should likewise be each put in, in places by themselves; and it is advised that the roots of the early-blowing sorts should be planted the beginning of September, in a warm border, near a wall, palings, or hedge; as, when they are put into an open spot of ground, their buds are in danger of suffering by morning frosts in the spring. The soil for these should be renewed every year, where it is intended to have them fair. The best soil for this purpose is that which is taken from a light sandy pasture, with the turf cut amongst it, and to this should be added a fourth part of sea-fand. This mixture may be laid about ten inches deep, which will be sufficient for these roots, as they need not be planted more than four or five inches deep at the moat.

The offsets should not be planted amongst the blowing roots, but in a border by themselves, where they may be let pretty close together, especially when they are small; but those should be taken up when their leaves decay, in the same manner as the blowing roots, otherwise they would rot if the seafon should prove very wet, as they are not so hardy as the late blowers, nor do they increase half so fast, so that more care is requisite to preserve the offsets of them.

When these sorts come up in the spring, the earth upon the surface of the beds or borders should be gently tilled and cleared from weeds; and as the buds appear, if the seafon should prove very severe, it will be of great service to cover them with mats, for want of which many times they are blighted, and their flowers decay before they blow, which is often injurious to the roots, as it also the cropping of the flowers soon after they are blown; as their roots, which are formed new every year, are not at that time arrived to their full magnitude, and are of course deprived of proper nourishment or support.

When these flowers are blown, if the seafon should prove very warm, it will be proper to shade them with mats, &c. in the heat of the day; and when the nights are frosty, they should be covered in the same manner, by which means they may be preferred a long time in beauty: but when their flowers are decayed, and their feed-veilgs begin to filesystem, they should be broken off just at the top of the stalks, as, when they are permitted to feed, it injures the roots so greatly.

In these sorts, when the leaves are decayed, which is usually before the late-blowers are out of flower, their roots should be taken up, and spread upon mats in a shady place to dry; after which they should be cleared from fifth, and put in a dry place where vermic cannot come to them, until the sea for planting them again, being very careful to preserve every fort separate, that it may be known how to dispose of them at the time of planting.

For this purpose, it is a good method to have large flat boxes made, which are divided into several parts by small partitions, each of which is numbered the same as the divisions of the beds; so that when a catalogue of the roots is made, and the numbers fixed to each fort in the beds, nothing more is necessary in taking the roots, but to put every kind into the division marked with the same number in the bed. This saves a great deal of trouble in making fresh marks every time the roots are taken up, and effectually answers the purpose of preserving the kinds separate and distinct.

In raising these plants from seed, it is, from the time of sowing, seven or eight years before they produce flowers; and after all, they at first appear only single-coloured, often requiring two, three, or more years longer before they break.
TULIPA.

into different colours or variegations; so that the tediousness of raising seedling tulips to a flowering state often deters from the undertaking. It is, however, the method by which all the fine varieties were first obtained, and by which new varieties are still annually gained; as many persons sow some every year, in expectation that after the first fix or seven years a new flow of flowers will be produced, out of which new many varieties may annually discover themselves in each parcel. It is by this process the Dutch are so famous for furnishing such an infinity of fine varieties, supplying almost all other countries.

In effecting this business, great care should be used in the choice of the seed; the bell is that which is sowed from breeders which have all the good properties before related, for the seeds of striped flowers seldom produce anything that is valuable; and the best method to obtain it is to make choice of a parcel of such breeding tulip roots as are willed to save seeds from, and place them in a separate bed from the breeders, in a place where they may be fully exposed to the sun, planting them at least nine inches deep, as when they are planted too shallow their items are apt to decay before their seed is perfectly ripened: the flowers should be always exposed to the weather, as when they are shaded with mats, or any other covering, it prevents their perfecting the seed. About the middle of July, according to the season, the seeds will be fit to gather, as shown by the dryness of their stalks and the opening of the seed-veil, at which time they may be cut off, and the seeds be preserved in the pods till the season for sowing, being careful to put them up in a dry place, otherwise they will be subject to mould and be rendered useless. The beginning of September is the proper season for sowing the seed; for which there should be provided a parcel of hollow seed-pans, or boxes, which should have holes in their bottoms to let the moisture pass off; these should be filled with fresh sandy earth, laying the surface very even, upon which the seeds should be sown thinly as regularly as possible; some of the name light sandy earth being sifted over them, about half an inch thick. These boxes or pans should be placed where they may have the morning sun till eleven o'clock, in which situation they may remain till October, at which time they should be removed into a more open situation, where they may enjoy the benefit of the sun all the day, and be sheltered from the north winds, where they should remain during the winter seaon; but in the spring, when the plants appear with grassy leaves, they should be again removed to their first situation; and if the season be dry, they must be refreshed with water while the plants remain green; but as soon as their tops begin to decay, no more should be given. The boxes should be placed in a shady situation during the summer season, but not under the drip of trees. The weeds and mows should be kept constantly cleared off from the surface of the earth in the boxes, and a little fresh earth be sifted over them soon after their leaves decay; and at Michaelmas they should be fresh-earthed again, and as the winter comes on, be again removed into the sun as before, and treated in the same manner, until the leaves decay in the spring, when the bulbs should be carefully taken up, and planted in beds of fresh sandy earth, which should have tiles laid under them, to prevent their roots from floating downward, which they often do when there is nothing to stop them, and are destroyed. The earth of these beds may be about five inches thick upon the tiles, which will be sufficient for nourishing the roots while young. The distance of planting them need not be more than two inches, nor should they be planted above two inches deep. Toward the end of October it will be proper to cover the beds over with a little fresh earth about an inch deep, which will prevent the roots from the frost, and prevent moths or weeds from growing over them; and when the winter is very severe, it may be proper to cover the bed either with mats or peat-burn, to prevent the frost from entering the ground, as these roots are much tenderer while young, than after they have acquired strength. In the next spring the surface of the ground should be again gently tilled to make it clean, before the plants come up; and when the spring proves dry, they must be frequently refreshed with water in small portions during the time of their growth; and when the leaves are decayed, the weeds should be taken off, and the beds covered with fresh earth, as before, which should also be repeated again in the autumn. When the bulbs have been managed in this way two years, they should in the summer following, when their leaves decay, the roots being by that time considerably improved in growth, be again taken up, and planted in a fresh prepared bed, in drills three or four inches asunder, in which to remain two years longer; then, at the decay of the leaf, be again planted out into fresh beds, in rows as before, where they should be let remain to blow, being afterwards ordered as the flowering bulbs. When they are in full flower, they should be examined, in order to mark such of them as discover the best properties, that they may be separated from the others at the proper lifting season, and be replanted in beds by themselves for breeders; removing them annually at the proper season into different beds of opposite or contrary soils, as one year in poor hungry earth, the next in a much richer mould; continuing them till they break into variegations and tripes of different colours, which are the only modes by which it can be affixed. When the leaves and flower-items are decayed and withered, and the roots have ceased growing and drawing nourishment from the earth, it is the proper period for lifting or taking the old roots out of the earth, to preserve them till autumn for planting, being preferred in the manner which is directed for them above.

It may be noticed in addition, that all the sorts and varieties of tulips will grow pretty well and succeed tolerably in any soil where the earth or mould is moderately light and dry in the winter season, but that they delight most in such as are of a sandy vegetable earthy nature, and in an open sunny exposure. They are most injured by such as are of a retentive and wet damp quality, in which it is constantly necessary to have the beds in which they are put raised four or five inches above the common level of the rest of the ground. It is customary however, with florists to have the beds for this purpose composed of and prepared with different kinds of materials of the sea sand and earthy sorts, particularly for their finest kinds. But such trouble and expense are often quite unnecessary, as they succeed well enough without it; only care must always be taken not to plant them more than one or two years together, especially those fine sorts, in the same earth or bed, without changing the quality of the soil, in some measure, either altogether or in a partial manner, by some removal of the old and addition of new fresh portions of light mould, garden earth, or compost, or by a complete clearing away of the former earthy matter and the supplying of wholly new; thus rendering the blow of the tulips more strong as well as fairer. But as this is only practised for the particularly fine sorts in beds, those which are to be planted in the open border may be placed any where in the common soil, without any fear of their not flowering well.

In preparing the beds, or other parts, for the more choice sorts, the ground is to be well dug to the depth of one or two spits, and they are to be formed three or four feet in width, having alleys or intervals of one or two feet width
TULIPA.

width between them: the top or surface of each bed being raked quite even and smooth, in order for the bulbs or roots being put into it.

When they are in this state of readines for being planted, a dry day is to be selected for setting out or planting the bulbs or roots, which is to be done in rows, either in the bedding method, drilling in rows, or that of dibble-planting, a blunt-edged instrument being employed in the lathe, by way of making the holes for the bulbs as sufficiently wide below as above, and perfectly clean quite to the bottom, making out the lines lengthways of the beds at eight or nine inches distance from each other, the roots being then set in finely to the depth of three or four inches, and at the distance of six from each other in the lines. The work of planting being thus finished, the upper parts of the beds are to be raked even and smooth, which completes the whole.

The tulips intended for the open borders may either be planted in a regular line at a foot or eighteen inches distant from the edge, irregularly along it, or be disposed in separate small patches and clumps of three or four roots together in each, occupying spaces of about eight inches, some of which being placed more forwards, and others backwards, in order to afford greater diversity and variety.

When the old roots or bulbs have been thus planted out in the autumn, as they bear the winter well, nothing further is required in their culture until the vernal and summer months, when they should be preferred in quite a lean state of growth, and in some cafes the buds of the more choice sorts in the beds be sheltered and guarded from cold and severe weather in the nights, and at some other times by mats, supported archways on hoops, or other convenient means, though this is seldom absolutely necessary; or when the bedded sorts are come into flower, to preserve their beauty and duration, to shade and screen them from the excessive noon-tide sun, heavy rains, and stormy winds, by an awning of canvas or mats raised across the beds, and, in some instances, formed in a tent-like manner, in order to walk under and view the flowers at pleasure; but the flowers will blow in great perfection without these coverings and trouble, only by means of them these fine sorts will blow and continue for a longer time in full beauty than would be the case if they were openly exposed. However, as soon as ever the flowers begin to fade, all such coverings should be carefully removed, in order to permit a free circulation of air, and have the full influence of rains, dew, &c. for the nourishment and support of the root-bulbs. But when the flowering is quite past, and the flowers begin to die away, it is necessary and proper to cut off the heads or feed-velvets, especially of the fine sorts and varieties, that the roots may not be deprived of the proper quantity of nutriment for their full and perfect growth.

And in the middle of summer, when they are at rest, or have ceased growing, and the flower-velvets and other parts are quite decayed, it is time to lift or take up the old bulbs or roots, which should be done for the most part every year for the fine sorts, and every other year for the other kinds, not only for the purpose of separating the suckers or young bulbs, but also for preferring both them and the old ones without any fort of growth out of the ground until the autumn, which is the time of planting them again in fresh or newly prepared beds for the future year's bloom. At this period, therefore, when the weather is dry, the work of lifting or taking them up should be begun, which should be done with a garden-trowel, as being the best and easiest method, digging them up finely in a perfect and careful manner; and afterwards spreading them out in a shady, dry, airy place, where they may remain for a few weeks, without being acted upon by the sun or wet, and then become gradually dry and hardened; when the suckers or young bulbs, the adhering earth, and the outer decayed skins or bulks, should be taken away and removed from them, after which both the old and the young offset bulbs should be again exposed to further drying, and more effectual hardening, in the same or other more proper situation, and be ultimately put safely into some dry receptacle separately, to be kept until the proper season of planting them out again takes place. Each fort of bulbs should be planted out in a separate manner, as already noticed. See BULB and ROOT.

It may be remarked, that although the tulip may be said to be a plant of the perennial kind, yet that after the bulb of it has arrived at the flowering state or stage, the fame individual root or bulb does not always remain and continue to flower anew, but gradually wears or waifes away, as is evident by its remains at the lifting season; but previously to its dissolution it affords from its fides a new supply of suckers or young bulbs, which perpetuate the kind, one of which, being large and similar to the parent bulb, is capable of flowering equally strong for the succeeding year; so that at the end of many years, that which is often supposed to be the fame individual bulb, is in reality in very way another, or new one. In common, it is, however, termed the old bulb or root, by those who are unacquainted with the nature of such roots.

All the sorts and varieties of the tulip have flowers, which are succeeded by plenty of ripe seed in the later summer months, that is contained in the cells of an oblong capsule, the different seeds being placed on each other in double rows.

In order to fave good feed, some heads of the bell and floutell plants of each fort should be selected and left in a proper situation to blend until they become in a perfectly ripe state, which is easily known by the flets taking on a fine hard dry appearance, and the parts containing the seeds opening themselves, when they should be cut away, and the feed be taken out, and wrapt up carefully, or left to remain in them until the time of its being sown, preferring it in either way quite dry and free from any thing of a moulder nature.

In order to promote the acquisition of the vall and wonder ful diversity of colouring which often takes place in tulips, and which, in many instances, is effected in a great measure by nature only, the natural process is sometimes greatly affisted and expedited by means of proper culture and management. Thus, in the firt place, when the young feeding bulbs of the whole blowes or breeder have reached the full size, and have flowered once, by transplanting or removing them into beds of any fort of weak, poor, unfruitful earths, which, by their want of nutrient properties, may check and restrain the natural luxuriant tendency of the plants, and induce a weak enfeebled general growth, a change may be gradually produced in their general state, whereby they may break out into new variegations in the firt, second, or third years. And accordingly, as this happens, they should be planted out into beds of good earth, as has been directed above.

Another means of affisting nature in accomplishing this object is, that of making as great a change in the quality of the soil as possible, as if they were this year planted in a weak poor fort of earth, they should in the following be set out in a highly rich garden mould, and afterwards in a compost of several sorts of earth: or they may be removed and transplanted from one part of a garden to another; and
into different gardens; or in any other similar methods. All these various ways contribute in a great degree to affix in, and promote the production of, this desirable variety of colours and variegations.

The roots of all the sorts and varieties of the tulip are kept for sale in large collections by the nursery and seedmen, who have them every year in great quantities from Holland and other places, each variety of which is distinguished by some appropriate name, as has been already noticed, and arranged in regular catalogues, the prices being charged in proportion to the estimation in which they are held, which were formerly very extravagant, but are now more moderate, on account of their abundance, as from seven or twelve shillings, to as many pounds the hundred, and not unfrequently considerably more for scarce, curious, and capital sorts. The most eligible and proper season for buying or laying in a collection is in the early part of the autumn, as from August to November.

For the main collection of flowers to blow in the spring and early summer, the most proper time of planting the roots or bulbs is in the autumn, from the end of September to December; but to have a later bloom in succeffion, some may be planted out about the close of the year, and in the two beginning months of the new one. These later, however, will seldom grow so strong as those of the autumn planting.

The roots of the late sorts of tulips may be planted in any common beds, or in the borders, as they are not much liable to be injured by bad weather. But those of the finer or more valuable sorts of the early, as well as the late kinds, are in general, for the most part, disposed together, as they have been, in beds by themselves, in order to exhibit a grand blow, and be defended in the manner which has been explained.

However, some of the inferior common sorts, and even any of the capital varieties, may occasionally be distributed about the ordinary borders, in an affembly with other spring flowers of the bulbous-rooted and other kinds, in the ways which have already been directed, where they have often a fine effect when in their blowing state.

The double variety of the common tulip is very beautiful, though not held in such estimation by the florist as the common single variegated sorts, from their not pollelling that profusion of variegations in their colours, or such a regularity of stripes. They, however, exhibit an elegant ornamental appearance in their upright, tallish, firm stems, and the crowns of large double flowers at the tops, formed somewhat as in those of the double peony, but far more beautiful in their diversity of colours, variegations, and stripes of white and red, or yellow and red, &c. On these accounts they certainly deserve to be cultivated either alone in beds, at a little distance from the other sorts, for the sake of increasing the variety; or in patches about the borders, in an affembly with the common large variegated tulips, as blowing nearly about the same time in the later spring months.

The early dwarf sorts are the most proper for forcing for early blooming, and also for being placed in glasss, in rooms, &c.

These sorts are sometimes rendered more early in their blooming than would otherwise be the case, by planting the roots or bulbs in pots or boxes in the autumn or winter season, and placing them in the floor, or a hot-bed of tanner's bark, thereby bringing them into bloom in the month of January, or sooner, and continuing succeffions of them, until the natural ground blooms are ready. A quantity of bulbs is also sometimes placed upon phial-glacies containing water, a single bulb in each, during the same season, which are then put into a warm light room in the house, near the windows, or into a greenhouse or flore, in which way they often flower very agreeably in the winter and early spring, as they are well suited to such modes of cultivation.

These sorts of roots or bulbs are likewise kept by the nursery and seedmen for the purpose of sale in pretty large collections of the different kinds, under titles which are chiefly French and Dutch, as may be seen by the catalogues of these flowers which they exhibit.

Roots of these sorts may be planted out in any good, light, rich, earthy soil, where the situation is warm at the season, and in the manner stated above, in speaking of the general culture of tulips, when they will rise soon in the vernal months, and reach the blooming state about March, continuing until the late tulips come into flower. They, however, succeed best when allowed a sheltered sunny situation, as they rise and flower a few in the spring while the weather is often cold and pinching. Some of them look extremely well in the fronts of warm borders, in small patches, in affembly with alenies, ranunculums, and other similar kinds.

The second species may be managed in the same manner as those of the common sort, in so far as its culture is concerned, in much the same way, having nearly the same treatment in every respect.

They are all highly ornamental flowers, from their much varied and most beautiful colours; but those of the common garden sort, and its numberless varieties, are the most generally introduced, being admirable ornaments for beautifying the various flower borders and other parts of gardens and pleasure-grounds during some weeks in the spring and summer seasons.

TULIPIFERAR, in Botany, the Tulip-tree; see LIRIODENDRON; see also MAGNOLIA, some of whose species are called Tulip-trees.

TULIUSCHANA, in Geography, a river of Russia, which runs into the Podkamenka Tungufka, N. lat. 61° E. long. 97° 34'.

TULIKOWO, a town of the duchy of Waafow; 16 miles N.N.E. of Kalish.

TULL, Jethro, in Biography, a distinguished agriculturist, was a descendant of a respectable family in Yorkshire, educated at one of the universities, and admitted a barrister of the Temple towards the commencement of the 18th century. Returning from the tour of Europe, in which his attention was particularly directed to agricultural subjects, he married, and settled upon a paternal farm in Oxfordshire, which gave him an opportunity of prosecuting a variety of experiments in husbandry. Upon his return from France and Italy, which he was under a necessity of visiting on account of his impaired health, and with a fortune also impaired, he took a farm near Hungerford, in Berkshire, where he purposed his plans for improved cultivation. His grand principle was, that labour and arrangement would supply the place of manure and following, and raise more grain at a less expense. (See Horing, Husbandry, and Drilt-Husbandry.) Tull, in 1731, printed "A Specimen" of his system; and in 1733, "An Essay on Horf-hee Hoing Husbandry," fol. which was translated into French by Du Hamel. He purposed his system till his death, which happened in Jan. 1740.
into which the river Munry discharges itself, and which is opposite to the northern part of Achill island.

TULLAMORE, a post-town of the King’s county, Ireland, so called from the river Tullamore, which divides it into two nearly equal parts. This is a neat thriving town, owing partly to the well-directed exertions of the proprietor, lord Charleville, whose demeine extends to the suburbs, and partly to the advantage of the Grand Canal passing close to it. Here are a barrack and market-house; and, what is of still greater importance, the linen manufactory has been introduced with a prospect of success. Tullamore is 46 miles W. by S. from Dublin.

TULLE, a city of France, and capital of the department of the Corrèze; before the revolution the capital of Lower Limousin, and fee of a bishop suffragan of Bourges; 58 miles S. of Paris. N. lat. 45° 16’. E. long. 1° 51’.

TULLEN. See Toolen.

TULLINS, a town of France, in the department of the Aisne; 12 miles N.N.E. of St. Marcelin.

TULLIS CREEK, a river of Virginia, which runs into the Potomack, N. lat. 39° 33’. W. long. 78° 2’.

TULLN, a town of Austria, on a river of the same name; the fee of a bishop, suffragan of Paffau; 13 miles W.N.W. of Vienna. N. lat. 48° 18’. E. long. 16° 3’—Allo, a river of Austria, which runs into the Danube, at the town of Tulln.

TULLOARGAUM, a town of Hindoostan, in Vifa-pour. In 1779, when major-general Egerton was marching towards Poona, this town was burned by the Maharratts themselves; 12 miles N.W. of Poona.

TULLOCH-ARD, a mountain of Scotland, in the south-west part of Ross-shire. In feudal times, by burning of pitch on this mountain, all the tenants and valettis of Scarforth assembled at the castle of St. Donan in twenty-four hours.

TULLONG. See Pulo-Tullong.

TULLOON, a town of Hindoostan, in the cincr of Sirhind; 35 miles W. of Sirhind.

TULLOW, a post-town of Ireland, in the county of Carlow, pleasantly situated on the river Slaney, over which it has a bridge of six arches. The castle, which was deemed formidable, and which was reduced by Cromwell, has been converted into a barrack. Here are a neat church and a good market-house; and near the bridge the ruins of an old abbey, which, with all its possessions, was granted by queen Elizabeth to Thomas, earl of Ormond, in 1557. Tullow is 38 miles S.S.W. from Dublin.

TULLUM, Toul, in Ancient Geography, a town of Gaul.

TULLUS HOSTILIUS, in Biography, was selected king of Rome, after the death of Numa, in the year B.C. 672. He began his reign with rendering himself popular, by dividing a portion of the regal lands among those who had no such property; but deviating from the course pursued by his pacific predecessors, he contrived by a stratagem to engage the Romans in a war with the Albans. The Albans declining a combat, Tullus proposed an union between Rome and Alba, and for the accomplishment of this object, that the principal Alban families should settle at Rome. To this proposal the Albans objected, but it was agreed that the superiority of either city should be decided by a combat between three persons of each city. (See CURIAIHM and HORATIHM.) The superiority of Rome having been thus determined, Tullus proceeded to punish the Fidenates for their alleged misconduct in the Alban war; and having summoned Mettius Fufcitus, the Alban dictator, to join him with the troops of his nation, the dictator apparently complied, but in an engagement that ensued proved treacherous. The Romans, however, obtained a complete victory. Tullus and Mettius practised the same kind of ill-treatment: whilst the former courteously received the congratulations of the latter, he sent a body of troops to demolish the city of Alba in the absence of its soldiery, and at the same time ordered the Roman and Alban troops to attend him in his camp unarmed, but he privately instructed the Romans to provide themselves with swords under their garments. Charging Mettius with perfidy, he ordered him to be seized, and to be fastened between two chariots, and thus to be torn to pieces, as an emblem of his attempt to dissolve the union of the two states; the frith and laft example, says Livy, of a punishment in which little regard was paid to human laws! His accomplices were also put to the sword; the rest of the Albans were conveyed to Rome, and henceforth formed one people with the Romans. Alba, with the exception of its temples, was razed; and for the accommodation of the new inhabitants, mount Cælius was taken into the compacts of Rome.

Having subdued the Fidenates, Tullus made war against the Sabines and conquered them, and then summoned the Latin towns dependent upon Alba to acknowledge the supremacy of Rome, whose country, on their refusal, he invaded. In his old age, however, he exchanged his military prowess for the weaknefs of superstition; and terrified by prodigies and apprehended tokens of the displeasure of the gods, he had recourse to a variety of expiatory rites. The manner in which his life terminated has been differently represented. Some fay that his palace wastruck by lightning, which destroyed him and his family; whilst others have charged his murder on Ancus Martius, his successor, who is also suspected of having set fire to his palace. He died, however, after a reign of thirty-three years, during which he enlarged the size and population of Rome, with little addition to its territories. Livy. Dionys. Hal. Gen. Bog.

TULLY, in Geography, a town of Hindoostan, in the cincr of Ellichpour; 20 miles E.S.E. of Ellichpour.

TULLY, a township of New York, on the S. line of Onondaga county, 14 miles S. of Onondaga; bounded N. by Otisco, E. by Fabius, S. by Cortland county, W. by Spafford, which was erected from the W. half of Tully in 1811. It is now formed of the N.E. quarter of the military township of Tully, the S. half being Preble, in Cortland county. Its waters are small, being head-streams of Onondaga creek, and also of Thongniocoa creek, of Chenango, of the Susquehanna, &c. The whole is well watered by springs and brooks. Like Spafford, this town has ridges of hills on the E. and W. boundaries, but its valleys are extensive, rich and productive. Tully flats are much admired. The settlements commenced about 1796, and the lands are held by right of soil, principally by farmers from the eastern states. In 1810, the population was 1092, and the senatorial electors 67; but these aggregates are now diminished nearly one-half by the creation of the town of Spafford from the W. part in 1811. Tully is now about five miles square.

TULLYCLEA, a small river of Ireland, rising in the southern part of the county of Tyrone, and discharging itself into lough Erne, a little to the north of Devenish island.

TULMERO, a town of South America, in the province of Venezuela, situated in the vale of Aragua, two leagues from Maracay. This town is modern, well built, and the residence of a number of planters; but it is peculiarly the abode of all the officers, factors, and persons employed in the administration of the tobacco cultivated in its vicinity,
vicinity, on account of the king. Here are a landfome church, a vicar for the religious department, and a lieutenant of justice for the civil. Its population consists of 3000 persons.

TULOMA, a river of Ruffia, which runs into the La-
doga lake, 32 miles N.W. of Onelnet.

TULON, a town of Thibet; 45 miles E. of Tankia.

TULONIUM, in Ancient Geography, a town of the in-
terior of Spain, belonging to the Varduli, according to Ptolemy. In the Itinerary of Antonine, this place is on the route from Alturca to Burdigala, between Sulflatum and Alba.

TULOS, a word used by some medical writers to ex-
cuss a callus.

TULOSTOMA, in Botany, so named by Peron, from tuba, a sward, or other protuberance from the skin, or filfus, and squam, the mouth; which is exactly descriptive of the little orifice, by which the powdery feeds of this fungus are dis-

Eff. Ch. Receptacle conciitous, globular, falked, dis-
fching the powdery feeds, intermixed with hairs, by a cyndrical cartilaginous mouth.

colour, fixed by fibrous annual roots. Head globofhe, smooth, half an inch or more in diameter, with a small, regular, orbicular orifice at the top, whose edges are flat and cartilaginous.

2. T. squamosum. Scaly Stalked-Puff-ball. Perf. n. 2. (T. brumale 2; ibid. Lycoperdon pedunculatum; Sowerb. Fung. t. 206, the difected figure, and fome near it. L. pedunculatum axifereum; Buillard Fung. v. 1. 161. t. 471. f. 2. L. album mammofeo, pediculo longo et veluti squa-
mofo, ac futilolo, donatum; Mich. Gen. 218. (p. 97. f. 7.)—Stalk fally, bollow, with a central thread. Orifice pro-
minent, tubular.—Found by Micheli, on banks near Flo-
rence. Mr. Sowerby received his specimens from Norfolk, by favour of the Rev. Dr. Sutton. Buillard seems to have gathered his in France. We preume this must be a diftinct species, well marked by the above characters.

3. T. giganteum. Great Stalked-Puff-ball.—Stalk woody, clothed with upright facles.—Gathered at Owlyheke, by Mr. Archibald Menzies. Mr. Sowerby fays this is "a gigantic representation, as it were," of the common kind, the flalk being twice as long, and four times as thick, more woody, and fometimes truly quafmofo, the fquame pointing upwards. The fize of the head is in proportion. We know this fungus only from Mr. Sowerby's incidental account, but have no doubt of its being a diftinct species, in which more particular investigation might discover more defcrive characters; and on this account we record it here.

TULOUR, or Tanna Labe, in Geography, an island in the East Indian sea, about 90 miles in circumference. N. lat. 4° 45'. E. long. 124°.

TULP, Nicholas, in Biography, an eminent physician,
was the fon of an opulent merchant, and born at Amfterdam, in 1593. Having studid and graduated at Leyden, he settled in his native city, and rose to a high
rank, not only in his profeflion, but as a citizen. Under
the latter denomination he was distinguished by the high
posts which he occupied, and by the favours which he ren-
dered to his country. As burgomaster, to which station he
was advanced in 1652, he refited the invasion of Holland
by Lewis XIV. in 1672, and thus saved his country; on
which occafion a medal was struck to his honour with this
motto, from the Axeide, "Vires uter forte quem feneet." Having completed his 80th year, he died in 1674. Tulp's
"Observationum Medicarum Libri tres," 1642, 12mo. have been feveral times reprinted, and contain many valuable
physiological remarks. He is faid to have been among
the first who oberved the lactic acid. Haller. Eloy.

TULPEHOCKON, in Geography, a township of Penn-
sylvania, in the county of Berks, which, together with
Bern and Bethel, contains 5800 inhabitants.

TULPEHOCKON Creek, a river of Pennsylvania, which runs into the Alleghany, N. lat. 45° 22'. E. long. 76° 58'.

TULSK, a poit-town of Ireland, in the county of Ros-
common. The magnificent and indiferminate ruins of cables and churches, bear ample testimony to its former
importance, but it is now a wretched village. Tulsk was
repreented in the Irish parliament, but loll its privilege at
the Union. It is 754 miles W.N.W. from Dublin.

TULSKOE, a government of Ruffia, bounded on the north by Moskvokata, on the eafh by Riazankof and Tam-
bovskoe, on the south by Orlovkoe, and on the west by
Kuluzko; 120 miles long, and from 40 to 100 broad.
Tula is the capital. N. lat. 53° to 55°. E. long. 36° to 38°.

TULUM, a town of Peru, in the province of Ghilan; 10 miles S. of Refhid.

TULUN, a town of Ruffia, in the government of Ir-
kutk, on the Ija; 44 miles E. of Niznei Dufnik.

TUMAGURRA, a town of Bengal; 18 miles N. of
Toree.

TUMANSKOI, an island of Ruffia, in the Frozen
ocean, of a triangular form, lying north of the ifle of Kirlah, from which it is divided by a narrow channel; about 350
miles in circumference. N. lat. 71° 50' to 73° 15'. E.
long. 116° to 126°.

TUMANUNA, in Ancient Geography, a municipal town
of Africa, in Mauritania Caefariensia, according to the Table of Ptolemy.

TUMARRA, a town of Africa, in Mauritania Caefariensia,
Ptolemy.

TUMB, or Tombo, or Potombo, or Cataseto, or Slangen,
or Great Tumb, in Geography, an island in the Perifian gulf, about three miles in length from eaf to weft, and much
frequently by trankeyes from the Arabian shore, which refide here a week or ten days for the benefit of fishing. A fandy
bay on the eafit fide fens a good landing-place. N. lat.
26° 24'. E. long. 55° 38'.

TUMB Namiu, or Little Tumb, a small island in the Perifian gulf; 10 miles S.W. of Tumb.

TUMBABA, a word used by chemifls to exprefs ful-
phur vivum, or crude sulphur.

TUMBACH, in Geography, a town of Bavaria; 17
miles N.N.W. of Amberg.

TUMBADO, a small island among the Bahamas. N.
lat. 26° 24'. W. long. 79° 30'.

TUMBALA, a word used by some authors, to exprefs
the fquame, or fcales, of any metal.

TUMBALLA, in Geography, a town of Hindooftan, on
the coaft of Malabar; 25 miles S. of Cochin.

TUMELEN ISLANDS, a cluster of small islands in the
East Indian fea. N. lat. 1°. E. long. 107° 58'.

TUMBERIDIPAL, a town of Hindooftan, in Mysore; 22 miles N. of Daraporum.

TUMBEZ,
TUMBEZ. a town of Peru, in the jurisdiction of Piazza, near a river of the same name, which discharges itself into the bay of Guayaquil, almost opposite to the island of St. Clare. Barks, boats, balzas, and canoes, may go up and down this river, being three fathoms deep, and twenty-five fathoms broad; but it is dangerous going up it in the winter season, the impetuosity of its current then increasing by torrent from the mountains. At a little distance from the Cordillera, on one side of the banks of the river, stands the town of Tumbez, in a very sandy plain, interspersed with some small eminences. The town consists only of seventy houses, built of cane and thatched, scattered up and down, without any order or symmetry. In these houses are about 150 families of Meficos, Indians, Mulattoes, and a few Spaniards. There are, besides these, other families living along the banks of the river, who having the convenience of watering their grounds, continually employ themselves in rural occupations. The heat is excessive; nor have they here any rain, for several years successively: but when it begins to fall, it continues during the winter. The whole country, from the town of Tumbez to Lima, contained between the foot of the Cordillera and the sea, is known by the name of Valles. Tumbez was the place where, in 1526, the Spaniards first landed in these parts of South America, under the command of Don Francisco Pizarro, and where he entered into several friendly conferences with the princes of the country, but vainly to the Incas. If the Indians were surprised at the sight of the Spaniards, the latter were equally so at the prodigious riches which they every where saw, and the largeness of the palaces, cathedrals, and temples, of all which, though built of stone, no vestiges are now remaining; 280 miles N. of Truxillo. S. lat. 3° 14′; W. long. 89° 47′.

TUMBLER, a name given to a particular species of pigeon, called by Moore the columba revolvent. See Pigeon.

It has its name from its peculiar property of tumbling when it is in the air, which they are very fond of doing; and effect exactly in the same manner as our posture-masters do it; by throwing themselves over backward. It is a very small pigeon, and is always short-bodied, full-breasted, thin-necked, narrow-beaked, and has a small short head; the iris of the eye in this species is usually of a bright pearl-colour.

The English tumbler is usually of one plain colour; black, blue, or white; the Dutch is much of the same make, but has different colours, and is sometimes feathered on the legs; it has also a larger head, and thin skin round the eye. Some of the small pigeons of this sort are bred from a mixture of the Dutch and English kinds. These pigeons are remarkable for the height to which they fly; they never ramble far from home, but will rise almost perpendicularly, till they appear no larger than a sparrow, or become quite out of sight; they will often keep at this height five or six hours, and then come gradually down again: they never tumble when they are at any great height, but only as they ascend or come down again. There are particular times also, at which these birds will take much higher flights than at others; but they ought to be kept by themselves, and practised to it by the company of one of their own species; for if they mix while young with other pigeons, they will learn to fly as they do; a flight of a dozen of these birds sent out together, will keep so close, as to be all in a compass that might be covered with a handkerchief; but they should never be turned out in foggy weather, or in high winds; in the full cafe, they lose sight of their home, and perhaps never find it again; and in the other, they are blown away; and if they return, it is not till another day; in the mean time lying out, they are in danger of cats, and other accidents.

Lastly, the hen should never be turned out with egg, for she is then sick, and not fit for flying; and beside often drops her eggs, and the breed is lost by it. Moore's Columbarium, p. 39.

TUMBLER is also a fort of dog, called in Latin vertagus, from his quality of tumbling and winding his body about, before he attacks and fallens on the prey. See Dog.

This species took its prey by mere subtlety, depending neither on the sagacity of its nose, nor its swiftness; if it came into a warren, it neither backed nor ran on the rabbits; but by a seeming neglect of them, or attention to something else, deceived the object till it got within reach, so as to take it by a sudden spring.

These dogs are often less than hounds; being lanker, leaner, and somewhat prick-eared; and by the form of their bodies, they might be called mungrel greyhounds, if they were a little bigger. They seem to answer to our modern lurchers.

TUMBLING-BAY, in a Canal, is the name with overfall or weir; which fee.

TUMBLING Dam, in Geography, a place on the river Delaware; 20 miles above Trenton.

TUMBLING-Home, the inclination of the top-sides of ships from a perpendicular towards the centre or middle line of the ship. The top-sides of three-decked ships have the greatest tumbling-home, not only from their being lofier, but for the purpose of clearing the upper works from the smoke and fire of the lower guns. The advantages and disadvantages of tumbling-home sides will be found discussed in Ship-building; which fee.

TUMBREL, TUMBLERUM, a ducking or cucking flool, an engine of punishment, which ought to be in every liberty, that has a view of frank-pledge, for the correction and cooling of scolds, and unquiet women.

TUMBREL, in Artillery, is a kind of carriage with two wheels, used to carry the tools of the pioneers and miners, and sometimes likewise the money of the army.

TUMBREL is also a common name for a dung-cart.

TUMBRIL, SHEEP, a contrivance of the balest kind for the purpose of keeping different farts of food for the use of them. It consists of a fort of circular cage or basket made of oyers, willows, or any other plants of the bruishwood kind. It is about ten feet in circumference in the whole, and closely wattled to the height of about one foot, above which it is left open for the space of eighteen inches; it is then wattled again to the height of eight or ten inches more, and an opening, about eighteen inches in breadth, is left at the top, for putting in the hay, roots, or other lasts of food, whether green or dry. The flaves which form the skeleton of it are put in inches amber, so that twelve sheep may feed at it at the same time.

Considerable advantage may be derived from this simple contrivance in the feeding of these animals, as it not only effects a material reduction in the consumption and expense of the provender, which is by this means prevented from being trodden under foot, or failed by the dung; but in this state of separation the stronger sheep cannot drive away the weaker, as each is secured by the head. And as the construction of such tumbrils is attended with no difficulty, they may be easily provided and conveyed to any part of a farm, and with due care be kept in constant use for eight or ten years, or even much longer.

TUMBUK, in Geography, a town of Africa, in Kordofan; 180 miles S.W. of Scourar.
TUMEFACTI ON, the act of swelling, or rising into a tumour.

Inflammations and tumefactions of the teats frequently happen in the gonorrhoea; either from the weaknesses of the vesicles, violent motion, unfeorable use of alliments, a neglect of norrying, or the like.

TUMEN, in Geography, a town of Persia, in the province of Ghilans; 18 miles W. of Rehad.

TUMERIZ, a town of Moravia, in the circle of Brunn; 6 miles W. of Nicolibus.

TUMEX, in the Materia Medica of the Ancients, a name given by authors to a sort of tumty, the fame with the curdul placitis of Dioscorides and the Greeks. This was a worse kind than the botryitis. See TSPANI.

TUMMARRAH, in Geography, a town of Africa, in Sabara.

TUMMEL, a large river in Perthshire, Scotland, rises on the confines of Argyelshire. Near its source it forms a broad lake, called Loch Rannock, at the termination of which the river assumes the name of the Tummel. In its progress it forms another lake, called Loch Tummel, in which is a small island, with an old fortress or castle, formerly the residence of the chief of the clan of the Robertsons. The whole course of the Tummel is rapid and furious, and in several places forms very romantic and picturesque cascades. One of its falls, near its junction with the Garry, is particularly grand, as its whole water is precipitating over the broken rocks with afflicting violence. After its union with the Garry, the character of the Tummel seems entirely changed: before, it was an impetuous torrent; it now becomes a quiet and placid stream. The banks below the junction are extremely rich, and the river meanders through a fine valley; now dividing its stream, and forming small islands, now running in a broad sheet. Though the Tummel is smaller than the Garry, it gives the name to the river formed by their union, because it can trace its origin farther back than the Garry, which is composed of the waters of the neighbouring hills, while the source of the Tummel is a considerable lake, in its course from which several distant streams contribute to its importance. The Tummel pours its waters into the river Tay at Logierat.—Garnet's Tour through the Highlands, 4to. 1806. Beauties of Scotland, vol. iv. Perthshire, 1806.

TUMMEROO, a town of Meckley; 25 miles S.E. of Munypour.

TUMMOO, a town of Meckley; 45 miles S. of Munypour.

TUMOURS. The meaning of the word tumour, in Surgery, is exceedingly comprehensive; for it applies generally to the growth of all diininct superfluous parts, or subflances, which did not make any portion of the original structure of the body, as well as to every morbid increase in the bulk of other parts, which naturally and always existed in the human frame. Within this definition will come the greater number of diseases; as cysts or droops, bronchocles, adena, fungus hematoles, hydrocele, ganglions, inflammations of various organs, white swellings, aneurisms, ulcers, haemorrhods or piles, exabiolism, excrescences, polypi, hernia or ruptures, scirbus, worss, &c. &c. (See these words.) Had it, therefore, entered into our arrangement to confider, in the present article, all the diseases which may be classed as tumours, we should have had a very tedious and laborious task indeed, namely, that of writing out and prefiguring to the reader, in this part of the Cyclopaedia, a description of the nature and treatment of at least two-thirds of all the diseases usually considered as surgical. Our plan, however, has been different; and for the sake of avoiding all occasion

for so long a production, we have treated of numerous kinds of tumours in separate articles, which are alphabetically distributed in this Dictionary.

In the present article, we propose to offer a few general remarks on the formation of tumours; to describe particularly those of the encysted and fcaromalous kinds; and to give some account of the manner of removing tumours in general.

It is difficult to give altogether an unobjectionable account of the formation of tumours, the secrets of which processes will perhaps never be disclosed. We know that parts become thickened and enlarged by inflammation; but the causes of the origin and growth of all such swellings as are conflit of some new production, which made no part of the original composition of the body, may be said to be totally unknown. In Mr. Abernethy's surgical works will be found some remarks upon this subject, which are far more rational and interesting than those generally advanced.

"The incipient flate of tumours," he observes, "will naturally first engage our attention; and those which perhaps form the belt example and illustration of the subject, are such as hang into cavities from the membranous surfaces, which form their boundaries. The cause of tumours having a pendulous attachment attracted the attention of Mr. Hunter, who made the following remarks on the formation of one on the inner surface of the peritoneum, as is related by Sir E. Home, in the Transacti ons of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. i. p. 231. "The cavity of the abdomen being opened, there appeared lying upon the peritoneum a small portion of red blood recently coagulated: this, upon examination, was found connected to the surface, upon which it had been deposited, by an attachment half an inch long; and this neck had been formed before the coagulum had lost its red colour.' Now had vessels shot this flender neck, and organized the clot of blood, as this would then have become a living part, it might have grown to an indefinite magnitude, and its nature and progress would probably have depended on the organization which it had assumed. I have," says Mr. Abernethy, "in my posefion a tumour, doublets formed in the manner Mr. Hunter has described, which hang pendulous from the front of the peritoneum, and in which the organization and congequent actions have been so far completed, that the body of the tumour has become a lump of fat, whilst the neck is merely of a fibrous and vascular texture. There can be little doubt, but that tumours form every where in the same manner. The coagulable part of the blood, being either accidentally effused, or deposited in congequence of dilatae, becomes afterwards an organized and living part, by the growth of the adjacent vessels and nerves into it. When the deposited subflance has its attachament by a single thread, all its vasculaf supply must proceed through that part; but, in other cases, the vessels shoot into it irregalarly at various parts of its surface. Thus, an unorganized concrete becomes a living tumour, which has at first no perceptible peculiarity as to its nature; though it derives a supply of nourishment from the surrounding parts, it seems to live and grow by its own independent powers; and the future structure, which it may acquire, seems to depend on the operation of its own vessels. When the organization of a gland becomes changed into that unnatural structure, which is observable in tumours, it may be thought in some degree to contradi thes observations; but, in this case, the subflance of the gland is the matrix, in which the tumour is formed.

"The structure of a tumour is sometimes like that of the parts near which it grows. These which are pendulous into joints
TUMOURS.

joints are of a cartilaginous or osseous fabric; fatty tumours
frequently form in the midst of adipose substance; and I
have seen from tumours growing from the palate, and hav-3
ing a slender attachment, which in structure resembled the
palate. Sometimes, however, they do not resemble in struc-
ture the parts from which they grow. The infance, just
mentioned, of the pendulous portion of fat growing from
the peritoneum, will serve as a proof: the vessels, which
had shot into it, made the tumour into fat, whisth the neck
was a fibrous and vascular structure. I have seen these
6 tumours unconnected with bone, or periosteum; and, in-
deed, in general, the structure of a tumour is unlike that of
the part in which it is produced. Therefore, we seem
warned in concluding, that, in many cases, the nature of the
tumour depends on its own actions and organization; and
that, like the embryo, it merely receives nourishment from
the surrounding parts.

"If, then, the coagulable part of the blood be from any
cause effused, if the adjacent absorbents do not remove it,
and the surrounding vessels grow into it, the origin of a
tumour may be thus formed. It may be right," says Mr.
Abernethy, "to reflect a little on the caules which may
occasion a deposition and consequent organization of the
cogaulable part of the blood; as such reflexions throw
light on the nature and growth of tumours, and lead to the
establishment of principles, which are applicable to tumours
in general. The deposition of the coagulable part of the
blood may be the effect of accident, or of a common in-
flammatory process; or it may be the conquence of some
diseased action of the surrounding vessels, which may in-
fuence the organization and growth of the tumours.

"In the former cases, the parts surrounding the tumour
may be considered simply as the sources from which it de-
vires its nutriment, whilst it grows apparently by its own
inherent powers, and its organization depends upon actions
began and existing in itself. If such a tumour be removed,
the surrounding parts, being found, soon heal, and a com-
plete cure ensues. But if a tumour be removed, whose ex-
sistence depended on the diseafe of the surrounding parts,
which are still left, and this diseafe be not altered by the
fpuilus of the operation, no benefit is obtained: these
parts again produce a diseased substance, which has gen-
early the appearance of fungus; and, in conquence of being
irritated by the injury of the operation, the diseafe is in
general increased by the means which were designed for
its cure. It appears, therefore, that, in some cases of tu-
mours, the newly formed part alone requires removal;
whilst, in others, the surrounding substance must be taken
away, or a radical cure cannot be effected.

"There is yet another circumstance deserving attention,"
says Mr. Abernethy, "before I proceed to the particular
consideration of the subject; which is, that a tumour, once
formed, seems to be a sufficient cause of its own continuance
and increase. The irritation which it caues in the contiguous
parts, is likely to keep up that increased action of the vessels,
which is necessary to its supply; and the larger it becomes,
the more does it stimulate, and of course contribute to its
own increase.

"Suppose then a tumour to have formed and increased;
it will continue to grow, and to condense the surrounding
cellular substance, and thus acquire for itself a kind of cap-
fule. Tumours are more closely or loosely connected to
the surrounding parts; which circumstance seems to depend
upon the degree of fullness which they occasion, and the
inflammation which they thus excite. This irritation per-
haps may be the cause why some tumours, which are flow
in their first increas, grow rapidly after they have acquired a
Vol. XXXVI.

We regard the preceding account of the formation of tumours as the most rational and probable which has hitherto
been offered.

All tumours, which are such as may be termed new-
formed parts, and did not enter into the original structure
of the body, appear to be ended with inferior powers of
life, and are much sooner destroyed by inflammation than
other parts, which always naturally exist in the animal
frame. The knowledge of this fact has led to the method
of curing several kinds of tumours, by the application of
simulating substances to them; but it is not a plan of treat-
ment which will invariably answer. Some tumours are so
large, that the constitutional illnefs, which would arise from
the inflammation and sloughing of the whole of their mass,
would in all probability be fatal. Some swellings are of a
malignant, irritable character, fo that applying stimulants
to them is more likely to exasperate than cure the diseafe.
Hence, it is generally deemed imprudent to apply caufes
to cancerous affections; because unless every particle of
such diseases, and a good deal of the surrounding substance,
be destroyed by the action of these violent remedies, the
cafe will not be benefited, but rendered ten times worse.
Indeed, we may lay it down as a general maxim, that the
plan of attacking tumours with stimulants and caufes is a
bad one, unless it be certain that every particle of the difeafe
may be in this manner easily and quickly destroyed, without
too much local and constitutional irritation being pro-
duced.

Encysted Tumours.—In the midst of the subcutaneous cel-

eral substance, of that which separates the muscles, or even
of that which enters into the texture of different organs.
Tumours are observed to form, whose circumference pren,
its a particular structure, and whose cavity is filled with un-n
usul kinds of matter. The parietes of these tumours are
composed of a fort of membrane, named a cyst, and are con-
ected with the surrounding parts by means of the neigh-
bousing cellular substance. This latter circumstance appears
have attracted the attention of a great many writers, who
have conceived the formation of cysts, by supposing that
a cavity of the cellular membrane, in conquence of diseafe,
may have all its communications with the other cavities of
the cellular membrane destroyed; that it may acquire the
property of secreting matter entirely different from that
which it secretes in the natural order of things; and that
the accumulation of the deposited substance may produce a
progressive dilatation of the small cavity. The layers of
the cellular substance, in which the tumour develops itsel,f,
are afterwards supposed to undergo a kind of condensation;
and by this theory, it is attempted to explain the consi-
derable thicknefs of some cysts, the extraordinary appear-
ces of their organization, and the possibility of reduc-
ing them into cellular substance by maceration, inflammation,
f uppuration, &c. It is difficult, observes M. Delpech, to
adopt this opinion, and reconcile it to the following ob-
ervations.

1. There are some thin transparent cysts, which have
been termed frous, whose inner surface is villous, and whose
cavity is filled with a fero-mucous secretion, resembling
fynovia. In the same cavity, hairs are frequently observed,
which are of different lengths, and always curled; the roots
being implanted into the sides of the cyst.

2. There are other cysts, which are generally of a thin,
but much more compact, texture than cellular membrane;
being, as it were, almost horny and half opaque. Their
inner surface is pulpy, and sometimes irregular. Their

3D cavity
TUMOURS.

cavity is filled with a fluid, that has more or less confluence, is pultaceous, and of a white or yellowish colour, being compared sometimes to pop, sometimes to liquid honey, and in other instances to sue imperfectly melted. Hence, the names of atheroma, meiricis, and flectoma, by which they are commonly distinguished. The contents of these encysted

3. We observe some cysts formed of albumen converted into a fibrous texture, and whose organization is more or less imperfect. Particular cysts of this latter kind are composed of several concentric layers, which are only slightly adherent together, and the organization of which is unequally advanced. In such a case, M. Delpech has found the external layers made up of a perfectly fibrous texture; while the vestiges of an organized structure were much less evident in the subjacent layers, and altogether wanting in those most deeply situated, which were purely albuminous. The contained matter is of an albuminous or gelatinous quality.

4. Other cysts are what Delpech calls fibro-cellular; their sides are very thick, extremely compact, and sometimes even offished in certain parts. The contents are almost like scum, occasionally tinged with blood.

5. Exceeding this last sort of cyst, which is closely connected with the surrounding cellular membrane, and almost identical with it, there is, of every kind of cyst, a portion of the surface which fearfully has any adhesion to the circumjacent parts. In extirpating such tumours, if the surgeon makes a perpendicular cut through the parts, covering their external surface, he can afterwards completely detach them with the utmost facility. In short, they can be separated with a spatula, or any other blunt instrument, without any difficulty.

6. Sometimes inflammation attacks the cellular membrane around the cyst, and terminates in suppuration. One or more spontaneous openings serve at first for the discharge of the abscess; but these are at length joined together by the effect of ulceration, and the whole mortified cyst sloughs away. The same thing is occasionally seen, when caustic has been applied to the skin covering the most prominent part of the swelling. The application not only produces an effusion of the integuments, it causes also an acute inflammation of all the cellular substance around the tumour, and mortification of the whole cyst, which comes away in a mafs. Likewise, when the surgeon has been fearful of cutting out every portion of a cyst, and only opened it, or removed a part of it, with the design of completing the destruction of the rest by local applications, it has often happened that the remainder of the cyst has spontaneously sloughed away, while the surrounding cellular membrane was in a state of acute inflammation.

7. Lastly, an encysted tumour, treated in the preceding manner, has often presented phenomena resembling those of cellular substanee, and admitted of being cured in the way which was desired. Healthy suppuration has been established; granulations have arisen; the cavity has been gradually lefzened; and a solid cicatrix has at length been formed. But it has much more frequently happened, that the cavity has not been obliterated; but become filled with painful, bleeding, fungous excrements, which have caused an apprehension of cancer, and a necessity for no longer deferring the extirpation of the diseaee.

These reflections appear to M. Delpech to justify the conclusion, that encysted tumours do not proceed from an accidental or mechanical modification of the cellular membrane; but that they are so many new-formed organs, which are not endowed either with the same degree or the same mode of vitality as the surrounding parts.

The causes of the formation of encysted tumours are entirely unknown: it is observed, however, that a strongly marked propensity to be afflicted with many such swellings exists in particular individuals, which is a fact that would lead one to suspect the operation of constitutional causes.

For infall, it is common for those firm cysts, which contain a papery matter, and which have received the appellations of atheroma, meiricis, and flectoma, to be very numerous in the scalp, or other particular situations. It is well known also that the fibro-cellular cysts, usually named dropsy of the ovary, are sometimes prodigiously numerous, either in one or both of these organs together. It is superfluous to remark, that external violence, to which encysted tumours have been often ascribed, has in reality no concern with the disease. Besides the evident disproportion between this species of cause and so great an organic change, it may be observed, that if a blow can sometimes be cited, as having preceded the formation of an encysted tumour, the same cause cannot be specified in other cases, where twenty or more of these swellings originate in suception.

An encysted tumour, at its commencement, is always exceedingly small, and of a perfectly indolent nature. It is not known whether, in this early state, the cavity of the cyst already exists. The swelling usually grows with remarkable swifness; indeed, it is often many years before it attains a considerable size. It even frequently happens, that after the tumour has become large enough to be manifold, the cyst remains stationary for years, until some irritation occurs, which renders the diseaee painful, and accelerates its progress. It appears that, in these circumstances, the latter enlargement of the tumour does not depend upon a bricker secretion of the kind of matter originally contained in it, but rather upon suppuration of the cyst. In fact, the indige of the fac is then found to be inflamed or ulcerated, and a certain quantity of pus blended with the papery matter, with which the swelling had no doubt been previously filled. This change, however, seldom happens, unless the tumour be, by its situation, exposed to repeated external violence.

An encysted swelling is ordinarily of a spherical shape, except when this form is altered by the disposition of the surrounding parts. The tumour is moveable in a degree proportioned to the mass of cellular substance around it; and its surface is in general smooth and regular. Sometimes, however, bands of aponeurotic fibres pres upon certain portions of it, as it enlarges; and thus it is rendered irregular. The same alteration may be produced by great inequality in the thickness and confluence of the sides of the cyst, or by their being weakened by internal ulceration. It is not uncommon in the beginning, and even sometimes in an advanced stage, for the swelling to have a very firm feel, either because the cyst is still of considerable thickness, and the contained matter not copious; or else because the cyst is exceedingly tenue, not having yielded to the dilution of the matter within it. In this circumstance, the swelling is not compreptible; and if, at the same time, its surface should chance to be irregular and tuberculated, and epecially if the diseaee should also be painful, the surgeon may easily make a mistake, and imagine the case to be cancer. The resemblance, indeed, is very great; and M. Delpech assures us, that he has seen practitioners of the highest merit deceived by it. But it more usually happens, that an encysted tumour presents, from the first, a soft, fluctuating,
TUMOURS.

fluctuating, doughy feel. The fluctuation is obvious enough, when the cyst is thin, and the contained matter almost all liquid. This symptom, however, is absent when the sides of the swelling are very thick and firm, and its cavity is occupied by a pappy fort of matter; but, in this last kind of case, the shape of the mass may be altered by compression, and the tumour will retain every impression made in it. If to these circumstances we add, that the tumour is every where soft and compressible, we have all the proper symptoms of this class of swellings; symptoms by which they may be most frequently distinguished from every other disease that has any resemblance to them.

The stationary condition of an encysted tumour may last during life, if the disease be not exposed to external violence, and it be free from every complication. But, as we have already explained, an accidental irritation may cause an inflammation, and suppuration, and ulceration, of the cyst. The convenience may also be inflammation and ulceration of the integuments. In both cases, the cyst may spontaneously burst, the contents escape, the cyst slough away, and the ulcer heal; or else soft, painful, fungous granulations may shoot from the inner surface of the cyst, and render cicatrization impracticable. With regard to complications, a cancerous affection, which is sometimes joined with the organization of an encysted swelling, is the most afflicting: in this case, when ulceration occurs, the carcinomatous symptoms immediately make rapid and dangerous progress.

Encysted tumours, like aneurisms, may destroy the parts of bones, upon which they make considerable pressure. Delpech, Précis Elémentaire des Maladies Chirurgicales, tom. iii. feet. 8.

A curious appearance is sometimes the consequence of an encysted tumour being filled with a substance resembling horn in consistence; for, when the cyst burst, the indurated contents gradually protrude, and sometimes form an appendage very much like horn. Some years ago, we saw a complete horn removed from the ferotum, by Sir J. Earle, in St. Bartholomew's hospital. It had begun as a tumour, which, after bursting, emitted from its inside the horny excrecence. The preparation is now in Mr. Abernethy's museum.

In the British Museum is preserved a curious specimen of a horn, which grew from a woman's head, and, in all probability, was formed by a process similar to that which we have mentioned. In Mr. A. Cooper's posseffion is a still more remarkable specimen, which was given to him by Dr. Roots of Kingston, and which in shape and size bears a close resemblance to a ram's horn! It also grew from the head, and had been preceded by another horn-like excrecence, similarly situated and shaped, which had likewise been removed. We have subsequently been informed, that the patient, who was a gardener, had afterwards a third horn, which grew in the same identical place. In this case, we must suppose that a portion of the cyst had not been exiripated in the previous operations, and that it retained the power of secreting the horn-like matter. First Lines of Surgery, p. 142. edit. 3. See also Horny Excreceries, in this Cyclopaedia; and Sir E. Home on the same subject, in the Philosophical Transactions.

We have already noticed the curious fact of many cysts containing hairs: we have now to mention the more surprising circumstance of teeth having been sometimes found in the cavities of encysted tumours. A remarkable example was lately published by Mr. S. Barnes, surgeon at Exeter. The cyst was a double encysted swelling in the orbit; in the extirpation of which disease, a sharp bony process was discovered, and removed, together with the remains of the fac which adhered to it.

On examination, it was found to stand like a tooth, and much resembling in form and size the supernumerary teeth sometimes found in the palate. The part which projected into the fac was conical, and covered, by a smooth shining, white enamel; the fac firmly adherent round a contracted portion at the base of the cone, resembling the neck of a tooth; and on the outside of the fac, the appearance of a root, truncated obliquely, with a passage in the centre, evidently containing blood-vessels. It was by this part that it was connected with the floor of the orbit. See Medical-Chirurgical Transactions, vol. iv. p. 316, et seq.

Practitioners are not acquainted with any effectual means of stopping the growth of encysted tumours; nor are the endeavour to promote the disferion of the cyst and its contents by general or topical treatment, attended with any success. It has been alleged, that, in cases of what have been called Leo-mucoi cysts, the removal of these cysts and their contents might be brought about, by exciting the action of the absorbents with strong difcuent topical applications; and instances of this mode of cure have been cited in relation to such swellings formed upon the patella, or at the extremity of the olecranon. But Delpech remarks, that, in these cases, the nature of the disease is mistaken, because, in the situations specified, there constantly exists a fynovial membrane, a bursa mucos, forming a kind of joint betwixt the bony prominence and the integuments. The fynovia may accumulate and lodge in the cavity of the mem- branous sac; and if the membrane be not thoroughly diseased, as to render the absorption of the fynovial fluid impossi- ble, the natural functions of the part may be re-estab- lished, and the swelling admit of being slowly disserened. This is what is sometimes accomplished by different local remedies, particularly those of the difcuent class. But if the fynovial membrane is more completely diseased, its properties may be so altered, that the secretion from it is altogether of a different nature, and absorption is totally obstructed. This is what sometimes occurs in persons who are in the habit of kneeling a great deal; in them the fynovial membrane is often considerably thickened; sometimes it is partly ossified; and Delpech mentions, that he has even found loose substances in its cavity. Here we see, that in the fift instance, an immediate cure is possible, since the disease is not an organic alteration. But in the second example, which more resembles the state of encysted tumours, although it be only the change of a pre-existing organ, the affection cannot be cured without destroying the dis- tempered part. Delpech, with a view of opposing evident facts to such as are wrongly interpreted, or doubtful, ad- verts particularly to those leo-mucous cysts which so often form in the substance of the eye-lids. The apprehension of a fear upon the face, says he, confantly leads to a trial of topical refolvents, before extirpation is attempted. Surgeons know, however, that the tumours are not removed by absorption; and that, if the local applications sometimes accomplish the cure of the disease, it is by producing an irritation of the skin, which irritation extends itself to the cyst, where inflammation, suppuration, ulceration, and floughing, are the consequences. But, generally speaking, these effects are not excited, and when they are, a cure of the disease is not uniformly the result. The inflammation, carried to the requisite pitch to produce ulceration of the cyst, may only affect some points of it, and perhaps merely that portion which is next to the integuments. Every where else the inflammation may be very flight, and quite insufficient to cause ulceration and floughing of the deeper
part of the cyst. Then, external ulceration taking place, the tumour empties itself; and the part either heals up, with the exception of a fistulous opening; or things are brought into their original state by the formation of a perfect cicatrix, so that the encysted tumour makes its appearance again.

Some practitioners have thought that encysted tumours might be cured by the employment of irritating injections, like those so successfully used in the treatment of hydrocele. The experiments which have been made with them, however, have not generally answered; and, if we reflect upon the comparative state of things, it will appear that, in these cases, the object aimed at should not be the same. In the example of hydrocele, it is unnecessary to destroy the tunica vaginalis, and the obliteration of its cavity is all that is needed. Experience also proves, that, in consequence of a very mild degree of inflammation, the cavity of the tunica vaginalis is filled with lymph, which becomes organized, and connected with the adjacent membraneous surfaces. This suffices to render all exhalation for the future impossible. But encysted swellings have a peculiar organization, different from that of any originally formed parts. We have no reason for supposing, that any flight inflammation will make them pour out coagulating lymph that is capable of becoming vascular. They even seem so indolent to be thus affected, that nothing at all resembling it happens, unless the cause of the inflammation is kept up with considerable perseverance. The inflammation also, when it is excited, more readily produces mortification of the cyst, than the other kind of alteration. In fact, it is observed, that while some portions of the inflamed cyst become covered with fungous granulations, others mortify and separate in the form of sloughs. The whole of a cyst has not always the same structure, and affixed parts of it, for instance, are not likely to admit of that process, by which a hydrocele is usually cured. The hairs often growing in the cavity of an encysted tumour, must generally have their attachments destroyed by the inflammation following the use of an irritating injection, and they would then probably operate as extraneous substan ties.

These circumstances tend to shew, that the practice of making an incision into the swelling must be at all events preferable to that of employing irritating injections. By an incision, all the contents may be discharged, the whole cavity of the cyst exposed, and such applications constantly made as are calculated to keep up the requisite degree of inflammation. This method, also, gives the surgeon an opportunity of destroying particular portions of the cyst with caustic, if necessary. In this way, he is sometimes obliged to destroy the large fung, which frequently originate from the thickest parts of the cyst, after it has been opened and cauterized, or merely irritated by the dressings. Too often, however, the superficial use of caustic is insufficient to lessen the size of these fungous growths, and not adequate even to restrain their daily increase; while deep coagulations produce acute long-continued pain, fever, loss of sleep, and great irritation of the whole extent of the diseased. The train of symptoms, indeed, which the repeated free use of caustic may occasion, must seem still more alarming, when it is recollected that the cyst of the tumour sometimes becomes the seat of cancer; and that all the ravages of the latter disease in the ulcerated state may be the consequence. In this circumstance, the practitioner is obliged to have recourse to the extirpation of the swelling, and this sometimes a long while after the cyst has been opened, and not before the patient has suffered a long series of other painful, unavailing measures. Nor can these dangerous effects be avoided by opening the tumour with caustic instead of with a cutting instrument. The more certain inflammation of the cyst thus aimed at, is by no means sure of ensuing; and it will never follow, unless the caustic act strongly on the cyst. Besides, the action of caustic is too variable to justify the calculation, that its effects will reach to so precise depth, and always effectually destroy the cyst. See Delpech, Précis Élémentaire des Maladies Chir., tom. iii.

The inconveniences of opening an encysted tumour ought to make us give a decided preference to extirpating or amputating the whole of the swelling, whatever may be the nature of the cyst. Indeed, this method of treatment is superior to all others. The art of doing the operation skillfully, confits in detaching the tumour from the surrounding parts without wounding the cyst. If the latter accident occurs, the contents frequently flow out, the cyst collapses, and the continuance of the dissection is attended with more difficulty. It is a great point to remove every particle of the cyst; and hence it is satisfactory to take it out entirely, that is, without wounding it. When any portion remains behind, the wound will frequently not heal, in consequence of fungous granulations arising from the diseased part. Unless the swelling be large, a single incision through the skin is sufficient; but in other instances, it is advantageous to make two semicircular cuts in this manner, ; first, because it facilitates the removal of the tumour; and secondly, because it prevents a redundance of skin, which would take place if none were removed, and which would have the effect of seriously retarding the cicatrization of the wound. After the operation, the edges of the wound are to be brought together with flichting-plaster, and a compres and bandage applied.

The excision of encysted tumours, superficially situated, is mostly very easy, as the cyst is only lightly connected with the surrounding cellular membrane. But there may be more difficulty when the swellings have been in a previous state of inflammation; when they are very large, or when a portion of the cyst is deeply situated, or closely adherent to other parts. First Lines of Surgery, p. 144, edit. 3.

We must not quit the subject of encysted tumours, without making a few remarks on those of the scalp. The encysted tumours met with in this part, are situated between the integuments and the aponeurosis of the occipito-frontalis muscle. Their cysts are mostly of a hard, horny consistence, and filled with a pulpyaceous matter, being what are termed cases of atheroma. It is very common for such swellings to grow in large numbers. The intimate union between the aponeurosis and the skin causes the latter to be considerably stretched by the growth of tumours underneath it; but notwithstanding this effect, and that the integuments are also sometimes rendered very thin from the same cause, they are seldom altered in appearance, excepting occasionally their exhibiting a livid colour, which is a sign of their being about to ulcerate. When encysted tumours of the scalp have slowly attained an immense size, the skin covering them is distended in such a degree, that it is either quite bald, or at most only has a very few hairs upon it, so widely separated are the bulbs. It rarely happens that the pressure of the swelling produces an absorption of the part of the skull underneath the diseased; but examples of this kind have sometimes been observed.

Encysted tumours on the top of the head, even when they have acquired a considerable size, may be easily concealed by a hat, cap, or the head-dress; and, unless in a painful, inflamed, or ulcerated state, cause but little inconvenience. But when they are situated at the sides of the cranium, they render the wearing of hats, or any kind of head-dress, less comfortable.
TUMOURS.

convenient, and are much exposed to frequent causes of irritation, by which their enlargement, and even external ulceration, may be promoted.

The solidity and simple structure of the surrounding parts make the extirpation of these tumours very easy of accomplishment. A great portion of the skin which covers them, thin as it may be, ought to be shaved and laid down immediately upon the subjacent parts. It is only when the skin has been enormously dilated, that it becomes necessary to cut away the redundant quantity of it. No endeavour should ever be made to cure encysted swellings of the scalp by opening them, or applying caustic. The safest method is to remove them altogether with the knife. The surgeon need not be afraid of extending his incisions under the deepest part of the swelling; for if he be careful to cover the depressed part of the cranium with the skin which he is to lave, no exfoliations will generally follow. They do not necessarily follow, even when the pressure of the swelling has caused an absorption of some of the subjacent bone. Delpech is of opinion, that, as the scalp is very disposed to erythematous inflammation after wounds, surgeons ought not to cut out encysted tumours of that part, unless they produce serious inconvenience. On this point, however, we think differently; because we regard the objection to the operation, on the score of the danger of erysipelas from the wound, as exaggerated, and by no means sufficiently valid to justify leaving the tumour to itself. The disease would then continue to increase; the operation required hereafter would consequently be more serious; and, in the event of the tumour ulcerating, both more difficult in its execution, and more uncertain in its event.

In another part of the Cyclopaedia, the reader will find a few observations on the encysted tumours which frequently form upon the eye-lids. See EVILS, Encysted Tumours of. Of Fatty Tumours, Adipose Sarcoma, or Lipoma.—Fatty tumours, often termed also lipomata, or adipose, are formed by an accumulation of fat in a limited, and generally very circumferibered, extent of the cellular substance. The structure of a lipoma is absolutely the same as that of the adipose sub stance, such as it appears to be in those situations where fat naturally collects; with this difference, however, that the interstices of the cellular membrane, thus affected, are of considerable size, and obviously enlarged. The integuments, which are distended, and rendered much thinner, constitute a true fatty spread over the mass of fat, of which the tumour is composed; nothing appearing to be interposed between them and the swelling itself. There are some cases, where the partitions of the cellular sub stance, which separate the cavities in which the fatty matter is deposited, are thicker and more compact than in the natural fat; and when a section is made of these swellings, the exposed surface presents a marbled appearance of a yellow and white colour. Delpech remarks, that this species of lipoma is more disposed to become cancerous, than the common forms of it; but of this, very rational doubts may be entertained. In fact, our experience teaches us that true adipose tumours have as little tendency as any sort of swelling to change into true carcinoma, or that disease which is characterized by the peculiar alteration of structure, seen in only in cirrhotous affections.

Fatty swellings are mostly of an oblong pyramidal shape, and have a narrow pedicle, which is itself of a fatty texture; but sometimes they have a base, which is as broad as the whole mass of the tumour.

Lipomatous or fatty tumours are met with in persons of all ages; but they are most frequently observed in adults. The shoulders, the back, and the neck, are very common situations for these swellings. But their occurrence is so frequent, that there are few surgeons who have not had many opportunities of fering them in almost every region of the body. We once saw an adipose tumour which grew on the thigh, and after it had been removed by Mr. Cline, in St. Thomas's hospital, was found to weigh between fourteen and fifteen pounds. Sometimes adipose tumours are formed in parts where there is naturally but a small quantity of fat: thus Delpech has seen a fatty swelling formed in the labia pudendi, the structure of which is very different from fat. Sometimes adipose swellings are formed betwixt the peritoneum and the parietes of the abdomen, in which circumstance the tumours make their way outwards under the integuments, drawing along with them the part of the peritoneum to which they are attached. Such cases have been improperly named by the French surgeons 'hernia graffenens.'

The causes of the growth of adipose tumours are not known: the disease has been sometimes ascribed to blows, and other kinds of external violence; but we agree with M. Delpech in believing, that this doctrine is altogether incorrect and unfounded.

The shape and slow growth of adipose tumours might suffice to indicate their nature; but they present other characters, amongst which the consistence of the mass of the swelling deferves particular notice. These swellings are not elastic, but of a peculiar soft feel, resembling what is perceived on handling a bag filled with cotton. Their surface is unequal, but the irregularities which are distinguishable through the thin integuments have no firmness, and are obliterated by compression. These circumstances, however, are only strongly marked in such adipose tumours as have not yet acquired an immense size, and which remain free from every complication. When the swelling has become exceedingly large, its weight, its magnitude, its pressure on the surrounding vessels and integuments, materially obstruct the circulation; and an edema then taking place between the skin and adipose substance, the consistence of the latter part may appear to be increased. A manual examination, however, made by a surgeon of experience, will still detect the kind of softness which is peculiar to all fatty tumours, and discriminate it from the firmer feel of the cellular membrane immediately under the skin. Any previous attacks of inflammation may produce the same effect, and this even in a more remarkable degree. Such attacks are very common in those adipose swellings whose situation particularly exposes them to frequent causes of irritation. Thus, M. Delpech once saw a large lipoma growing in one of the labia pudendi, the incessant motion of which swelling, together with the friction of the thighs against it, and the irritation of the urine, had frequently made the skin inflame, and caused deep ulcerations in the sides of the tumour. The swelling was heavy and indurated; the irregularities of its surface were much firmer than usual; but in handling the mass attentively, the peculiar consistence of lipoma could be distinguished in the deeper part of the tumour, and be discriminated from the hardness of the integuments and cellular substance. Such induration is accidental; it seldom affects the whole of an adipose tumour; when it occurs, it is always confined to the layers of cellular membrane in which the adipose substance is lodged; it originates from repeated external irritation; and it should always be well discriminated from the hardnesses arising from a cancerous disease.

Adipose tumours, for the most part, grow in a regular, slow, and progressive manner; and their vessels are generally neither large nor numerous. Hence the removal of these swellings is attended with little danger of any serious degree.
of hemorrhage, and they are very easily separated from the surrounding parts. The detachment of the tumour, however, may be more difficult when there have been previous attacks of inflammation in the part. An adipose tumour, even when large, may continue a great many years without producing any material inconvenience, provided no complication attend the disease. The swelling may grow with more or less rapidity, or remain stationary; but it has never been observed to disappear spontaneously, and every means which has been hitherto tried with a view of dispersing it, has proved ineffectual. The only method of cure consists in cutting away every part of such a swelling, which ought to be done before the diseased mass is of very large size.

Of some other Kinds of Sarcomatous Tumours.—It is extremely difficult to name and describe, clearly and unobjectionably, all the different varieties of sarcoma. Mr. Abernethy has proposed naming them according to their anatomical structure, or their supposed resemblance in texture to particular organs. Thus he adopts the terms common vacuolar, or organized sarcoma; adipose sarcoma, which we have already described; pancreatic sarcoma; cystic sarcoma; mafloid or mammary sarcoma; tuberculated sarcoma; medullary sarcoma, &c.

Under the title of common vacuolar, or organized sarcoma, Mr. Abernethy comprehends all tumours which appear to be composed of the gelatinous part of the blood, rendered more or less vaculaiy by the growth of vessels through it, without having any distinguishing peculiarity of structure. Mr. Abernethy conceives that this kind of organization in tumours is the most simple, and perhaps, may always precede the other descriptions of structure. Vascular sarcoma not only makes its appearance as a tumour, which is altogether extraneous in regard to the original conformation of the body, it also enlarges natural parts, especially the teftis, mamma, and absurhent glands.

When this sort of swelling has attained a considerable size, the superficial veins become quite varicoe. If left to itself, the tumour generally grows till the skin is so distended, that it ulcerates and exposes the new-formed substance, which sloughs and falls out.

In this manner the disease might be got rid of; but such are the constitutional irritation attending it, and the fever and frightful appearance of the part, that the surgeon generally waits no longer, but removes the whole mass of the disease with his knife.

Pancreatic sarcoma is the name which Mr. Abernethy applies to those flothy tumours which resemble the pancreas in structure. The substance of which they consist is composed of irregularly-shaped masses, connected together by a fibrous kind of texture. This species of sarcoma is sometimes formed distinctly in the cellular substance; but most commonly occurs in the female breast, perhaps originating in the lymphatic glands. The tumour increases slowly, and generally has little tendency to inflame and suppurate. The morbid structure in question frequently takes place in the breast, a little above, and on that side of the nipple which is next to the arm. In general the disease is chronic, and does not involve the neighbouring aburhent glands. But, in a few instances, this species of sarcoma, when situated in the breast, deviates from its ordinary indolent nature, and occasions fever, lancinating pain, an inflammatory state of the integuments, and an adhesion of them to the tumour, the axillary glands also becoming enlarged. Pancreatic sarcoma is sometimes so irritable a disease, that Mr. Abernethy thinks it may frequently be considered as bad as cancer. When the glands in the axilla become affected, one generally first swells, and is extremely tender and painful; afterwards the pain abates, and it remains indurated; another then becomes affected, and runs through the same course.

Those sarcomatous tumours which contain cysts or cells, Mr. Abernethy distinguishes by the term cystic. The disease sometimes occurs as a distinct swelling; but it is more commonly observed in the tef-teis and ovary. The cysts are very vascular, so that they admit of being made quite red with an anatomical injection. They generally contain a serous fluid; but sometimes a yellow or yellowish fluid. Mr. Abernethy believes that this species of sarcoma is peculiarly intractable when situated in the tef-teis.

The mafloid or mammary sarcoma is so named from its resemblance to the mammary gland in structure. Mr. Abernethy has not frequently seen this kind of tumour, and his attention was called to the nature of the disease by a case, in which a swelling, partaking of the above structure, and about as large as an orange, was removed from the front of the thigh. The wound seemed at first difpofed to heal; but it afterwards degenerated into a malignant ulcer, which in about two months proved fatal. As this sort of tumour is gradually lost in the surrounding parts, which probably retain a disposition to assume a similar morbid alteration, Mr. Abernethy very judiciously recommends a more extensive removal of them than was practised in the foregoing example.

Tuberculated sarcoma is the name proposed by Mr. Abernethy for those flothy swellings which consist of an aggregation of small, roundish tumours, of various sizes and colours, connected together by a kind of cellular substance. This gentleman has principally seen the disease in the lymphatic glands of the neck. The tumours ulcerated, became painful, and ultimately destroyed the patients. Mr. Abernethy regards the tuberculated sarcoma as an incurable and fatal disease; though, fortunately, its occurrence is unfrequent.

Malignant sarcoma is the term applied by Mr. Abernethy to a malignant and dangerous kind of tumour, which resembles in its structure and appearance the medullary substance of the brain. It is often seen affecting the teftis, and has been termed the soft cancer of that part. Many surgeons consider this affection and the fungus hamatomas as the same: we do not therefore deem it necessary to offer here any remarks in addition to those already delivered on the latter disease in another article. See Fungus.

Treatment of Tumours.—Surgeons not only remain ignorant of those particular causes which produce the commencement of the growth of the various descriptions of fatty, fleshly, indolent tumours; they also know no effectual means by which the progress of the disease can be checked, and the patient freed from the inconveniences of continually bearing about with him a mass of redundant matter, which, in a chronic state, is both a deformity and an oppression; and in an inflamed or ulcerated state, is a source of severe pain, and even of fatal mischief. It has been conjectured that topical bleeding and cold applications would check the growth of indolent tumours; but experience teaches us to place no dependence upon the plan. Mercurial fuctions, electricity, blisters, and local stimulants, have also been repeatedly tried, with a view of exciting the action of the absorbents, and dispersing the swelling. Thefe methods, however, are not recommended by many examples of successes; and they are attended with some risk of irritating the tumour, without lessening it, in which case the disease sometimes changes from an indolent quiet form to an irritable state, in which it inflames, enlarges, ulcerates, emits fungi, and assumes a character as dangerous and intractable as that of cancer itself. Whenever a swelling is suppecsted of being either a mammary, mammary, or mafoidal tumour, to which it is very similar, much caution is necessary, and the case should be carefully examined and determined before any attempt is made to remove the disease.
TUMOURS.

tuberculated, or medullary sarcoma, it is particularly neccessary to abstain from doing any thing which may irritate the part.

Of the Operation of removing a diseased Breast, and Tumours in general.—The operation of cutting away a diseased breast, is done nearly in the same manner as the removal of tumours in general, and is indicated whenever the part is affected with an incurable disease, which admits, however, of being entirely removed with the knife. When the breast is affected with scirrhous, or ulcerated cancer, the imprudence of tampering with the diseafe cannot be too severely cenfured. Were the disorder unattended with a continual tendency to increase, some time might properly be dedicated to the trial of those internal remedies, and external applications, which have acquired any great merit for doing good in these unpromising cafes. But, unfortunately, by endeavouring to cure the disease by medicine, we only afford time for it to increase in magnitude, and, at length, to attain a condition, in which even the knife cannot be employed so as to take away the whole of the diseased parts. When the case is marked by the charactertic features of scirrhous, the sooner the tumour is cut out the better. There are also some malignant kinds of sarcoma to which the female breast is subject, which cannot be removed at too early a period after their nature is suspected or known. Indeed, though there is not equal urgency for the operation when the tumour is only an indolent, fimple, fatty, or farcomatous disease, yet as all these tumours are continually growing larger, and little fuccefs attends the attempt to disperse them, the practitioner should never devote much time to the trial of unavailing medicines and applications, and let the swelling attain a fize, which would require a formidable operation for its excision. Besides, every fimple, fclerous, or fatty tumour, is always accompanied with a certain hazard of changing into a malignant or cancerous one.

Certainly there are many swellings and indurations of the breast, which it would be highly injudicious and unnecessary to extirpate, because they generally admit of being diffcufled. Such are many tumours which are called seropulbrous, from their affecfing patients of this peculiar constitution: such are nearly all those indurations which remain after a fudden and general inflammatory enlargement of the mamma: such are most other tumours which acquire their full fize in a few days, attended with pain, redness, &c.: and of this kind, alfo, are the hardnesses in the breast, occasioned by the mammary absceses.

In the removal of all tumours, their malignant or cancerous nature makes it neceffary to obferve one important caution in the operation; viz., not to be fatisfied with cutting away the tumours juft at their circumference; but to take away also a considerable portion of the substance in which they lie, and with which they are surrounded. In cutting out a cancerous breast, if the operator were to be content with merely defcufcing out the diseafe, juft where his eyes and fïngers might equally lead him to fuppofe its boundary to be situated, there would still be left behind white fclerofed bands, which radiate from the tumour into the surrounding fat, and which would inevitablj occasion a relapse. In a vait proportion of the cafes alfo in which cancer of the breath unfortunately recurs after the operation, it is found that the skin is the part in which the diseafe makes its reappearance. Hence the great prudence of taking away a good deal of it in every cafe fculpccted to be a truly scirrhous or cancerous diseafe. This may also be done fo as not to prevent the important objects of uniting the wound by the firll intention, and covering the whole of its surface with found integuments. So frequently does cancer recur in the nipple, whenever it does recur any where, that many of the beft modern operators always make a point of removing this part in every infiance in which it is judged expedient to take away any portion of the skin at all. The surgeon, indeed, would be inexcufable, were he to neglect to take away fuch portion of the integuments covering scirrhous tumours, as is evidently affected, appearing to be difcoloured, puckered, and closely attached to the diseafed lump beneath. Nor fould any gland in the axilla, at all diseafed, nor any fibres of the pectoral mulfcle, in the fame frate, be ever left behind. There is no doubt that nothing has flamped operations for cancers with difrepute, to much as the neglect to make a free removal of the skin and parts surrounding every fide of the tumour. Hence the disease has frequently appeared to recur, when, in fact, it had never been thoroughly extirpated; the diseafe, though entirely a local affection, has been deemed a conftitutional one; and the operation frequently rejected as ineffectual and ufeftfs.

But strongly as we have urged the prudence, the neceffity of making a free removal of the skin covering, and of the parts surrounding every cancerous or malignant tumour, the fame plan may certainly be regarded as uueffary, and therefore uueficient, in most operations for the removal of fimple, fatty, or fclerous tumours. However, even in the latter cafes, when the swelling is very large, it is better to take away a portion of skin; for otherwife, after the excifion of the tumour, there would be a reundance of integuments, the cavity of which would only ferve for the lodgment of matter. The loofe fuperfuous skin, alfo, would lie in folds, and not apply itself evenly to the parts beneath, fo as to unite favourably by the firft intention; nor could the line of the cicatrix itself be arranged with fuch nice even- nefs as it might be, were a part of the redundant skin taken away at the time of operating.

The beft method of removing a diseafed breath is as follows: The patient is ufually placed in a fitting posture, well supported by pillows and affifants; but the operator would find it equally convenient, if not more fo, to remove the tumour with his patient in a recumbent position; and it certainly is better whenever the operation is likely to be long, or much blood to be loft, which circumstances are very apt to bring on fainting. We remember that Mr. Abernethy, in his lectures, used to recommend the latter plan; which, however, without the function of any great name, or authority, pleafes fuch obvious advantages, as will always entitle it to approbation. The arms should be confined back, by placing a flick between them and the body, by which means the fibres of the great pectoral mulfcle will be kept on the ftretch, a flate moft favourable for the defcufion of the tumour off its surface. The flick alfo prevents the patient from moving her arm about, and interrupting the progres of the operation.

When the tumour is not large, and only a firmarcula, free from malignancy, it will be quite unnecessary to remove any of the skin, and of course this need only be divided by one incifion, of a length proportionate to the tumour. The cut must be made with a common defcufing knife; and, as the division of the parts is chiefly accomplished with the part of the edge towards the point, the inftrument will be found to do its office best when the extremity of the edge is made of a convex shape, and this part of the blade is turned a little back, in the way in which defcufing knives are now often conftucted. The direftion of the incifion through the skin should be made according to the greatest diameter of the tumour to be removed, by which means it will be most easily defcufed out.

The
The direction of the incision is various with different practitioners; some making it perpendicular, others transverse. In general, the shape of the tumour must determine which is the best. In France, it has been said, that when the incision follows the second direction, it heals more expeditiously, because the skin is more extensible from above downward, than laterally, particularly towards the sternum, and consequently allows the sides of the wound the more readily to be placed in contact; and that the action of the pectoral muscles does not tend to separate the edges of the wound when it is perpendicular. On the other hand, it is allowed that the wound, made in the latter manner, is the most favourable for the escape of the discharge, if suppuration should occur. See Default par Bichat, tom. ii, p. 312.

The cut through the skin should always be somewhat longer than the tumour; and as it is, perhaps, the most painful part of the operation, and one attended with no danger whatever, it should be executed with the utmost celerity. Pain is certainly more or less be dreaded, according to its duration. The fear, however, of giving pain, has probably led many operators to err, by not making their first incision through the integuments large enough, the consequence of which has often been, that there was not room enough to get at the tumour so as to dissect it out with facility: the patient has been kept near an hour in the operating room, instead of five minutes, and the surgeon confounded by the spectators as awkward and tedious. It is clear, also, that, besides the great deal more blood lost from this error than would otherwise happen, the vessels being commonly not tied till all the cutting is finished, the avoidance of pain, that fear which led to the blunder, is not effected, and the patient suffers much more, and for a much longer time, in consequence of the embarrassment and obstacles in the way of the whole operation.

When the disease is of a circular, or malignant nature, the skin covering the tumour should at all events be in part removed. All that portion which is discoloured, puckered, tuberculated, or otherwise altered, should be taken away. Some m uns also be removed, in order to prevent a redundance, in all cafes in which the tumour is large. We have said too, that in cases of scirrhus and cancer of the breast, the nipple is considered a dangerous part to be left behind. For the purpose of removing the necessary portion of skin, the surgeon must obviously pursue a different mode from that above described; and instead of one straight incision, he is to make two semicircular ones, one immediately after the other, and which are to meet at their extremities. The size of these wounds must be determined by that of the disease to be removed, and by the quantity of skin which it is deemed prudent to take away; for the part which is included in the two semicircular cuts, is that which is not to be separated from the upper surface of the swelling, but taken away with it. The shape of the two cuts together may approach that either of a circle or oval, as the figure of the tumour itself may indicate as most convenient. The direction of the incisions is to be regulated by the same consideration.

In the above ways, the first division of the integuments is to be made in removing tumours of every description covered with skin. The fame principles and practice should prevail in all these operations; and, whether the swelling is the mamma, or any other diseased mass, whether situated on the chest, the back, the head, or extremities, the same considerations should always guide the operator's hand. The incision or incisions in the skin having been made, the next object is to detach every side of the tumour from its connections, and the separation of its base will then be the last and only thing remaining to be done. When the tumour is a scirrhus, or other malignant disease, the operator must not dissect close to the swelling, but make his incisions on each side, at a prudent distance from it, so as to be sure to remove with the diseased mass, every atom of morbid mischief in its vicinity. But when the tumour is only a mere fatty or other masses, perfectly free from malignancy, the cellular bands and vessels forming its connections may be divided close to its circumference. It is astonishing with what ease the operation is performed, and certain and the necessary division is made in the skin; they may almost be turned out with the fingers, without any cutting at all. When they have been inverted, however, they are then more adherent to the surrounding parts.

Thus we see, that the first stage of the operation of removing a tumour, is the division of the skin; the second, the separation of the swelling from the surrounding parts on every side; the third and last stage is the division of the parts to which its under surface, or base, is attached. The latter object should be accomplished by cutting regularly from above downward, till every part is divided.

It is a common thing to fee many operators constantly embarrased and confuted, whenever they have to remove a large tumour, on account of their having no particular method in their proceedings. They first cut a few fibres on one side, then on another; and turning the mass of diseased tumour now on this side, now on that, without any fixed design, they both prolong the operation very tediously, and prevent the by-handers a complete specimen of surgical awkwardness. On the contrary, when the operator divides the cutting part of the operation into the three methodical stages above recommended, in each of which there is a distinct object to be fulfilled, he proceeds with a confidence of knowing what he is about, and soon effects what is to be done, with equal expedition and adroitness.

Having taken out the tumour, the operator is immediately to tie such large vessels as may be pouring out their blood; indeed, when the removal of the swelling will necessarily occupy more than three or four minutes, it is better to tie all the large arteries as soon as they are divided, and then proceed with their division. This was the celebrated Deault's plan, and it is highly desirable of imitation in this country, not only because many subjects cannot afford to lose much blood, but also because the profuse effusion of this fluid keeps the operator from seeing what parts he is dividing.

The largest arteries being tied, the surgeon should not be immediately folicitous about tying every bleeding point which may be observed. Instead of this, let him employ a little time in examining every part of the surface of the wound, in order to ascertain that no portion of the swelling, no hardened lump, nor diseased fibres remain behind. Even if any part of the surface of the pectoral muscle should present a morbid feel or appearance, it must, on every account, be cut away. Also, if any of the axillary glands are diseased, the operator should now proceed to remove them. After the time spent in such measures, many of the small vessels, which bled just after the excision of the swelling, will now have stopped, the necessity for several ligatures will be done away, and of course the patient saved a great deal of pain, and more of the wound be likely to heal by the first intention.

Some information may be derived, respecting whether any of the tumour is left behind, by examining its surface, when taken out, and observing whether any part of them is cut off; for if it is, it may always be found in the corresponding part of the wound.
TUMOURS.

The axillary glands may always be taken out, without the least risk, if the plan pursued by Default in France, and Sir Charles Blicke, and other eminent surgeons in this country, be adopted. The method alluded to is, after dividing the skin covering the gland, and freeing the indurated part from its lateral connections, to tie its root, or base, with which it is connected, with the parts on the side towards the cavity of the axilla. Then the indurated gland itself may be safely cut off just above the ligature. Were the gland cut off in the first instance, the artery which supplies it with blood would be exceedingly difficult to tie, on account of its deep situation; and, by reason of its shortness and vicinity to the heart, it would bleed almost like a wound of the thoracic artery itself. In this way, there is also not the least hazard of injuring the latter vessel. It would be a great improvement in the mode of operating for the removal of these glands, if surgeons were always to make the patient lie down, with the arm placed in such a position as would let the light fall into the axilla. How much the steps of the operation would be facilitated in this way, we need not attempt to explain.

The above directions will enable a surgeon to remove tumours in general. They apply also in a great measure to encysted tumours; but in the latter cases, particular care must be taken not to wound the cyst, as it then collapses, and the diffusion of its contents is much more difficult. One half of each ligature is always to be cut off before dressing the wound. The edges of the incision are to be brought together with strips of adhesive plaster; and, before this can be done with ease, the flesh confining the arm must be removed, and the os brachii brought forward, so as to relax the pectoral muscle and integuments of the breast. No futubes should ever be employed, as they are useless, painful, and irritating. The wound being closed with sticking plaster, and a pledge of simple ceras, a compress of folded linen, or flannel, may be put over the dressings; these are to be secured with a broad piece of linen, which is to encircle the chest, be fastened with pins or stitches, and kept from slipping down by two tapes, one of which is to go from behind forward, over each shoulder, and be fastened to the upper part of the bandage both in front and behind. The arm on the same side as that on which the operation has been done, should be kept at rest in a sling; every motion of the limb must evidently disturb the wound by putting the great pectoral muscles in motion, or rendering its fibres sometimes tense, sometimes relaxed.

In the article Surgery, we have adverted to the plan of cutting off both ends of the ligatures applied to the arteries, with a view of lessening the quantity of extraneous subfusitate in the wound, and rendering union by the first intention more probable. This method has been tried by Mr. Lawrence after operations on the breast, and also by M. Roux and professor Delpech in France, who all make favourable reports of the practice.

The removal of tumours from the neck is frequently an operation of delicacy and difficulty, especially when the exact attachments and depth of the swellings are not precisely known. The many large arteries in this part of the body, and its being the situation of the carotid artery, and internal jugular vein, are considerations which ought to deter every surgeon who is not an anatomist, from venturing to cut away swellings from the neck, particularly such as have bales extending more or less deeply, and not very movable. Unfortunately for the man who is deficient in anatomical knowledge, the neck is as common a situation for tumours requiring the ufe of the knife, as any part which can be specified.

Vol. XXXVI.

One of the boldest operations, for the removal of a tumour from the neck, was that lately performed by Mr. William Goodlad, surgeon at Burry, in Lancashire, and recorded in the seventh volume of the Medico-Chirurgical Transactions, p. 112. In order to do away the danger of hemorrhage from arteries, this gentleman began with tying the trunk of the carotid artery; some conception of the nature of the whole proceeding may be formed from the view which the wound presented after the entire swelling had been removed. "The whole ferior-malloid muscle was exposed, and its fibres dissected clean, except about half an inch from its insertion into the clavicle. The wound extended backwards from behind the mastoid process to the trachea anteriorly, but became narrowed in the direction of the muscle at the lower part of the neck. The submaxillary gland was exposed, and about one-fifth of its substance, not appearing healthy, was removed. The digastric and the greater part of the mylo-hyoides were exposed, the ramus of the jaw was only covered by periorientum, except where covered by the masseter muscle, part of which, not appearing healthy, was dissected away. The whole of the condyloid process of that bone was laid bare in the same manner, and behind it the pterygoideal muscles were also exposed. The membrane of the cheek was only covered by a cellular substance, which did not appear healthy; but sufficient skin was freed to cover the zygoma. The parotid gland was entirely removed." This, which is one of the boldest operations on record, proved successful, the wound having completely healed in ten weeks, and no recurrence of the tumour having followed. See Abernethy's Classification of Tumours. Delpche Précis Elémentaire des Maladies réputées Chirurgicales, tom. iii. Cooper's Dictionary of Practical Surgery. Medico-Chirurgical Trans. vol. vii. pt. 1, &c.

TUMOUR, among Animals, is a preternatural swelling or enlargement in any part, arising either from an external injury, or an internal cause. Tumours in them are of several different kinds, according to the nature of the causes.

Where tumours or swellings are caused by external accidents, such as blows, bruises, and other such means, they should at first be treated with refrangible applications; such as having the parts bathed frequently with warm vinegar or verjus; and where they will admit of bandage, a flannel wetted with the same should be rolled or laid on, and kept in that situation. When by this method the tumour or swelling does not give way and subside, a poultice made with red-wine lees, strong-beer grounds, and oatmeal, or with vinegar, oil, and oatmeal, should be applied, especially when on the legs; either of which applications may be used and continued twice a day after bathing the parts in the above manner, until the swelling abates, when, in order to wholly disperse them, the vinegar should be changed for camphorated spirits of wine; to four ounces of which, one of spirit of fal ammoniac may be added; or they may be bathed with a mixture of two ounces of crude fal ammoniac boiled in a quart of chamber-sky, twice a day, and cloths dipped in the same be put on them. Fomentations, too, made by boiling wormwood, bay-leaves, and rosemary, with a proper quantity of spirits, are not unfrequently of use in a high degree.

However, in bruises where there may be extravasated blood, which is not taken up or dispersed by these means, the shortest and most convenient way is to open the face, and to let out the gruminous blood.

The critical tumours or swellings in horses or other animals, which terminate fevers, or other diseases, should by no means be dispersed, except, when in the hooves, they fall
upon the pattern or coffin-joint, fo as to endanger them; in which cafes the ditficient fomentation may be applied three or four times a day, and a cloth or flannel frequently wrung out of the fame may be bound on the parts.

But when the swellings fix themselves under the jaws, behind the ears, on the poll, the withers, or in the groin, sheath, or other parts of the hoie, or any other animal, they should be encouraged and brought forward by ripening poultices, wherever they can be applied: oatmeal boiled foft with milk, to which a proper quantity of oil and laird is added, may answer this purpose; or the poultice compounded of linseed-meal, as used in other cafes: these should be applied twice a day, until the matter is perceived to fluxuate, by the feel, under the finger, when it should be let out; for which purpose a knife or flrong lancet should be used, making an opening the whole length of the tumour, where it can be safely done, as nothing contributes fo much to a kind healing of the parts, as the matter having a free discharge, and the opening being sufficiently large to drefs it to the very bottom.

After this, pledges of lint or tow, spread thinly with black or yellow bafiicon, or the wound ointment, and dipped in the fame, melted down with a fifth part of oil of turpentine, should be laid to the bottom of the fore, and the whole filled up in a very light manner with the fame, without any fort of stuffing. It may be drefsed in this way once or twice a day, if the discharge be great, until a proper digestion be brought on, when it should be changed for pledges spread with the ointment with red precipitate, ufed in the fame manner. If the fore should not digest kindly, but look pale, and discharge a thin watery fluid, it should be fomented as often as it is dressed with the above fomentation, and the flrong-beer poultice be applied over the drefsing, continuing the fame until the matter grows thick, and the fore has a florid appearance.

There are other indolent tumours fometimes occurring in animals, but which are noticed under their proper heads.

Tumours, Mooy, in Agriculture, a term applied to the small hilly spots or swells of boggy plots which are formed on the banks of hanging flopes, or dippers over flatter surfaces, in particular cafes and situations. They may be formed in various ways, as in the manner of quickfands, by the waters which fall in their immediate vicinities, but which, to produce certain defects of the wet kind in the lands, find a receptacle sufficient to give the affected tumour parts a conflant supply of moisture, or what is enough for giving the bog plants that take root upon them fertility and support. Thus, fuch ripening grounds as are formed of open, porous, or freely conducting materials, having the lower borders of them imperfectly covered with an impermeable foil, are peculiarly liable to be affected with this fort of tumour defect. They are likewife capable of being caused by maffes of impenetrable matters, which are lodged on the fides of the declivities, or at the feet of them; also by internal wetness, defending through the land in partial channels that lead it to the surface; and by the fame fort of wetness when confined beneath an impermeable foil, but which is defective, and by reason of the weight thereof above it, admits of the confined moisture rising through veins of the fandy kind, or other conducting substances and passages to the surface where these forts of tumours are produced.

Wherever lands are troubled with these kinds of tumours, which is not unfrequently the cafe, they are to be removed by drawing away the wetness in proper methods, and the suitable manuring, retinking, and managing of the ground, by which means they may often be converted into good fwalk land. See Mooy and Waste-Land.

TUMPACH, in Geography, a town of Bavaria, in the Upper Palatinate; 32 miles E.N.E. of Nuremberg.

TUMPING, in Agriculture, a term applied to the work of moulding up teafel crops, which is done in a clofe round manner, in order to make them "haddle" out, or throw forth fide-flouts, as it is called. It often answers as a kind of fence.

TUMUCHANAIG, in Geography, a town of Hindooftan, in Madura; 30 miles S.W. of Madura.

TUN, a town of Sweden, in Weft Gothland; 24 miles W. of Skara.—Alto, a town of Perfia; in Khoraffan; 25 miles E.N.E. of Paftn.

Tun, or Ton, originally signifies a large vefSEL or cafe, of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and ufed to put up several kinds of merchandizes in, for their better carriage; as brandy, oil, fluger, flkus, hats, &c.

Some derive the word from autumnus, in regard it is then tuns are most needed. Du-Cange deduces it from tunna or tunna, words ufed in the cafe Latin for the fame thing; whence alsu tunnae, to tun.

The term is alsu ufed for certain vefSels of extraordinary bignefs, serving to keep wine in for several years. In Germany, there are many which are scarcely ever emptied: the Heidelberg tun is famous. The tun we frequently, though improperly, call a hoghead.

Tun, or Ton, is alsu a certain meafure for liquids; as wine, oil, &c.

The English tun of wine contains 2 pipes, or 4 hogheads, or 252 gallons. See Measures, Table XXI.

The standard gauge for foreign wines at the Cutlom-houfe of London is as follows: the pipe of Port is 138 gallons; of Lisbon, 140; of Madeira, 110; of Barcelona, 120; of Vidouia, 120. The butt of sherry is 130 gallons, and of mountain, 120. The hoghead of claret is 58 gallons, and of teut, 63. The awm of hock is 36 gallons. The gallon ufed here is feven inches in diameter and fix inches deep. The tun of animal oil is 252 gallons, and of vegetable oil 236 gallons.

The tun of Amsterdam contains fix ams or awms; the awm contains 4 ankers, 8 fekeans, 21 vierelts, 64 floops, 128 mingels, 236 pints, or 1024 mufes; and holds 8966 Dutch, 7705 French, or 9351 English cubic inches, or about 461 English wine gallons. The tun of beer contains 128 mingels, like the above. A tun of corn is 1.5 munden, or 1.5 facks, and holds 5 fceepels, 20 vierdevats, or 160 koops: 27 munden are equal to a half of corn, which contains 173208 Dutch cubic inches, 147120 French ditto, or 178540 English.

A tun of Leyden butter weighs 320 lbs.; and a Vierendel 80 lbs.; but the Vierendel of common Holland's butter weighs 84 lbs. A Frieland tun is 328 lbs.; and a Maffenbrook tun, 400 lbs.

At Bayonne, a muid or hoghead of wine contains 320 French pints, or about 76\(\frac{1}{2}\) English gallons; and 4 muids at Bayonne are equal to 5 at Bourdeaux. The pipe of brandy holds 80 velts, anfwerine to about 156 English gallons.

At Bourdeaux, a tonneau of wine contains 4 barriques or hogheads, equal to 50 fekeans of Amsterdam = 250 flhuben of Hamburg = 245 English gallons; and weighs with the wood about 2000 lbs. of Bourdeaux. The barrique contains 110 potts, or 32 lbs. Brandy is contained in casks of 50 velts, more or less; but it is held by the barrique of 32 lbs, or about 60 English gallons: 5 velts proof of Bourdeaux make 4 velts proof, by which it is told in Lon-

don.
At Cognac it is sold by the 27 vels; and 11 vels proof of Cognac make 10 vels proof, by which it is sold in London. A tun of butter, great measure, at Bremen, is reckoned at 300 lbs., but a tun of small measure at 220 lbs.; 100 lbs. of Bremen being equal to 110 lbs. avoirdupois. A fuder of wine contains 6 ohms; an ohm, 20 viertels = 45 flugens = 180 quarters = 720 mingels; 45 flugens answering to 38 English gallons. Brandy is sold by the 30 viertels. A tonne of beer contains 48 flugens = 192 quarters. A hogshead of train oil contains 2 tonnes, or flackens = 192 mingels.

At Brunswick, a fuder of wine contains 4 oxhofts, or 6 aams; an aam = 40 flugens = 160 quarters = 320 nosells. A fass of beer contains 4 tonnes; a tonne 27 flugens; and 63 flugens = 61 English gallons.

At Danzig, a tonne or barrel of butter is = 16 lipfonds = 256 lbs. A lat of beer contains 6 fasses = 12 tonnes or barrels = 1080 flods; the beer-tol being = 141 English cubic inches. A tonne or barrel of herrings contains 13 whale, each of 80 herrings; a lat of herrings, Luneburg falt, honey, pitch, tar, ashes, &c. contains 12 tonnes or barrels; and a lat of French, Scotch, or Spanish falt, when lying together, contains 18 tonnes, and when in separate tonnes, only 16.

In Denmark, the tonneau of French wine is reckoned for 4 hogheads, or 24 ankers; the pipe of Spanish and Portugal wine for 2 hogheads, or 12 ankers; 30 Spanish arrobas, or 22 Portuguese almuds of wine, for 1 regular pipe; the pipe of French brandy for 6 ankers; the poineon ditto for 9 ankers; the tiercon ditto for 4 ankers.

At Embden, corn is sold in tonnes of 4 verps, 8 scheffels, or 144 kruefen: 15 tonnes, or 60 verps, make 1 lat, answering to 125 English quarters.

In France, by the old system, a tonneau of Orleans contains 2 muids of Paris, the muid of wine at Paris being = 70 lbs. almudes: — a tonneau of Bourdeaux = 4 barriques, each of 216 pints of Paris, or 53 lbs. English gallons.

In most parts of Germany, a lat of lime, tar, pitch, train oil, butter, &c. is 12 tonnes or calves; a lat of herrings is 12 tonnes, each tonne containing about 800. See Tonneau.

At Hamburgh, a tonne of butter, small measure, is 224 lbs.; ditto, great measure, 280 lbs.: a pipe of oil is 820 lbs.; and a small tonne of green soap is 60 lbs.: a tonne of beer contains 48 flugens; a small ditto, 32 flugens; a quart of train oil contains 2 tonnes or 64 flugens, and is reckoned at 224 lbs. net weight.

In Hanover, a tonne or barrel of honey contains 25½ flugens, and weighs 300 lbs.

In Holstein, the measure for corn is the same as that of Copenhagen; viz. the tonne of 8 scheffels, or 32 viertels, 100 of which tonnes yield about 49 English quarters. A tonne of beer contains 128 quarters, or 25 English beer-gallons.

For the value of the tonne at Konigsberg in Prussia, see Tonneau.

At Libon, 13½ quintals make a ton; and each quintal contains 4 arrobas; the arroba 32 lbs., the pound of Libon weighing 70½ lbs. grains English Troy weight; so that 84 lbs. of Libon are equal to 84 lbs. of avoirdupois weight. The standard gauge, at the Custom-house of London, of a pipe of Libon, is (as above-mentioned) 140 gallons, and this pipe is reckoned at 31 almudes, and the almude at 4½ English gallons nearly.

At Nantes, in France, a tonneau of wine contains 2 pipes; a pipe, 2 barriques or hogsheads, or 240 pots; the pot holding 2 Paris pints, and the barrique containing 59½ English gallons, and a poineon of wine about 54½ ditto.

At Narva, in Livonia, a lat of corn contains 24 tonnes, and a tonne 4 viertels, or 32 kapps: 26 tonnes of Narva = 15 English quarters nearly: the lat of French and Spanish falt is reckoned at 18 tonnes, each of 34 kapps. The alm of wine contains 4 ankers, and a pipe of Spanish wine is reckoned at 10 ankers; of Alicante and Portuguese wine at 13 ankers, Hamburgh measure; a fass of beer or brandy contains 128 flo's, and 44 flo's answer to about 15 English gallons.

At Oporto, the ton is = 2 pipes = 50 almudes = 2 potes = 12 canadas = 24 quartilhos = 8 meios. At Libon, both wine and oil are sold by the pipe of 26 almudes; but the pipe of Libon wine sent to England contains about 31 almudes, and its standard gauge is 140 gallons; and therefore the Libon almude is reckoned at 4½ English gallons. At Oporto, the pipe is divided into 21 almudes, but this almude and its subdivisions are 4½ per cent. greater than those of Libon. Thus the standard gauge of a pipe of port, at the Custom-house of London, is 158 gallons, which gives the almude of Oporto equal to 6 English gallons and 5 pints nearly. Ships are measured by the ton, being a cylinder 6 feet high and 3½ feet in diameter, which gives the contents 5½ cubic feet nearly. The proportion between the almude of Libon and the almude of Oporto is variously given by different authors; some make it = 30 per cent., others 25, and others from 25 to 40; but the real proportion, says Dr. Kelly, is 49½ per cent.; but in the common course of business, 2 almudes of Oporto are reckoned equal to 3 of Libon.

At Peroum, in Livonia, a lat of corn contains 24 tonnes, the lat containing about 86½ Wincheister buflens, or 16 lafs = 173 English quarters. But a lat of linseed is reckoned at 12 tonnes, and a lat of salt at 18 tonnes.

At Revel, in Livonia, a lat of corn contains 24 tonnes, and a tonne of salt is 4 lafs: 19 tonnes of corn in Revel are = 8 English quarters.

At Riga, a lat of rye contains 22½ tonnes; a lat of wheat or barley, 24 tonnes; a lat of oats, malt, or pease, 30 tonnes: 24 tonnes being = 48 lafs, and 56 lafs of Riga = 13 English quarters.

At Stralsund, a lat of corn contains 8 drams = 32 tonnes = 96 scheffels: 46 scheffels contain 51 English buflens nearly, or 46 drams = 76½ English quarters. Kelly's Univ. Cambilt. paffim.

The great ton or Rhein wine-vels of Heidelberg, made in 1343, contained 672 urnz, of 4½ English gallons each; being in all 2690 English gallons, or about 24 hogheads, or 21 pipes of wine.

Tun is also a certain weight, by which the burden of ships, &c. is estimated.

The sea tun is computed to weigh 2000 lbs., or 20 quintals or hundred weight (amounting to 2440 lbs. avoirdupois); so that when we say a vesell carries 200 tuns, we mean it is able to carry 200 times the weight of 2000 lbs.; i.e. 400,000 lbs.: it being found by a curious observation, that the sea-water, whose room the vesell fills when full loaded, weighs so much.

To find the burden and capacity of a ship, they measure the hole or place where she is loaded; allowing 42 cubic feet to the sea tun. See Burden, and Tonnage under Ship-building.

The price of freight, or carriage of merceintries, is ordinarily settled on the foot of the sea tun; and yet, though the tun is regularly 20 cwt., there is some difference made in it. Upon account of the cumberfomness or bulk of the commodities, the space they take up, or the like. See Freight.

Accordingly, at Bourdeaux, 4 barriques of wine, and also of
of vinegar, honey, and turpentine, are held a tun; 5 of brandy, 3 of syrup, 20 bushels of chestnuts, and the like of corn, beans, linseed, walnuts, &c.; 5 bales (each of 100 lbs.) of cork, 5 bales (each of 100 lbs.) of feathers and skins, and 8 of paper; 10 cubic feet of marble, 20 quintals of iron in bars, or lead in pigs, 3 bales of hemp (each of 200 lbs.), 20 quintals, or 150 rolls of tobacco.

At Stettin, the freight of ships is generally valued by the Dutch ship list, 5 of which are equal to 4 lists of Stettin; and 4000 lbs. of iron, and other heavy goods, 2000 lbs. of lighter goods, such as hemp and flax, 500 sheffels of corn, 13 calls of herrings, 8 hogheads of wine, 5 schocks (each of 60 pieces) of pipe-claves, 7 schocks of hoghead-flavels, 9 schocks of barrel-flavels, 65 cubic feet of oak-timber, or 70 cubic feet of fir-timber, are reckoned for a Dutch list.

A tun or load of timber is forty solid feet, if the timber be round; if it be hewed or square, fifty-four.

Tuns, in Natural History, a family of univalves. See SHELLS AND CONCHOLOGY.

Tun, Ton, in the ends of words or names of places, signifies a town, village, or dwelling-place: from the Saxons, tun, feper, wallum, villa, vico, oppidum; and this from don, or don, a hill, where they formerly built towns.

Tun-Grees, a name anciently used for a reeve or bailiff, qui in villa, et & que dicimus manerius, domini perfanum suflinens, ejusque vice omnia dispensat & moderat. Spelman.

Tun-Hoof, in Botany. See GLECHOMA.

Tuna, in Botany, slightly altered by Dillenius from the South-American or West-Indian appellation of the fame plants, Tuna, Tunal, or Tunas, is retained by him for the tribe of American Figs, named Opuntia by other modern botanists. He contends, with great probability, that Opuntia of the ancients must be something very different. Linnaeus refers Tuna to Cactus; see that article.

Tuna, in Geography, a small island in lake Menzaeh; 8 miles S.E. of Tennis.—Alfo, a sea-port of Egypt, in the Red Sea. The entrance is between rocks, and within the greater part is filled with hillocks and rocks, which make the harbour small. On the north side is a tongue of land, which forms a good defence against the north-west wind; 52 miles S.S.E. of Coefer.—Alfo, a town of Sweden, in Hel Lingland; 3 miles N. of Hudwickfwall.—Alfo, a town of Sweden, in the province of Smaland; 56 miles N. of Calmar.—Alfo, a town of Norway, on the Glaumnen; 2 miles N.N.E. of Frederickfadt.—Alfo, a town of Arabia, in the province of Hedsjaa; 280 miles E. of Medma.—Alfo, a small island and village of Egypt, in the Tennis lake; 21 miles W.N.W. of Tineh.—Alfo, a town of Sweden, in Dalecarlia; 10 miles S. of Fahlun.

TUNAL, a town of Mexico, in New Biscay; 74 miles N.N.W. of Durango.

TUNALLUS, in Ichthyology, a name given by Albertus, and some others, to the greyling, or umber.

TUNB, in Geography. See Tunb.

TUNBATE, a town of Brifal, in the government of St. Paul; 65 miles N.N.E. of St. Paul.

TUNBO, a town of Sweden, in Sodermanland; 50 miles W. of Stockholm.

TUNBRIDGE, or Tunbridge, a market-town in the late of Aylesford, and county of Kent, England; is situated in an extensive tract called the Lowey-of-Tunbrige, and is distant 13 miles W.S.W. from Maidstone, and 50 miles S.E. from London. The term Lowey is derived from the Norman French, and signifies an exempt jurisdiction round the castle or chief manion to which it appertained. In the Domesday book this dirfrict was included under the name of Hallow, but no mention is made of a castle; whence it seems probable it was not erected when that survey was made; though it certainly was very shortly afterwards. It was built by Richard Fitz-Gilbert, afterwards earl of Clare; and under the protection of this fortress the town grew up, and gave its own name to the castle, which name appears to have been derived from the bridges over the different streams of the Medway, which flow on the south side of the town. Of these streams, which have each a bridge, and are five in number, the outermost was anciently the principal, as the northern now is; though the latter was originally formed to supply the innermost of the castle.

This fortress has been at different periods the scene of war and of fertility. Gilbert Rufus, who posed it in the reign of Henry III., joining the rebellious barons, was besieged by prince Edward, when the garrison burnt the town to prevent its being useful to that prince, who, however, took the castle: but Gilbert having joined the royal standard, it was restored to him. Here he entertained Edward, then become his sovereign, in a splendid manner for many days, on his return from Palestine. Prince Edward, afterwards Edward II., also made Tunbridge his temporary residence. In the next reign, the castle and manor passed by marriage to Ralph, earl of Stafford, whose descendants rode to a rank that eclipsed all other subjests, having five earldoms vested in them, and being at length advanced to ducal honours. In the reign of Henry VIII., the castle became forfeited to the crown by the attainer of Edward, duke of Buckingham. Queen Elizabeth granted the lordship and castle to her cousin Henry Carey, lord Hunsdon, from whom they descended to the Berkley's; having paffed through various possiflors, they are now the property of the Woodgates of Summerhill. The remains of the castle fland on the south-west fide of the town, but are principally confined to an entrance-gateway, flanked by round towers, and tolerably perfect, (probably rebuilt in the 14th century,) and the artificial mount on which the keep ftood. The castle was enwomed by three moats, within the outermoif of which the ancient town was chiefly confined. At a fhort diftanice was a priory of Austin canons, founded by Richard de Clare, firft earl of Hertford, about the end of the reign of Henry I. The buildings were all defroyed by fire in 1531; but were foon afterwards rebuilt. This was one of the houses fuppofed in 1525, to endow Wolley's intended colleges at Ipfwich and Oxford. From the foundations, yet visible, this priory appears to have been very extenfive: but only a few fragments now remain, besides the refefory or hall, which is used as a barn.

The town of Tunbridge principally confifts of one long and wide street, kept remarkably clean, and containing many repectable houses. At the entrance from London is a flone caufeway, the gift of John Wilford, citizen of London, in 1528. The principal bridge was erected in 1775, at the expense of 1100l., from a defign by Mr. Milne: near it is a wharf for the reception of the timber brought hither from the Weald, and afterwards fent down the Medway. The church, which is a fpacious fabric, was new pewed and orna mented, with a bequeath of 500l., made by the late John Hooker, esq. It contains fome good monuments of various families. Wever mentions "the portraiture of lord Hugh Stafford, kneeling in his coate-armour, and his bow-bearer, Thomas Bradlaine, by him," as remaining in his time in the north window. Many bequeaths have been made by different persons for the use of the poor inhabitants of this diocfe; but the principal charitable foundations is the free grammar-school, a capacious edifice at the north end of the town, which was founded and endowed by sir Andrew Judde, a native of
of Tunbridge, and lord-mayor of London in the fifth year of Edward VI. He died in 1558; and by his will directed that certain lands, of the annual value of £6l. or £6., and situated in various parishes in London, should be veiled in the company of skinners of London, for the perpetual maintenance of this school, for the free education of the boys inhabiting this town and the parts adjacent. Sir Thomas Smith, who married Sir Andrew’s daughter, considerably increased the endowments, and founded six stipends to the university; and several others were endowed by different persons. The skinners’ company, who are the governors, visit this school every year in May, attended, as the statutes direct, by some eminent clergyman, who is required to examine into the progress made by the different classes. The examination is conducted with much ceremony; and honorary rewards are distributed to the best scholars. The malts have, in general, been men of eminent abilities. The learned Dr. Viceimus Knox, well known for his literary productions, succeeded his father in this office in 1778. Though the annual income arising from the respective endowments of this school is very great, the number of boys educated on the foundation is very few: which, among other instances, points out the necessity of a parliamentary revision of our ancient charitable establishments. Immediately opposite the school is the seat of George Children, esq., to whose respectable family a very large and valuable tract of land belongs in this vicinity. The population of Tunbridge, as ascertained by the act of the year 1811, amounted to 5932, the number of houses to 958. Four fairs are held annually, and a market weekly on Friday. The adjacent roads have of late years been much improved, and that leading from the town to the Wells particularly so, by a laborious excavation on Quarry-Hill, by which the former steep ascent over it has been reduced to a very easy draught. It appears, from the “Notitia Parliamentaria,” that two members were returned in the 23d year of Edward I. for the borough of Tonbridge. About a mile and a half to the south-east of Tunbridge is Summerhill, an ancient and celebrated seat, now the property of William Woodgate, esq. The venerable mansion was erected by Richard de Burgh, earl of St. Albans, at a vast expense, in the reign of James I; of the style of building in whose day it forms a complete specimen; though its external appearance has, in some respects, been injured by injudicious alterations. It is a very extensive and interesting structure, and stands on a commanding eminence amidst romantic scenery.

On Quarry-Hill, about a mile and a half from Tunbridge, on the road to the Wells, is the seat of James Burton, esq. recently erected with the appropriate materials of the country, as the fragment of a castle, but replete with modern conveniences. Within a mile, on the same road, is Bounds Park and House, now the property of the earl of Darlington. The demesne surrounds the park, and consists of about a thousand acres of well-wooded land.—Hasted’s History of Kent, vol. ii. Beauties of England and Wales, vol. viii. Kent; by E. W. Brayley.

TUNBRIDGE WELLS, a hamlet in the west half hundred of Washlingstone, lathe of Aylesford, and county of Kent, England; consists of several villages within five or six miles from the town of Tunbridge, and situated in the three parishes of Tunbridge, Frant, and Speldhurst, at the distance of 18 miles S.W. from Maidstone, and 35 miles S.E. by S. from London. The principal villages are, Mount-Ephraim, Mount-Pleasant, Mount-Sion, and the Wells, properly so called. The springs, to which this neighbourhood is wholly indebted for its origin, rise in the parish of Speldhurst, and were accidentally discovered in the reign of James I. (See Tunbridge Waters.) Their fabulous quality being soon ascertained, wells were sunk, paved with stone, and lined with copper, in a triangular form. Hither came the afflicted, and returned healthy: but as no accommodations were nearer than the town of Tunbridge, the number was few. Henrietta Maria, queen of Charles I., being much indisposed after the birth of prince Charles, ilaid here five weeks; but as no house was near, she and her suite remained under tents pitched upon Bishop’s-Down. The splendid court formed a fine contrast to the country, every where rude, and in the unadorned attire of nature. In honour of her majesty, the Wells changed their name from Frant to that of Queen Mary’s Wells, which afterwards gave place to Tunbridge-Wells. During the civil war the Wells were neglected, and almost forgotten; but at the Restoration, recovered their former fame. Their celebrity was greatly increased in 1664, by queen Catherine being recommended to drink the waters after a dangerous illness. She continued here about two months, in great splendour: hence may be dated an assembly-room, bowling-green, and other appropriate places, at Ruthall; and another bowling-green and a coffee-house at Southborough. The surrounding country was spotted with neat rural habitations; till whin, and some alteration between the lord of the manor and the tenants, varied the scene. Ruthall was now deserted for Mount-Ephraim, and that for Southborough, which was soon eclipsed by Mount-Sion. At this changeful era, many of the houses were wheeled on sledges from one frite to another, as the caprice or interef of the owners dictated. The town of Tunbridge was now left to its original quiet; for the Wells became a complete village, with houses sufficient to accommodate all the visitors. A chapel and a school were erected by subscription, and the former being found too small for the increasing congregation, was enlarged a few years afterwards. This chapel stands in the three parishes; the pulpit is in Speldhurst, the altar in Tunbridge, and the vestry in Frant. A Presbyterian and also a Methodist meeting-house have been since built. During the last century, the buildings have gradually increased; and many persons of rank and respectability have houses for constant or occasional residence. Trade is carried on similar to that of the Spa in Germany, and consists chiefly in the manufacture of a variety of articles in wood of various kinds: the goods are well known by the name of Tunbridge-ware, as tea-chests, dressingboxes, snuff-boxes, punch-ladles, children’s toys, and many other articles. The air of this district is very pure and salubrious, and probably aids the efficacy of the waters, which are of the chalybeate kind, and nearly of equal strength to those of the German Spas. They are considered to be of great use in removing complaints arising from sedentary occupations, weak digestion, and nervous and chronical disorders. During the last and present reigns, Tunbridge-Wells has been frequently visited by different branches of the royal family. The Wells, properly so called, form the centre of the place; near which are the markets, medicinal water, a chalybeate spring, and public parades, called the Upper and Lower Walks; the Upper Walk was formerly paved with brick, but in 1793 with Purbeck stone, at an expense of £100; the other is unpaved, and used chiefly by country people and servants. On the right of the paved walk, in the way from the Wells, are the assembly-room, library, coffee-house, and shops with toys for Tunbridge-ware, milliners, and different kinds of toys. A portico extends the whole length of the parade, supported by Tunick pillars, where the company occasionally
occasionally walk. On Mount-Sion, Mount-Pleasant, Mount-Ephraim, and Bishop's-Down, are dispersed some
neat villas. That of the late celebrated writer, Richard
Cumberland, esq., is on Mount-Sion, and was his retreat
for many years.

The High Rocks, about a mile and a half south-westward
from the Wells, are much celebrated, and certainly form a
very romantic and striking picture. This spot is said to
have been first brought into notice by James II., who,
when duke of York, came hither with his duchesses and his
two daughters, afterwards the queens Mary and Anne.—
Burr's History of Tunbridge-Wells, 8vo. 1766. Beauties
of England and Wales, vol. viii. Kent; by E. W.
Brayley.

TUNBIDGE, a township of Vermont, in the county of
Orange, containing 1640 inhabitants; 20 miles N.N.W.
of Hanover.

TUNE, the title of a short melody, or series of notes, in
some specific measure. If vocal, it is a ballad; if merely
infrumental, it is a country-dance, a jig, or a hornpipe.
Our parochial psalmody confiits of psalm tunes. The
music of the "Beggar's Opera" is a medley of tunes se-
lected from the streets of all nations, that are never honoured
with the name of airs. See BALLAD.

Scotch, Irish, and Welsh fongs and dances, are called
national tunes. The tonadillas and lequiddillas of Spain are
likewise national tunes; as are the elegant little street-
ongs of Venice, called Venetian ballads; and such are the
pleasing and popular Provencal and Languedoocian melodies,
very different from the Vaudeville and ballad tunes of the
Pont-neuf and frote of Paris.

Thus far concerns tune as a substantive: as a verb, to tune,
is a preparation for the performance of music. A sound
can be made sweet, clear, and very perfect in itself, yet agree
with none of its relatives on any instrument, or in any key:
it is then said to be out of tune. The regulator of all sounds
in a musical composition is the key-note of a diatonic scale,
in which every sound must be in tune with all the intervals.
"Tune your harps to cheerful strains;" that is, render
your harps fit for tune or song. This belongs to intona-
tion, found, musical tones. Intonazioni perfida, in Italian,
is an expression for false intonation, out of tune, in finging or
playing. So in French, intonation vraie, intonation fausse,
are musical expressions for true or false intonation. Enton-
teur, in Romish cathedrals, is to give the tone of an
anthem, a hymn, with the organ; and in our cathedrals, of
the refraomes.

Our great lexicographer, though no musician himself, has
defined the expression, to tune, with true technical accuracy,
in saying that it is "to put instruments into such a state, as
that the proper sounds may be produced." Dr. Holder
well defines the word tunable, when he says, "all tunable
sounds, of which the human voice is one, are made by a
regular vibration of the founorous body, and undulation of
the air, proportionable to the acuteness or gravity of the
tone."

Caeufe and Measure of Tone, or that on which a Tone of a
Sound depends.—Sonorous bodies, we find, differ in tone;
1. According to the different kinds of matter; thus the
found of a piece of gold is much graver, than that of a piece
of silver of the same shape and dimenlions; in which case,
the tones are proportional to the specific gravities.
2. According to the different quantities of the same
matter in bodies of the same figure; as a solid sphere
of brafs, one foot in diameter, founds acuter than a sphere of
brafs two feet in diameter; in which case the tones are pro-
portional to the quantities of matter. See GRAVITY.

Here then are different tones connected with different
specific gravities, and different quantities of matter: yet
cannot the different degrees of tone be referred to those
quantities, &c. as the immediate cause. In effect, the
measures of tone are only to be sought in the relations of
the motions that are the cause of sounds, which are no where
do discernible as in the vibrations of chords.

Sounds, we know, are produced in chords by their vibrat-
ory motions; not, indeed, by those sensibie vibrations of
the whole chord, but by the inappreciable ones, which are
influenced by the sensibie, and, in all probability, are propor-
tional to them. So that sounds may be as justly measured
in the latter, as they could be in the former, did they fall
under our fenses: but even the sensibie vibrations are too
small and quick to be immediately measured. The only
recourse we have, is to find what proportion they have with
some other thing: which is effected by the different tension
or thickness, or lengths of chords, which, in all other respects,
excepting some one of those mentioned, are the fame.

Now, in the general, we find that in two chords, all
things being equal, excepting the tenion, or the thickness,
or the length, the tones are different; there must, therefore,
be a difference in the vibrations owing to those different
tensions, &c. which difference could only be in the velocity
of the courses and recourses of the chords, through the
spaces in which they move to and again. Now, upon
examining the proportion between that velocity, and the
things just mentioned, on which it depends, it is found to
be a demonstration, that all the vibrations of the fame chords
are performed in equal times.

Hence, as the tone of a sound depends on the nature of
those vibrations, whose differences we can conceive no other-
wise than as having different velocities; and as the small
vibrations of the same chord are all performed in equal
time; and as it is found true in fact, that the sound of any
body arising from one individual stroke, though it grows
gradually weaker, yet continues in the same tone from first
to last; it follows that the tone is necessarily connected
with a certain quantity of time in making every single vibra-
tion; or that a certain number of vibrations, accomplished
in a given time, constitutes a certain and determinate tone;
for the frequenter those vibrations are, the more acute is
the tone; and the fower and fewer they are in the fame
space of time, by so much the more grave is the tone; so
that any given note of a tone is made by one certain measure
of velocity or vibration, i. e. such a certain number of
courses and recourses of a chord or string, in such a certain
space of time, constitutes a determinate tone. See SOUND.

This theory is strongly supported by our best and latest
writers on music, Dr. Holder, Mr. Malcolm, &c. both
from reason and experience. Dr. Wallis, who owns it very
reasonable, adds, that it is evident the degrees of acutenes
are reciprocally as the lengths of the chords; though, he says,
he will not positively affirm, that the degrees of acutenes
answer the number of vibrations, as their only true caufe:
but his diffidence arises hence, that he doubts whether the
thing has been sufficiently confirmed by experiment. In-
deed, whether the different number of vibrations in a given
time be the true caufe, on the part of the object, of our
perceiving a difference of tone, is a thing which we conceive
does not come within the reach of experiment; it is suffi-
cient the hypothesis is reasonable.

Tune by Water. To see LASUS, HYPPASUS, and
WATER.

TUNEKA, in Geography, a town of Ruffia, in the go-
vernment of Irkutfs, on the Ilim; 84 miles N. of Bal-
ganskoi.

TUNES,
TUNES, in Ancient Geography, a town of Africa, mostly on a hill, to the W., and on the border of the port named Stagnum by Procopius, situated S.E. of Carthage, and surrounded by lakes and marshes. See Tunis.

TUNG, in Natural History, the name given by the Indians to a little insect, called by the Spaniards pique, which is very common and very troublesome in some parts of the East and West Indies.

It is of the size of a small flea; its place of laying its eggs is within the skin of the human body, and it diligently searches opportunities of doing this, and often succeeds in the attempt, to the great pain and trouble of the person who suffers it.

The creature, knowing that it shall be soon crushed to death under the skin, generally makes its way either under the nails, or where there is some callus on the surface; there it eats its way along, and, in fine, lays its eggs, which hatch into so many young ones, and spread themselves between the flesh and skin all over the finger and hand, if not prevented by taking out the old one in time.

The person often does not perceive the creature's getting in, it enters so gradually and easily; but he is soon advertised of the place where it is by a violent gnawing pain, the creature really eating its way as it goes along. The only way then to get rid of this insect, is to enlarge the orifice at which it entered, and take it out whole; the wound soon heals up, and there is an end of the matter. This may often be done with the point of a needle; but if not, it is much better to submit to the opening it with a lancet than to all consequences which otherwise will attend it. Obferv. fur les Coutumes de l'Afie, p. 184.

TUNGA, in Geography, a town of Africa, in the kingdom of Tunis.

TUNGBADRA, a river of Hindostan, which runs into the Kistnah, 7 miles E. of Rachore, in the country of Golconda.

TUNGERSHEIM, a town of the duchy of Wurzburg, on the Main; 9 miles N. of Wurzburg.

TUNGINSKOI, a town of Rufia, on the Irrut; 80 miles S.W. of Irkutsk. N. lat. 51° 18'. E. long. 103° 14'.

TUNGONG, a town of Meckley; 16 miles S.E. of Munypour.

TUNGRI, or TONGRE, in Ancient Geography, the name of a people who, according to Tacitus, succeeded that of German, by which were designated the first people who from the other side of the Rhine had abandoned their territory to the Gauls. But according to other authors, the Tongres inhabited the country of Liege for a long time before the entrance of the Romans into the Gauls. Conquerors of the Eburons, they succeeded them, so that they were entirely forgotten. Their conquests were very extensive; and though they were subjugated by the Franks, and Attila, commanding the Huns, completed their extermination, yet their bishops long after retained their title.

TUNGSTEN, in Mineralogy; Scheelites calcarea, Haüy.
The name tungsten, denoting heavy stone, was given to this mineral on account of its great specific gravity. Its appearance is not metallic, it has a yellowish or greyish-white colour, and is more or less translucent. The structure is lamellar; it is insusceptible by the blowpipe, but becomes opaque. When powdered and digested with nitric acid, it communicates to it a yellow colour. These properties distinguish it from carbonate of lead, white tin-dolce, and barytes. Tungsten occurs both massive and crystallized; the form of the crystals is most frequently the octahedron. The primitive form of the crystal, according to Haüy, is an acute octahedron, having the angle at the summit 62° 24', and the angle formed by the junction of the planes at the base of each pyramid 113° 51'. The principal planes of the crystals are smooth, the lustrous splendent. Tungsten yields to the knife, and is brittle; its specific gravity varies from 5.800 to 6.015. This mineral occurs with wolfram, (see Wolfram.) tin-dolce, magnetic iron-dolce, and brown iron-dolce: it sometimes forms large or small granular distinct concretions with flecked and shining surfaces. It is found in the mines of Cornwall, Sweden, Bohemia, and Saxony. Its constituent parts are,

| Acid of tungsten | - | 75.25 |
| Lime | - | 38.70 |
| Silex | - | 1.56 |
| Oxid of iron | - | 6.25 |
| Oxid of manganese | - | 0.75 |

Tungsten, in Chemistry, is the metal obtained from the ore of the same name above described. By some of the German chemists it is denominated Sch melium, from Scheele, who first pointed out the peculiar nature of one of its oxides.

Tungsten was first obtained in the metallic state by the Meffrs. D'Elhuyart from another of its ores called cunifram. New experiments have been since repeated by Vaucquelin, Klaproth, Meffrs. Allen and Aikin, and others, with various success, and very lately they have been confirmed by Buchholz.

This metal has been obtained by expelling the tungstate of ammonia to a violent heat. It has never been procured in the state of a solid button, or in large panes, but only in small panes as fine as sand, having a strong metallic lustrous, a light iron-grey colour, and slightly agglutinated. It is one of the hardest of the metals, and very brittle. Its sp. gr. according to the D'Elhuyarts, is 17.6; according to Meffrs. Allen and Aikin, 17.2; and according to the late experiments of Bucholz, 17.4, which is about the mean of the others, and probably very near the truth. Hence, next to gold and platinum, it is one of the heaviest metals.

This metal requires a heat of at least 175° of Wedgwood (probably much higher) to melt it. It is not attracted by the magnet. Exposed to heat in an open vessel, it gradually absorbs oxygen, and is converted into an oxide. Two oxides of this metal were formerly known, viz. the dark blue or black, and the yellow or tungstic acid; but besides these, Bucholz has lately described another of a dark brownish-red or reddish-brown colour, and which he considers to be intermediate to the other two. Of these, the blest brown and most important is the yellow oxide, or tungstic acid. This oxide is without taste. It is insoluble in water, but remains long suspended in it. It has no active or vegetable colours. It is flated to be composited of

Tungsten | - | 80
Oxygen | - | 20

Little is known of the nature and composition of the other oxides of this metal, so that we cannot with any degree of certainty ascertain the weight of its atom. This metal combines with sulphur and phosphorus, and forms alloys with many of the metals; but these compounds do not appear to be interesting. The yellow oxide, or tungstic acid, seems capable of forming compounds with all the alkaline, earthly, and metallic bases, though very little is known at present of the nature of these compounds.

TUNGURAGUA, in Geography, a mountain of Peru; 21 miles S. of Riobamba.

Tunguragua. See Maranon.

TUN-
TUNGUSES, a branch or division of the Mandchures, or Mandhu, who originally composed one people with them, as appears not only from their mutual resemblance in features, manners, and customs, but chiefly from their agreement in language. The Tunguses call themselves "Evees", probably from the first ancestor of their race; or, like most of the Siberian tribes, from the word which in their language signifies "men". They are called Tunguses only by the Oltiaks of the Yenifley and the Tartars. By the Mandhus, they are denominatet Soloni, protectors, or Oranoffiun, people with reindeer. The extensive deferts in which they now inhabit, reach from W. to E. from the Yenifley across the Lena, as far as the Amoor and the Eastern ocean. From S. to N. they keep between about the 53rd and 65th degree of N. lat., and accordingly touch neither upon the Soungarian borders, nor upon the coasts of the Frozen ocean. Being of an accommodating disposition, they have admitted into their seats Oltiaks, Samoyedes, and particularly Yakutans. The districts now mentioned lie mostly in the government of Irkutsk; nevertheless, some few races of the Tunguses are reckoned as belonging to the government of Tobolik. The first accounts which the Russians obtained of these people were received from the Oltiaks of the Yenifley; and in the year 1667, Coffacks were first sent from Mangajei against the Tunguses, to force them into submission. On occasion of these Russian attacks, the Tunguses displayed a greater degree of courage than the other Siberians; nor were they brought to the imperfect state of submission in which they are now held, till the latter half of the last century. By the enumeration of the year 1766, they confided of 12,000 males; but besides these, different Tunguiian tribes wander among the Siberian nations, who together amount to about 1700 yoorts, or families. Although they constitute one of the most numerous nations of Siberia, yet, on account of their roaming mode of life, few items of them can be actually registered. The Tunguses who nomadize about the coasts of the Eastern ocean, are known under the name of "Lamuts". Of these, in the forementioned year, only about 400 men were enrolled to the payment of tribute.

The Tunguses are indefatigable in the chase, and are constantly changing their habitation. In the season of fishing and of collecting berries, they remain for some time nearly stationary; and then they remove their tents, leaving their supplies of dried fish and berries in large boxes, constructed on trees or poles, for the benefit of themselves and their tribes, in travelling during the winter. They feel callous to the effects of heat or cold; their tents are covered with shawmoy, or the inner bark of the birch, which they render as pliable as leather, by rolling it up, and keeping it for some time in the flame of boiling water and smoke. Their winter drefs is the skin of the deer, or wild sheep, dressed with the hair on it; a breast-piece of the same, which ties round the neck, and reaches down to the waist, widening towards the bottom, and neatly ornamented with embroidery and beads; pantaloons of the same materials, which also furnish them with short stockings, and boots of the legs of rein-deer, with the hair outward; a fur cap and gloves. Their summer dresses only differ in being simple leather without the hair. They are religious observers of their word, punctual and exact in traffic; some few are drilled; but most of them are Demonsolitarians, have their forcerers, and sacrifice chiefly to evil spirits. They commonly hunt with the bow and arrow, but some have rifle-barrelled guns. Instead of burying the dead, they place the body, dressed in its belt apparel, in a strong box, and suspend it between two trees. The implements of the chase belonging to the deceased are buried under the box. Except a forcerer is very near, no ceremony is observed; but in his presence they kill a deer, offer a part to the demons, and eat the rest. They allow polygamy, but the first wife is the chief, and is attended by the rest. The ceremony of marriage is a simple purchase from her father; and the price is from 20 to 100 deer, or the bridegroom works during a stated time for the benefit of the bride's father. The unmarried are not remarkable for chastity. A man will give his daughter for a time to any friend or traveller to whom he is attached; if he has no daughter, he will give his servant, but not his wives. They are in size somewhat below the common stature, very active, and have lively inviting countenances, with small eyes; and both sexes are very fond of brandy. The Tunguses wander about the mountains, and seldom visit such plains as are occupied by Yakuts; but frequently resort to the solitary habitations of the Coffacks, appointed to the different flanges; as they are there generally supplied with brandy, needles, thread, and such trifles as are requisite among them and their women, who always accompany them in their wanderings. See Mandchures.

TUNGUSKA, a river of Russia, which rives in lake Baikal, and runs into the Enifie, about 20 miles S. of Enifie; in the former part of its course it is called Angara, in the latter Tungulka or Yenifley.

This Upper Tungulka, for there are three rivers of the same name, which bears the name of Angara till it unites with the Ilim, takes up several other rivers, as the Koda, the Thalovetch, the Iriki, the Kamenka, the Olenka, and the Tatarkiaia, all on the right; and to the left, the Oka, and the Tihuna or Oda. This Tungulka has for the most part a bed strewn with rocks, and forms several cataracts, five of which are very considerable. Although it be navigable, the navigation is toilome and difficult. The Middle or Podkammenia Tungulka rives in the government of Irkutsk, among the Baikal mountains, not far from the origin of the Lena; and after a course of about 850 versts, and after having, on the right, taken up the Thina and the Thorna, falls into the Yenifley in 62° N. lat. The Lower or Niznej Tungulka takes its source in the same district, but bends its course northward, and after having taken up on the left the rivers Niepa, Svetlaia, with many others, and on the right the Rosmakka, the Turija, and the Gorela, and running a course of about 1500 versts, strikes into the Yenifley, not far from Turukanik. In this river are several dangerous whirlpools.

TUNGUSKOI, Ust, a town of Russia, in the government of Tobolik; 24 miles S. of Enifieik, at the confluence of the Enifie and Tungulka.

TUNGUSLI, a town of Russia, in the government of Tobolik, on the Obi; 56 miles S. of Tara.

TUNIA, or Tunja, a town of South America, in the vicerey of New Granada; 60 miles N. of Santa Fe de Bogota. Tunia, founded in 1539, was formerly an opulent town, but has now declined, the inhabitants not exceeding 400. The edifices retain marks of former splendour, and the parish-church might well serve for a cathedral. Here are three convents, that might answer the marks of manufacture. N. lat. 5° 5'. W. long. 72° 50'.

TUNIC, in Botany and Vegetable Physiognomy, the English name of the appendage to certain seeds, termed Arillus in Latin; see that article, where, however, the explanation given by our predecessor, Dr. Woodward, refers only to the use of the term Arillus in the genus Carex. The Tunic, or Arillus, is attached to the base only of the seed, immediately adjoining to the Scar, Hilum, and envelops the rest of the seed more or less completely and closely. Its size and texture, as well as colour, are various. In the Spindle-tree,
TUN

Tree, *Euonymus*, the part in question is a pulpy, wrinkled, orange-coloured wrapper; in *Afzelia* a beautiful, firm, close, scarlet cup, embracing great part of the lower half of the black hard seed; in *Hippophae* a double membranous, but tough, coat, within the pulp of the berry; in *Myrsitica*, the netting, a jagged, brittle, lathyrohedral, complex integument, well known by the name of Mace. *Narthexium*, and great part of the *Orchidaceae*, have each of their minute seeds clothed in a lax membranous Tunis, extending beyond them at each end, and probably designed to give them buoyancy, like a fort of wing. *Oxalis* has an elastic pouche-like Tunis, serving to project its polished seeds to a distance, like the hard rigid bivalve Tunis of *Dillamnum*, *Boronia*, and their allies. (See Rutaceae.) That curious genus named by M. Konig, in Ann. of Bot. v. 2. 560, *Bliza*, the *Ake* of Guinea and the West Indies, has each seed supported by a large, fleshy, lobed Tunis, for which alone, as a delicate article of food, the tree is cultivated. Some difficulty occasionally arises in distinguishing between a real *Arilus* and the *Tefla* of certain seeds, or at least the outer coat of the latter. (See Testa.) This difficulty occurs in the order of *Apertifidae*, *Myrtaceae* and *Gynophyllaceae*, while the real capsules of *Germium*, *Pelargonium*, *Malva*, &c. have, on the other hand, been sometimes called *Arilli*.

TUNICA, a kind of wailcoat, or under garment, worn by the ancients, both at Rome and in the East. The common people ordinarily wore only a tunica; but those of better fashion wore a toga or gown over it. The philosophers wore a gown without a tunica, as professing to go half naked.

The tunica was peculiar to the men; the under garment of the women not being called tunica, but *foba*.

The fenators wore their tunicas enriched with several little pieces of purple, cut in form of large nails; whence it was called *laticlavias*: the knights had less nails on their tunica, which was hence called *angustilavias*: the common people wore their tunicas without any *clavi* at all. And it was by these three different forts of tunicas, that the three different orders of the Roman people were distinguished in habit. It has been a common opinion, that the *angustilavias* distinguished the knights from the common people, in the same manner as the *laticlavias* did the fenators from those of the equestrian rank. But Rubenius averes that there was no manner of difference between the tunicas of the knights and those of the commons. As to the perfons who had the honour of wearing the *laticlavias*, it may be maintained, says Kennet (Ant. of Rome, p. 308.), that the fons of those fenators who were patricians had the privilege of using this velt in their childhood, together with the *prætexta*. But the fons of such fenators as were not patricians, did not put on the *laticlavias* till they applied themselves to the service of the commonwealth, and to bearing offices. Yet *Augurius* changed this custom, and gave the fons of any fenators leave to alluminate the *laticlavias* presently after the time of their putting on the *toga virilis*, though they were not yet capable of honours. And by the particular favour of the emperors, the same privilege was allowed to the more splendid families of the knights. In the declension of the empire, the tunicas did not only reach down to the angles, whence they were called *talares*, but had sleeves too coming down to the hands, whence they were called *thiodotes*. And now it was counted as scandalous to appear without sleeves, as it had been hitherto to be seen in them; and, therefore, in the writers of that age, we commonly find the accursed perfons at a trial habitated in a tunic without sleeves, as a mark of disgrace and infamy.

Vol. XXXVI.

Beside the different forts of tunicas above-mentioned, there was also the *tunica palmata*, worn by generals in a triumph, and perhaps always under the toga picta. It hath its name either from the great breadth of the clavi, equal to the palm of the hand, or else from the figures of palms embroidered on it.

Among religious, the woolen shirts, or under garments, are stiled *tunicas* or *tuniques*.

TUNICA, in Anatomy, a technical name applied to the membranes which compose various organs; thus the serous and mucous membranes, and the muscular fritum of the stomach or intestines, are called their tunicae: in the same way we have the tunicae or coats of the eye, the blood-veffels, the teftes, &c. &c.

TUNICA, in Botany, a name adopted by Dillenius, as he himself avows, from the apothecaries, and perhaps originally corrupted by them from *Vitónica*, or *Botónica*, its synonyms. Thefe names all belong to the *Flus Caryophyllyus*, *Clave-flowers*, *Carnation*, or *Pink*; and Dillenius was led to the above choice, for the purpofe of removing the ambiguity arising from *Caryophyllyus*, (fee that article,) as properly belonging to the valuable fpice called Claves. *Linnaeus*, not satisfied with either appellation, invented a new one, which has been generally approved. See DIANTHUS.

TUNICATED ROOTS, among Botanists, such as are formed of a multitude of coats surrounding one another. See Root.

TUNIQUK, in Geography, a town of Hungary, on the river Samos; 6 miles E. of Efced.

TUNIS, a city of Africa, and capital of the country so called, situated on a rising ground, on the west bank of a lake, or rather a shallow in form of a lake, communicating with the gulf by a narrow channel. The situation of Tunis, probably first chosen by some fishermen, to whom that of almost all the marine cities is to be ascribed, appeared to the inhabitants to be preferable to that of Carthage; as soon as, enriched by rapine, they dared openly to attack the trade of every nation. The eminence on which the ruins of Carthage, N.E. of Tunis, that ancient rival of Rome, advances into the middle of the gulf, and on that account would have exposed the Tunifians to be taken by surprife. This city was called, by Diodorus Siculus, "Léon Tunétas," that is, White Tunis; perhaps from the chalky cliffs which lie round it, when viewed from the sea; and was founded about 1250 or 1300 years B.C., as appears from Herodotus and the Parian chronicle. It is surrounded by lakes and marshes, which, however, do not render it unhealthy, which is, by Dr. Shaw, attributed to the number of mallich and myrtle trees, roemarfly, and other gummy and aromatic plants, with which they heat their ovens and their baths; the water is obtained a mile distant, for the general use of the inhabitants. The infected atmosphere of Tunis is attributed by baron de Tott to the putrid emanations of a channel, which conveys all the filth of the city to a neighbouring lake; which lake likewise produces exhalations that appear no less dangerous; and the falsibility of Tunis, he says, can only be attributed to the depth of the valley, which comes down to the gulf, and which, by attracting the vapours of the channel and the lake, does not allow them to acquire that degree of corruption which would render them hurtful to the constitution of the inhabitants. The Tunifians are the most civilized nation of Barbary, with little of the insolent haughtiness of the Algerines; and affairs with the government are transacted with ease: the English, French, Dutch, and several European states, having confuls here, who are treated with civility and respect. Including the suburbs, Tunis is, by Dr. Shaw, supposd to
TUNIS.

to be rather more than three miles in circumference, and
the number of houses 10,000 or 12,000, and of inhabitants
about 50,000. But Bruns, on the authority of Sprengel,
reckons the houses at 12,000, and the inhabitants, by an
exaggerated statement, at 200,000 or 200,000, of whom
more than one-half perished by the plague of 1789. There
are few buildings of any magnificence, except the great
mosque, the bey's palace, called Barta, at some distance
from the city, encompassed with walls and flanked with
towers, and a few others: there are five gates, but none of
them grand. Near the centre of the city is a piazza of vast
extent, which is filled formerly to have contained 3000 ships
for the sale of woollen and linen goods; in the manufacture
of both which this city has been long famous. Here are
several colleges and schools, with many learned men and
deleuters. The Mahometans, though thinly mantained by the
public; the janizaries are quartered in barracks: other
public buildings are, an exchange, a custom-house, and an
arsenal. On the side of a canal is the fortress of Goletta,
but not carefully supported. The chief defence is the
castle. In 1655, Tunis was bombarded by the English
under admiral Blake. N. lat. 36° 44'. E. long. 10° 20'.

Tunis, the central region of Northern Africa, usually digni-
ified with the title of kingdom; bounded on the north and
cast by the Mediterranean, on the south by Tripoli, and on
the west by Algiers. This is the western part of the proper
Africa of antiquity, and was formerly the chief seat of Car-
thagian power; and in the middle ages, Tripoli was sub-ject to Tunis, which was feized by Barbarossa in 1533.
It is now about 200 miles from north to south, and 120
from east to west. According to Disfontaines, this king-
dom begins in the east at the island of Garib, and terminates
in the west at the river Zaine, called also Tufca or Sufca.
After the decline of the Roman empire, this country came
under the power of the Vandals and Goths; and after the
decline of the Vandals and Goths; and after the
invasion of the Moors, was successively governed by the
viceroyes, called emirs. It afterwards became subject to the
emperor of Morocco. For a space of time it was an in-
dependent and powerful kingdom. In the year 1538, it
was overrun by Barbarossa; and notwithstanding the ene-
devours of Charles V. and his succes5ors, the kingdom was
made a province of the Ottoman empire, under the dominion
of Selim II., by Sinan, bashaw of the Levant. At present
the whole kingdom is divided into two circuits, the summer
and the winter, which the bey makes in perfon through his
dominions at those two seacons. The summer circuit, or
northern district, is by far the most pleasant, fertile, and
populous, and has the greatest number of cities, villages,
and downs, and carries the fairest appearance of plenty,
prosperity, and cheerfulness of the two; advantages owing
to the mildness of its government, and its being freer from
tyranny and oppression than that of Algiers. The Tu-
nisians, in general, are like the Algerines; a mixture of
Turks, Moors, Kabits or indigenous inhabitants of the
mountains, Arabsians, Jews, and Christhians, merchants, and
flaves; with this difference, that they are here polite and
civilized. They are much more kind and humane to their
flaves, in general; though they treat the knights of Malta
with greater severity. In other respects, the Tunisians are
courteous to strangers; and all affairs with the regency are
transacted in a very friendly manner: the confuls that reside
here are treated with greater affability and condescension,
juricrce, and dispatch, than in any other court on the African
coasts: in a word, this nation hath, for many years, been
more intent upon trade, and the improvement of their manu-
factures, than upon plundering and cruizing; upon which
account, it hath cultivated the alliance of many Christlian
powers. The drefs of the Tunisians, of both sexes, is much of
the same fashon with that of the Algerines. The women
are handsome, neat, and more familiar: they go, indeed,
veiled out of doors, but are allowed to be seen and converse
with strangers, their husbands not being tainted with such
jealousy as reigns among other Aftricans. The religion is
the fame as that of the Algerines. This kingdom, as well
as Algiers, and others along the Barbary coast, are very
subject to earthquakes, which commonly happen after heavy
rains, at the end of the summer, or in autumn, and are
often felt at a great distance from land, where the depth of
water hath been above 200 fathoms: in other refpects, the
country is, for the most part, as healthy and fertile as any
under the same climate. The northern parts, which are the
bell cultivated, enjoy a wholesome temperature. The
winds are mostly from the sea, confequently refreshing;
but those that blow from the southern fandy desertcs are quite
fuffocating, especially as they prevail mostly in July and Aug11: if they continue
five or fix days successively, the inhabitants are obliged to
keep themselves cool by sprinkling their floors with water.
The sea-winds, that blow well-north-west and north, bring
dry weather in summer, and rain in winter; but the easterly,
as well as the southerly, are for the most part dry, though
louring with a fandy, cloudy atmophile in moft feasons.
Their first rains commonly fall in September, and sometimes
in October; about three weeks after which, the Arabsians
break the ground, low their corn, and plant their beans,
bayery, lentils, and garvancos; their harvest usually begins
in May, or the beginning of June, according to the quality
of the preceding feaon. The Tunisians are much more ad-
dicted to agriculture than their neighbours, the Algerines,
and are for making the moft of every inch of their ground.
 Mines of metal and minerals they disregarde; though Dr.
Shaw oberved, among the mineral productions of Tunis,
alabaster, cryf tal, bollc, plumbago, iron, and lead. The
caffle are small and slender, and the horses have degenerated.
Here are lions, panthers, hyenas, chakals, and other fer-
orous animals. The manufactures are velvets, silks, linen,
and red caps worn by the common people. The govern-
ment of Tunis at prrefent, like that of Algiers, is altogether
depopat; but with this difference, that there it is elective,
and here not only hereditary, but the bey hath power to
name which of his fons he pleafes for his fuccesfor, with-
out regard to eldphanship; or, in cafe he doth not think
worthy, he may appoint a brother, or a nephew, to the
fuccesfor; in all other cafes, likewise, they are equally ab-
olute and independent, either on the Pore, or the Douwan
or Divan. They were once, indeed, under the protection
of the former; and the rapacious extortion and tyranny of
its bashaws had, in some measure, obftrided them to fchake
off their yoke, and form a government of their own, which
they fettled in fuch a manner, that their deys, as they were
then called, could do nothing without the advice and con-
fent of the Douwan or Divan; but they have found means,
in time, to rid themfelves of this uncaufy clog also, though
they
they still retain a kind of form or shadow of both. The Porte hath a baffal reeding here, but in power and influence he is a mere cypher, and serves only to remind the Tunisians, that they were once subject to the Turkish sultans. The Douwan, being chiefly composed of friends and creatures of the Bey, is rather assembled to give a forced approbation to their resolutions, than to consult them about the justice or expediency of them. At the first settling of this new form of government, the deyhip was the supreme dignity, as it is still at Algiers; as that of bey was the next in rank, but wholly subordinate to it. However, having since built their power upon the ruins of the deys, they have, by degrees, raised the beyhip to be despotic and independent; and by making it hereditary, have prevented, in a great measure, those frequent depredations, rebellions, and mafacres, which are the almost constant concomitants of the regal authority, wherever it is made elective. Yet far from preventing jealousies, cabals, and rebellions, in spite of all their precautions, the dignity oftener falls to the share of that fon who has been able, by his address, to form the strongest party, than to him who hath been appointed to it by the father. Hence it is, that whenever the throne becomes vacant, whether in the course of nature, or by open treason and rebellion, it is seldom filled up again without a great deal of bloodshed, rapine, and violence, in proportion to the number of competitors. In the summer the bey of Tunis refides in the northern part, and in the winter retires to the south, where is a lake of considerable extent, the "Palus Tritonis" of antiquity. The authority of the bey extends over a large tract of country, of which he receives the tribute, with a small army, which marches out annually for that purpose. Tunis, which had formerly a considerable commerce with France, exports thither corn, oil, beans, lentils, wax, wool, hides, and Morocco skins; and receives, in exchange, Spanish wool, Languedoc cloth, vermilion, sugar, pepper, cloves, wine, brandy, paper, hardware, iron, and steel. The Italian trade is wholly carried on by the Jews, who fend the fame commodities to France, and import from thence Spanish cloth, damasks, several sorts of silk and woollen stuffs, gold and silver tiifue. The French pay 3 per cent. for all the goods they bring from France, and the Jews 10 per cent. on their imports from Italy. The Turks and Moors export to the Levant woollen stuffs, lead, gold-duft, and chequins, and a vast number of bales of caps; and bring, in return, silks, calicoes, iron, alum, and vermilion. They fend much the fame kind of commodities into Egypt; but the oil that is carried thither must be put up in jars, and not in calts, because the greatest part of it is designed for the lamps of Mecca and Medina; and the Arabian would think it polluted, as the vessels might formerly have contained wine. They import, in exchange, from thence, linen, cotton, rice, flax, and coffee. The number of French ships freighted at Tunis, by Turks, Moors, and Jews, has amounted yearly to one hundred and fifty to the Levant, and fifty for France and Italy; as for those of the English, their number is uncertain. All public conventions and instrumens are written in the Arabic tongue, but the public commerce is commonly carried on by the medium of the Lingua Franca. Gadames, or Galamis (which see), had formerly a flourishing commerce; but it has ceased since the caravans palling from Tripoli to Tombuctoo do not flop there, but at Agadez. The caravans of Tombuctoo bring slaves, ostrich feathers, ivory, and amber; those of Sallee, gold, as well as thosfe of Gadames, which also bring Negro slaves. Ruins of ancient monuments are found near Zowas, Spitola, Chaffa, Thridifta, Hammamcel, and Chispa. Desfontaines mentions in particular with admiration a large and beautiful amphitheatre near Elgum. Some vestiges are also found here and there of an ancient Carthagian aqueduct, which served to draw water from the springs of mont Zouan; but there scarcely exist any other remains of Carthage. Near the river Mejerdja are still seen some ruins of Utica, which are, at present, at the distance of about 4000 fathoms from the shore; though this city was formerly a sea-port.

At Tunis, accounts are kept in piastres of 52 aspers, each asper being divided into 12 burbes. The coins consist of gold tunstans, valued at 100 aspers; of silver naturas (a square or shapeless coin), valued at 52 aspers; and of doubts, valued at 24 aspers. The burbes are a small copper coin. Gold, silver, and pearls, are weighed by the ounce of 8 termini; and 80 ounces of Tunis = 81 ounces English troy. The cantaro, which is a weight for merchandise, contains 100 rottoli, weighing about 111 pounds avoirdupois. The castillo, a corn measure, contains 18 wents, or 216 liras; 53 castii = 67/4 English quarters. The mattaro, an oil measure, is = 32 rottoli, = 351 pounds avoirdupois, and is about 5 English gallons. The mattaro, wine measure, is only half that for oil measure. The pic, long measure, is for woollen 208.3 French lines, or 264 English inches, for silk 24½ English inches, and for linen 18¾ English inches.

TUNKAT. See Toncat.

TUNKERSTOWN. See Ephata.

TUNKHANOCK, a township of Pennsylvania, in the county of Luzerne, containing 884 inhabitants.

Tunkhanock Creek, a river of Pennsylvania, which runs into the eafth branch of the Susquehanna, N. lat. 41° 31'. W. long. 75° 37'.

TUNNA, in Commerce, a measure of grain in Sweden, equal to four buhels five quarters Winchester measure.

TUNNAGE, or Tonnage, a duty or custom due for merchandise brought or carried in tons, and such like vessels, from or to other nations; thus called, because rated at so much per ton.

Tonnage is properly a duty imposed on liquids according to their measures; as poundage is that imposed on other commodities according to their weight. See Poundage and Customs.

Tonnage is also used for a certain rate paid the mariners, by the merchants, for unloading their ships arrived in any haven, after the rate of so much per ton.

TUNNEL, or Tunnei, an instrument through which any liquor is poured into a ve defe.

Part of a draught of a chimney, above the mantle-piece, is also called by the same name.

Tunnel is a large subterraneous arch, driven through a summit or hill, for the passage of boats upon a canal continued through the same; also, smaller drains or culverts are called tunnels; and the execution of making and driving them is called tunnelling.

Tunnel-Pit, a well or shaft sunk to the line of an intended tunnel, through which the fluff extracted from it is drawn up to the surface.

Tunnel-Kiln, in Agriculture, a term applied to a lime-kiln in which coal is burned, in contradistinction to that in which wood, peat, and other such matters are used, termed the flame-kiln. See Lime-Kiln.

There is much left waste of heat in the former forts than in those of the latter, and they have much advantage in the quick dispatch in drawing the lime; as, in the flame-kilns, after the matters are burnt, much time is lost by waiting until the lime be cold, and by emptying it at the mouth.
The most regular method is, to cleanse and tun full as it comes to a due ferment, and gets a good head; for then it has the mellow strength to clear itself. What works out of the cask is to be supplied with fresh beer of the fame brewing.

Tunning-Diff, a term applied to a large wooden dish, employed with a funnel, in tunning malt liquor.

TUNNUNDTORBIK, in Geography, an island near the coast of East Greenland. N. lat. 66° 45'. W. long. 46° 50'.

TUNNY, in Ichthyology, a name given by us to the Spanish mackerel, a large fish of the scomber kind, called by authors thymus and argynnus, by Salvian limofa, and pelamys by Ariritole, Aelian, and the other old writers. See Scomber.

In the lochs on the western coasts of Scotland, as well as in the Mediterranean (see Scomber Thymus), tunnies are also found in pursuit of herrings, and fold to people, or others carry them fresh to the country markets, or salt and preserve them in large casks. The pieces, when fresh, look like raw beef, but when boiled turn pale, and have somewhat the flavour of salmon. One of them has been found to weigh four hundred and fifty pounds.

TUNS, Thes, in Geography, rocks in St. George's Channel, near the coast of Ireland, and county of Wexford; 3 miles N.E. from the Saltex islands.

TUNSLA, a town of Sweden, in the province of Savolax; 52 miles N. of Nyflor.

TUNSTALL, JAMES, D.D., in Biography, a learned divine, was born about the year 1710, and educated at St. John's college, Cambridge, of which he was a tutor and fellow. In 1741 he was chosen public orator of the university, and became one of the chaplains to archbishop Potter. It was said of him, that many came to Lambeth humble, but no one left it but Dr. Tunfall. He was created D.D. in 1744, and in 1757 took possession, upon an exchange, of the valuable vicarage of Rochdale, in Lancashire; but his life terminated in 1772. He had a controversy with Middleton concerning the letters between Cicero and Brutus, of which he had made great use in his "Life of Cicero," and which Tunfall not only refuted, but proved, in the judgment of Markland, to be suppositional. He was also the author of some other publications: the principal of which is his "Academia, Part I., containing several Discourses on the Certainty, Distinction, and Connection of Natural and Revealed Religion," continued, as it is suppos'd, by Part II. printed after his death, under the title of "Lectures on Natural and Revealed Religion, read in the Chapel of St. John's College, Cambridge." Nichol's Anecdotes.

TUNSTEDE, or TUSTENDE, an English D.D., and a learned musician, who flourished in the fourteenth century. Pits, Bale, Tanner, and all our biographical writers, speak of him with respect. And among the MSS. at Oxford, we found, in 1780, a Tract on Music, entitled "Quatuor Principalia Artis Musicæ," by this writer, dated 1551, Bodl. 515. bound up with other tracts.

What this author calls the four principia of musica, will beat appear from his own manner of dividing the work. In the first part or principal, consisting of nineteen chapters, he treats of music in general, its constituent parts and divisions. Secondly, of its invention, intervals, and proportions; twenty-four chapters. Thirdly, of plain chant and the ecclesiastical modes; fifty-eight chapters. Fourthly, of measured music or time, of difant, and their several divisions. This last principal is divided into two sections, of which the first contains forty-one chapters, and the second forty-
TARAZ. Hence perennial, but the town of Tepic, on the west branch of the Nile; 6 miles N.N.W. of Amuris.

TUNUPOLON, in Zoology, the name of an East Indian species of viper, found principally in the island of Ceylon; it is of a small size, and of a fine, skin-like gloss, beautifully variegated with shades of brown. Ray.

TUONI ECCLESIASTICI, Ital., in Myces, tones of the church. (See CANTO FERMO and MONI.) The modi autenticu are the odd numbers 1, 3, 5, 7; and the modi plagal, the even numbers 2, 4, 6, 8.

TUONO, Ital., a musical tone or found. (See TONE.) “Tuoni,” says the Crufca, “appello a’ mufici, torno i gradi, per cui paflano fucceffivamente le voci e i fuoni nel falire verfo l’alimento, e nello fcendere verfo il grave colla regolata interpoftione de’ femettoni e loro lugghi per riempire gli intervalli maggiori confonanti, e diffonanti.”—“Tones among fufonic are those degrees or graduations by which voices and instruments ascend and descend fucceffively from the grave to the acute, and defcend from the acute to the grave, with the interpoftione of the neccafary femettoni to fill the greater confonant and diffonant intervals.” Varchi.

In this arrangement of the scale, all the fimple and perfect confonances are found, that is, the key-note, the fourth, the fifth, and the diapason or octave.

TUP, in Rural Economy, a term often applied to a ram in different districts.

TUPELO TREE, in Botany. See NIss.

TUPERSDORF, in Geography, a town of Saxony, in the Vogtland; 4 miles N.E. of Oelcnitz.

TUPES, a town of Bohemia, in the circle of Chrudim; 8 miles N.W. of Chrudim.

TUPICA, a town of Peru; 30 miles S.E. of Lipes.

TUPINAMBAS, a nation of South American Indians, who inhabited near Rio Janeiro, but after the settlement of the Portuguese, removed towards the river of the Amazonas, where the Tapayos are now their descendants.

TUPISTRA, in Botany, an unexplained name, used by Mr. Ker, in Curt. Mag. t. 1655.—The plant which bears it, T. spumalida, was imported by Meflis Loddiges from Ambonya, in whose flower it flowered, for the first time, in April 1814. The learned author did not examine the fpecimen in a perfect flate, so that his ideas, like our, muft be chiefly derived from Mr. Edwards’s figure, the accuracy of which there is no rea fon to doubt, and from which the close affinity of this plant to Orontium japonicum is apparent. No botaniff however is as yet sufficiently acquainted with the parts of fructification in either to determine their generic character, or to distinguish them generally from O. aquatium. See ORONTIUM.

T. spumalida has a perennial tuberous root, with thick fibres. Stem none. Leaves few, eréct, equitant, lanceolate-oblong, entire, coriaceous, smooth, about two feet long. Stalk solitary, eréct, not a fpan high, fimple, cylinfrical, smooth, firm, purplish, bearing a dense fpake of numerous fcentless flowers, of a pale digny, or brownifl head-colour, quite feflile, with a bractea at the bafe of each. Calyx none. Corolla of one petal, bell-shaped; the limb in fix or more fpeaking segments, each bearing on its disk a fefellite, two-feflile, but feemingly imperfect, anther. A cylindrical body, four-feflile at the top, in the centre, looks like a fern and flagma.

TUPPER, in Rural Economy, a term frequently applied to a breeder and dealer in tups, in some districts, as those of the midland parts of the kingdom. See RAM.

TUPPA, a name given in Thibet to children, who at the age of eight or nine years are admitted into the mona-stery at Tshang-Loomboo, and who are occupied in receiving the inftruction suited to their age, and the duties for which they are defigned. See TSHINBA.

TUPPING, in Rural Economy, a term applied to the impregnating of ewes by the tups or rams.

TUPPING-TIME, the period or season of putting tups or rams to the ewes. It should be done neither too early nor too late, as in the former case the lambs are dropped too much in the cold weather, while in the latter they are liable to be of inferior size for the markets. It is confec-\.uently best done according to the nature of the situation and circumstances. See SHEEP.

TUQUILLIGASTA, in Geography, a town of South America, in the province of Tucuman, on the Salado; 4 miles S. of St. Yago del Eferro.

TUR KABAIN, a town of Artificial Turkey, in the government of Muful; 20 miles E. of Nifhibin.

TURA, a river of Ruflia, which rifes about 40 miles W. of Werchotura, in the province of Ekafrinburg, and runs into the Tobol, opposite Turfanpo, in the government of Tolbofik. See TOBOL. —Alfo, an island in the Grecian Archipelago. N. lat. 35° 34'. E. long. 24° 15'.—Alfo, a town of Hungary; 24 miles W. of Topoltzlan.

—Alfo, a town of the county of Tyrol; 24 miles S.W. of Trent.

TURA Bamba, a fpacious plain, in which flands the city of Quito.

TURALINZES, one of the fhir colonies which con-\rained for themselves permanent habitations, when the Tartars subjugated Siberia in the 14th cen:ury; hence their name (from Tura, fignifying in the Tartar language a town), which fignifies the fame with fettes. Ever since their arrival, they have inhabited the region on both fides of the river, which from them is denominated the Tura, between the Tava and the Her, in the Ekaterinburg and Topolbofik districts of the governments of Perme and Topolbofik. Their oldest fixed seat was the city of Tchinghiden; but when Yermak made the conquest of these parts, the khan Yepansi refided higher up the Tura in a city, which after their reftoration by the Ruflians was named Turenso, and bears this name at preient, though it is alfo called by the Tartars Yepantchena.

TURAMIANA, in Ancient Geography, a town of Spain, in the eallern part of Bética, S.W. of Urfi. According to the Itinerary of Antonine, it was on the route from Cathulo to Malacca, between Urfi and Murgi.

TURAN, in Geography. See TARAZ.

TURANCOURCHY, a town of Hindooftan, in Madura; 12 miles N. of Nattam.

TURANO, a town of Hindooftan, in Malwa; 18 miles N.E. of Oungin.

TURANO, a town of Naples, in Calabria Citra; 5 miles W. of Bifguanoo.

TURAPHILUM, SIMI-ELLILAI, in Ancient Geography, a town of Africa, in Mauritania Cafrarenis, situated in the mountains of the interior, S. of Caeimoun.

TURATTE, in Geography, a town of the island of Celeshe, and capital of a powerful kingdom: 180 miles N. of Macallar.

TURBA, in Ancient Geography, a town of Novempo- phulani, belonging to the Aquitanis, in Gaul.

TURBAH, TURBAH, the head-drefs of most of the Eastern
Eastern and Mahometan nations; confiding of two parts, viz. a cap, and a fath of fine linen or taffety, artfully wound in divers plaits about the cap. The word is formed from the Arabic دار, دار, or دار, دار, which signifies encomplia, and دار, دار, band or band, which signifies fathes, or ʃoar, or band; so that durant, or turban, or turbant, only signifies a ʃoar, or fathes, tied round; it being the fathes that gives the denomination to the whole turban. The cap is red or green, without any brim, pretty flat, though roundish at top, and quilted with cotton, but does not cover the ears. About this is wrapped a round piece of fine thin lincon or cotton, in several wreaths variously disposed.

There is a good deal of art in giving turbans the fine air; and the making of them up constitutes a particular trade, as the making of hats does among us.

The emirs, who pretend to be defended of the race of Mahomet, wear their turbans green: those of the other Turks are ordinarily red, with a white fathes. The gentled people have frequent changes of turbans. M. de Tournefort observes, that the turban, all things considered, is a very commodious dres; and that he even found it more easy to him than his French habit.

The grand signor’s turban is as big as a buffel, and is so exceedingly refreshed by the Turks, that they dare not touch it. It is adorned with three plumes of feathers enriched with diamonds and precious stones; he has a mi-nifter on purpose to look to it, called turbanogla. See Coronet.

That of the grand vizir has two plumes; so have those of divers other officers, only smaller one than another; others have only one, and others none at all. The turban of the officers of the divan is of a peculiar form, and called muzenrez.

The fathes of the Turks’ turban, we have observed, is white linen; that of the Persians is red woollen. These are the distinguishing marks of their different religions; Sophi, king of Persia, who was of the sect of Ali, being the first who appliued that colour, to disinguish himselt from the Turks, who are of the sect of Omar, and whom the Persians esteem heretics.

Turban, or Clavicle, in Conchology, denotes the aggre-gate, or whole set of the whirs of a shell, and forms its lower part. The flat, or helix turban, is one so slightly prominent, as to be nearly on a level. There are also the short turban, the produced turban, and the long turban.

Turban-Top, in Botany. See HELVELLA.

Turban-Shell, Cideris, in Natural History, the name of a genus of the echinodermata, which are of a hemispheric or sphenoidal figure, and have their name from the Latin Cideris, a Persian turban, as in some degree resembling that head-dres.

Of this there are several genera, and subordinate species. This class of the echinodermata is made out by the affinity of the foils, as well as the recent animals; many of the kinds being now unknown on any shores. Klein’s Echinod. p. 17. See ECHINODERMA.

TURBA, in Ancient Geography, a fountain of Palefline, at the foot of mount Giblon, according to William of Tyre.

TURBARY, Turbaria, a right to dig turf in another man’s ground; from turba, an old Latin word for a turf.

TURBARY, Common of, is a liberty which some tenants have by prescription to dig on the lord’s willing. See common.
Turbishing the whole economy; and has accordingly been used in the droppy, palsy, and apoplexy.

It yields a deal of refined matter in a spirituous menstruum, which Quincy observes does not affect the larger passageways much; but is very active in the smaller vessels, and glandulous contortions, which it wonderfully clears of all viscid adhesions.

Some apothecaries, either through ignorance or para

...fulphasjlavus. paflages used or now to losses for...great against doses, all Paracelsus, strong though. Some have...must be sufficiently washed and been saturated with mercury.

We may observe that turbth mineral becomes yellow only by being deprived of the adhering vitriolic acid, and that it remains white till it has been washed with a large quantity of water; and, in general, the more perfectly it is deprived of this, the better yellow colour it acquires. Some chemists have supposed, that a portion of vitriolic acid remains united with the turbth, though not enough to render it soluble in water; M. Beaumé affirms, that when sufficiently washed it contains no acid; but the latter experiments of M. Bayen prove the contrary.

This powder is called mineral turbth, from the resemblance it bears to the vegetable turbth of the Arabians, in strongly purging the most internal recesses of the body; for though it be insipid upon the tongue, yet it is possessed of very considerable virtues. Being boiled with water, it loses more of its salts, and thereby grows milder, and more safe; so it does also by being deglazed twice or thrice, or distilled with spirit of wine.

The powder, prepared in the manner above described, proves, though not corrosive, strongly emetic; operating, in this intention, the most effectually of all the mercurials that can be given with safety. It is used chiefly in virulent gonorrhea, and other venereal diseases accompanied with a great flux of humours to the parts: it is said likewise to have been employed with success in obstetrical constitutions, against leprous disorders, and obdurate glandular obstructions. The dose, as an emetic, is from two grains to fix or eight; though some constitutions, habituated to mercurials, can bear larger quantities. It may be given in smaller doses, as half a grain or a grain, as an alternative, after the same manner as the red calx of mercury; and even when utented as an evacuant, it may perhaps, as Malouin observes, be most adviseable to give only a small quantity at a time, as one grain, and repeat the dose every hour till the vomiting succeeds. Lewis's Mat. Med. and Diet. Chem. Art. Turbth mineral.

Turbth mineral appears to have been the grand secret of Paracelsus, which, in his scare German book of hospital medicines, he praises to extravagantly for the venereal and all chronic diseases. Sydenham also commends it in venereal cafes, given in the quantity of fix or eight grains, in strong habits of body, so as to prove emetic; but when imprudently used, it is apt to bring on a dysentery. Turbth mineral has been used as a ferrunatory, and is said to have made wonderful cures in both the eyes. Mr. Boyle relates a cure of this sort, performed by the famous empiric Adrian Glais-maker on Mr. Vatteville, a Swiss officer of distinction in the French service, and totally blind. This gentleman was ordered to snuff about a grain of turbth up each nostril, which immediately operated in a violent manner, by vomit, foool, sweat, salivation, and the lacrymal glands, for twelve hours together; and also cutted his head to swell greatly; but within three or four days after this single dose had done working, he recovered his sight. Boyle's Works, Abr. vol. i. p. 103.

We read of this preparation being given to the quantity of ten grains, with the same quantity of camphor, and fifteen grains of the pilul. ex dunc. to remove the swelling of the testicles. This medicine, which in the beginning vomited and purged, at last operated chiefly as an alternative. It is said to be successful in obdurate venereal and ferocious disorders. See Medic. Eff. Edinb. vol. iv. art. 4.

Turbth mineral is an excessive bright true yellow, of a great body like vermilion; will flow equally well, and work with oil or water much in the same manner. These qualities (says the author of the Handmaid to the Arts, vol. i. p. 107) render it very valuable for many purposes; as it is much brighter than any other yellow used in oil, except king's yellow, and is free from its nauseous smell, and cooler. Mixed with Prussian blue it yields a much finer green than from the king's yellow without ultramarine. As it is, however, procured, it requires levigation in water before it be used.

TURBO, in the Linnaean System of Zoology, is a genus of the Teefacea order of worms. Its characters are; that its animal is a flug; the shell univalve, spiral, and solid; and the aperture straightened, orbiculated, and entire. Gemelin, in his edition of Linnaeus enumerates one hundred and seventeen species, besides several varieties. See Turbo under the article Conchology.

In Da Cotta's System, the turbo is a genus of snails, with a lengthened clavicle or turban; which have generally a perfect round mouth; the columnella, or inner lip, not much faced outwards, and the body spire very bellied, so that the turban is suddenly, and not insensibly, produced from it. See SHELLS.

The most remarkable species of the turbo, or screw-shell, is that called failure by Rumphius, from its spires running up hollow, or with a space between them. This is a very scarce and valuable shell when large, but is often found small in the Adriatic.

Aldrovand, and many others of the old authors, make no difference between the turbanes and screw-shells, though the distinction of the genera is very obvious; the screw-shells having a long, large, and dentated mouth, which terminates towards the base in a narrower aperture than elsewhere; and the shell itself always runs to a very sharp point at the end; whereas the turbanes terminate in a less sharp point, and have thicker bodies, and always much wider mouths. The screw-shells are indeed very easily confounded with the buccina; and it requires more accuracy to disinguish them, than has fallen to the share of the generality of writers on these subjects an age or two ago. Aldrovand and Rondeletus have confounded these genera, and have brought in a third among them, by the epithet murettum, which, when applied to the buccina, is generally offered to bring into that family a shell of the murets clafs, and which might have been very properly called by that shorter name.

For the sake of distinguishing these, it may be observed, that the screw-shell is of a very long and slender shape, terminating in a very sharp point, with its spires running on imperceptibly, without any great cavity, and the base small and flat, as well as the mouth.
**TURBO** Cochlea, in Natural History, a name by which some authors have called the Persian shell, a species of conchologia globosa, or dolium.

Many have been puzzled with this shell, not knowing in what class to rank it; and Aldrovan has placed it at the end of his work, saying, that it would seem to belong to the turbinated kinds, but that it wants the turbo.

**TURBOT** in Ichthyology, a name given to the fish which, in the systems of Artemi and Linnaeus, is a species of pleuronectes, being the pleuronectes of the former, with the eyes on the left side, and a rough body, and the pleuronectes maximus of the latter, and the *rhombus maximus* after non squamosus of Ray. See Pleuronectes Maximus.

Turbots grow to a large size, some of them weighing from twenty-three to thirty pounds. They are taken chiefly off the north coast of England, and others off the Dutch coast. The large turbots (as well as several other kinds of flat fish) are taken by the hook and line, for they lie in deep water; the method of taking them in weirs, or flaked nets, being very precarious. When the fishermen go out to fish, each person is provided with three lines, which are coiled on a large oblong piece of wicker-work; the hooks being baited, and placed regularly in the centre of the coil. Each line is furnished with fourteen score of hooks, at the distance of six feet two inches from each other. The hooks are fastened to the lines upon needles of twisted horse-hair, twenty-seven inches in length. When fishing, there are always three men in each cable, and consequently nine of these lines are fastened together, and used as one line, extending in length near three miles, and furnished with 2520 hooks. An anchor and a buoy are fixed at the first end of the line, and one more of each at the end of each man's lines; in all four anchors, which are common perforated stones, and four buoys made of leather or cork. This line is laid across the current. The tides of flood and ebb continue an equal time upon our coast, and, when undisturbed by winds, run each way about six hours; they are so rapid that the fishermen can only shoot and haul their lines at the turn of tide, and therefore the lines always remain upon the ground about six hours; during which time the *myxine glutinosa* of Linnaeus will frequently penetrate the fish that are on the hooks, and entirely devour them, leaving only the skin and bones. The same rapidity of tides prevents their using hand-lines; and therefore two of the people commonly wrap themselves in the fail, and sleep while the other keeps a stiff look-out, for fear of being run down by ships, and to observe the weather. For storms often rise so suddenly, that it is with extreme difficulty they can sometimes escape to the shore, leaving their lines behind. Besides the cable, the fishermen have also a five-men boat, which is forty feet long, and fifteen broad, and of twenty-five tons burthen; it is so called, though navigated by fix men and a boy, because one of the men is commonly hired to cook, &c. and does not share in the profits with the other five.

This boat is decked at each end, but open in the middle, and has two large lug-fails.

All our able fishermen go in these boats to the herring-fishery at Yarmouth, in the latter end of September, and return about the middle of November. The boats are then laid up till the beginning of Lent, at which time they go off in them to the edge of the Dogger, and other places, to fish for turbot, cod, ling, flates, &c. They always take two doubles on board, and when they come upon the ground, anchor the boat, throw out the doubles, and fish in the same manner as those who go from the shore in a coble; with this difference only, that here each man is provided with double the quantity of lines, and instead of waiting the return of the tide in the coble, return to their boat and bait their other lines; thus hawling one set, and shooting another every turn of tide. They commonly run into harbour twice a week to deliver their fish.

The best bait for all kinds of fish is fresh herring cut in pieces of a proper size; the five-men boats are always furnished with nets for taking them. Next to herrings are the leffer lamprey. The next baits in esteem are small haddock cut in pieces, sand-worms, and limpets, here called *finders*, and when none of these can be had, they use bullock's liver. The hooks are two inches and a half long in the shank, and near an inch wide between the shank and the point. The line is made of small cordage, and is always tanned before it is used.

Turbots, and all the rays, are extremely delicate in their choice of baits; for if a piece of herring or haddock has been twelve hours out of the sea, and then used as bait, they will not touch it. Pennant's Brit. Zool. vol. iii. p. 254, &c.

**TURBOWKA**, in Geography, a town of Russia, in Poland; 32 miles S.E. of Zyтомiers.

**TURBUNNY**, a town of Napaul; 60 miles S.W. of Catmandu.

**TURQUE**, in Ancient Geography, the name of a people who inhabited the environs of the Palus Mætides, according to Pomponius Mela. See **TURK**.

**TURCHANS**, or **ROOHANS**, in Zoology, a kind of wild hordes in the great defect about Azof. They are higher than the *tarpan*, (which fey,) mofs-grey in colour, with long upright standing ears, their manes and tails thinner and shorter than the common breed, their coats long and thick. They feed by thousands together in one taboo. The Kirghis Rhaifaks shoot them with guns, and eat them.

**TURCICA SELLA.** See **SELLA**.

**TURCICA TERRA, Turkey Earth,** in the Materia Medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent, and famous among them in pellential diseases. It is sometimes brought over to us also made up into flatish or bulbous masses, of two or three drachms weight, and fezled with some Turkish characteris. The earth is of a somewhat lax and friable texture, yet considerably heavy, of a greyish-red colour, but always redder on the surface than within; extremely soft, and naturally of a smooth surface. It breaks easily between the fingers, and melts freely in the mouth, with a considerably strong astringent taste. It adheres but slightly to the tongue, raves no effervescence with acids, and burns to a dulky yellow colour. Hill.

Many authors who have written of the materia medica, and of fofils in general, have indiscriminately called the various kinds of Lemmian earth by this name; but the true terra turcica, described by Schroder, Wormius, &c. is a different substance, though not sufficiently characterised by those authors to distinguish it from all the other earths.

**TURCKHEIM**, in Geography, a town of Germany, in the lordship of Mindelheim; 6 miles E. of Mindelheim—Alto, a town of France, in the department of the Upper Rhine, formerly imperial; 3 miles W. of Colmar.

**TURCKHEIM Rhein**, a town of France, in the department of Mont Tonnerre; 4 miles N. of Worms.

**TURCO**, a town of Peru, in the diocese of La Plata; 60 miles E.N.E. of Atacama. S. lat. 20° 30'. W. long. 68° 20'.

**TURCOCORIA**, a town of European Turkey, in Livadia; 14 miles N. of Livadia.

**TURCOIN**.
TURCOIN, a town of France, in the department of the North, and chief place of a canton, in the district of Lille. The unfortunate conflict between the French and the duke of York, who commanded the allies, may be said to have decided the fate of the Netherlands; 6 miles N.N.E. of Lille.

TURCOIS, or TURQUOIS, in Natural History and Mineralogy, a substance found in Persia and other parts of Asia, and formerly claffed with stones. It has a beautiful light-green colour, and is fusceptible of a high polish. The surface is smooth and polished; it has also a smooth shining fracture, and is so hard as to scratch glass lightly; the specific gravity is 3.127. It has for a long time been considered as the tooth of an unknown animal impregnated with copper; but by a series of analytical experiments, La Grange has proved that it does not contain a particle of copper; but is in reality bone coloured by phosphat of iron. The constituent parts are as under:

- Phosphate of lime
- Carbonate of lime
- Phosphate of iron
- Phosphate of magnesia
- Alumine
- Water

Guyton Morveau suspected that the turcois contained silex, but this is supposéd by other chemists to have been accidental. This celebrated chemist made some experiments on silex bones, and found that they assume in the fire the colour of turcois; and when digested in a weak solution of potash, they turn blue, varying from a greenish to deep blue. Mehrs. Fourcroy and Vaquelin have also observed that bones strongly calcined often assume a blueish tinge, which they considered to be caused by a small portion of phosphat of iron.

Turcois is employed in jewellery. See GEMS.

The Greeks and Latins seem to have known it under the name callaitz; and it appears to have had a place in the rational of the high-priest of the Jews.

Some writers mention turcois both oriental and occidental, of the new rock and of the old. The oriental part takes more of the blue tincture than the green; and the occidental, more of the green than the blue. Thofe of the old rock are of a finer blue, and thofe of the new rock are often whitish, and do not keep their colour.

The oriental ones come from Persia, the Indies, and some parts of Turkey; and some even suppoze, that it is hence they derive their modern name turcois. The occidental are found in various parts of Europe, particularly in Germany, Bohemia, Silefia, Spain, and France.

Turcois are found of a round or oval figure; they cut easily, and besides seals, which are frequently engraved on them, some are formed into crucifexes, or other figures, near two inches high; though De Boedt mistakély affirms, that none have been known to exceed the bigness of a walnut; for the specimen exhibited by Mr. Mortimer to the Royal Society was twelve inches long, five inches broad, and in some places near two inches thick.

The turcois is easily counterfeited; and that often is done so perfectly, that it is impossible to discover the deceit, without taking it out of the collet.

In the Memoirs of the Academy of Sciences for the year 1715, we have a very curious account of the formation of the turcois, and the manner of managing its naturally irregular colour, by M. Reaumur. The turcois, he obserues, is one of the safest of precious stones, its hardnes is not coming up to that of a crystal, or a transparent pebble; though some are much harder than others: and still the harder, ceteris paribus, the more valuable, by reason of the vivacity of the polish, which is always proportionable to the hardnes.

Reaumur, a jeweller, and the author of a scarce treatise, called Mercure Indien, estmating the several precious stones, noted a hard turcois, whose blue is neither bright nor deep, on the foot of the most perfect emeralds, that is, nearly on a level with a diamond; but such are scarcely ever met with. Thofe with any defect, he only values at a French crown the carat.

Tavernier affirms, but erroneously, that there are but two mines of turcoises known in all the earth, and these are both in Persia; the one called the old rock, near a town called Necabourg, three days' journey to the north-east of Mached; the other, called the new rock, is five days' journey from it. The stones from the latter, he adds, are but little valued; and the king of Persia hath for many years prohibited the digging in the former for any but himself. M. Reaumur takes the old rock to be now exhausted; in effect, the common division of turcoises into the old rock or oriental, and new rock or occidental, is very arbitrary and precarious. All the blue, and most perfect, wherever they occur, in India and China, are reckoned among the former, and the rest among the latter. Near Simore, in the Lower Languedoc, there are several considerable mines of turcoises; but that fine blue colour, admired in the turcois, is not natural to those of these rocks; the prevailing colour being sometimes white, and sometimes much like that of tripoli of Venice. Other precious stones are dug out of the mine with all their colour, to the force of which nothing can be added, though it may frequently be diminished, as we see fire bring down the too deep colour of the fapphire, and quite take away that of a pale fapphire; these turcoises, on the contrary, are naturally whitish or yellowish, of a colour as ordinary as that of a free-stone; and by opposing them for some time to the action of the fire they assume a blue colour.

It seems paradoxical, and yet M. Reaumur has attempted to prove, that turcoises are originally the bones of animals. In the mines in France, pieces have several times been found in the figure of teeth, bones of the legs, &c. And turcoises which are yet imperfect, or half-formed, are apparently composed of lamine, or leaves, like those of bones, between which some petrifying juice, infaminting itself, binds them clofe together; and full, the fofeter, the more imperfect the fones are, the more dillinguifhable are the different directions of the fibres and lamine, with their interferences, and the great refemmblance they bear to fratured bones, and the lefs to any kind of ftones known.

To give them a blue colour, they dry them awhile in the air, then heat them gradually in a furnace made after a particular manner. If they be heated too hastily, the humidity between the lamine wanting time to evaporate, the whole will separate into scales or flaws. Some of the stones require a greater degree of heat to bring them to their colour than others; and even in large pieces, the several parts ordinarily require several degrees of heat.

On this account a great deal of care is to be taken in the heating of them; for the fire, which gives them their blue by degrees, if they be expoed beyond a certain degree, takes it away again.

M. Reaumur accounts for their taking a blue colour by heat very well: when fresh cut out of the rock, it seems their subsistence is found sprinkled and streaked all over with spots, veins, little circles, &c. of a dark blue colour; thofe he takes to be fource of a deep blueish matter, which the fire rareifying, 3 G
rarefying, spreads and diffuses throughout the whole sub- 
stance of the fone. This matter, again, he concludes to 
have been either originally the juice contained in the bones, 
since mixed and coagulated with the petrifving juice, or 
some other mineral matter insinuated into the pores of 
the fone.

According to M. Reaumur's Mem. Par. 1715, nitrous 
acid will not dissolve that of Perfia, though it will that of 
France, which shews a difference between them.

Dr. Woodward maintains, that the turcois, or callais 
of Pliny, is nothing else but foffile ivory tinged with copper; 
but Mr. Mortimer, who produced a specimen of the turcois 
to the Royal Society, is of opinion, that fole which authors 
call stones of the old rock, and in which the colour is 
permanent, are real mineral fones; the form and fize of 
the faniple which he produced evincing this; for its fhape 
shews that it could not be part of any animal bone, but its 
botryoid form f eens to prove, that it is the production of 
fire, which has once melted this fubftance, and that when it 
cooled, its surface was formed into blisters and bubbles, in 
the fame manner as the lematites botryoides, or blood-
flone, whose surface confirts of knobs, reflenting a bunch 
of grapes. He apprehends the dephts iverco, or ehar 
flaff of Theophratius, to be what Dr. Woodward calls the 
turcois, and fuppofes that it is what De Bood calls the 
new rock. He thinks that, for diftinction fake, all these 
flones of ivory origin should be called pseudo-turcofis, or 
baulfard turcois. By a chemical analysis he concluded, that 
his flone was a rich copper ore; fome of it pounded and dif- 
folved in fpirit of hartthorn gave a deep blue; in aqua 
fortis, a fine green; and an iron wire put into it was in an 
hour's time incrulfed with copper; fome of it, being cal- 
cined without any flux in a crucible, ran to a flag or half-
vitrified fubftance; whereas the fame heat, if it had been 
ivory or bone, would have reduced it to a white ash, like 
bone-afhes, for it was expos'd to a fire that vitrifled the 
tile which covered it. Its hardnefs and confiftence to an 
graver's tool feemed to be the fame as that of common 
white marble; its colour was not improved by heat, and it 
became brittle when red-hot.

Sir Hans Sloane had feveral fpecimens of thefe oriental 
turcoifes, which are all botryoid, and feme to be copper 
ores; and in his museum there are alfo famples of turcoifes 
from Spain and the fouth of France, which are fmall, and 
feme to be pieces of ivory tinged with copper. Phil. Tranf. 
vol. xlv. art. 17.

The great defect of turcoifes in general is, that in time 
they lose their blue colour, and become green; and then 
ceafe to be of any value.

The pale blue of the natural turcois gem, is a very fa- 
vourite colour in the glafs-trade, and is given to glafs in 
the following manner. Firft calcine common fea-falt, and 
beat it into fine powder; then make a pot of the sea-green 
glas, of a fair and full colour; to this, when in fufion, 
throw in at times the powder of falt, till the fubs has loft 
all its tranparence, and is become paler and opaque; then 
add, by very small quantities at a time, more and more falt, 
till the colour is exaftly that of the turcois gem; and when it 
is fo, work it immediately, for the falt isfoon burnt off, 
and the glafs becomes tranparent, and of its green colour. 
If it become tranparent while working, more falt must be 
thrown in, and that will reduce it to the fame opacity again.

Neri's Art of Glafs, p. 57. See Glass.

For making a pate relluming the turcois, fee Paste.

TURCZYNKA, a town of Poland, in Volhynia; 38 
miles N. of Zytomiers.

TURDE, in Ancient Geography, a town of Italy, 
belonging to the Velumbrì, according to Ptolemy.

TURDETANI, or Turdetans, a considerable people 
of Spain, in Betica, a great part of which they occupied. 
The Turdetans were confidered as the moft diftinguifhed 
people of Spain. They studied their language; they were 
in poffeffion of ancient histories, and of laws written in 
verfe; they were regarded as the moft polished people of the 
whole province, on account of the commerce which they 
carried on with foreigners, and particularly with the Phcenicians.

When the Phcenicians fift landed on the coasts of Turde- 
tania, they found filver fo abundant, that all the moveables 
of the inhabitants, not excepting the meaneft and moft tri- 
ivial, were made of this metal. Strabo fays, that when the 
Turdetani became fubject to the Romans, they fuffered the 
manners of their conquerors, and forgot their own language, 
adapting that of the Romans. Their provinces furpafed all 
others in riches and cultivation, in honesty and religious zeal. 
This country supplied great abundance of cheefe, wine, oil, 
wax, faflon, vermilion, &c., particularly fine wool.

TURDULI, a people of Spain, in Betica, towards the S.E. 
According to Strabo, the Turduli and Turdetani 
were the fame people.

TURDUS, Thrush, in the Linnean Syfen of Ornitho- 
logy, the name of a genus of birds, of the order of the 
Faferes. The diftinguifhing characters of this genus are, 
that the tongue is jagged, and has a rim or margin round it; 
the bill is of a conic-pointed figure, the upper mandible 
bent at the apex, and emarginated; the noftils naked, but half 
covered above with a small membrane, and the chops ciliated.

Gmelin enumerates 125 

Species.

VISCIVORUS. With a brown back, neck with white spots, 
and a yellowish bill. This is the millif thrush of Pennant 
and Latham. Found in the woods of Europe.

PILARIS. With black tail-feathers, the outer moft whitifh 
at the apex and interior margin, the head and rump hoary. 
The fieldfare of Ray, Willughby, Pennant, and Latham. 
Of this there are four varieties. Found in the woods 
of Europe, Siberia, and Syria.

AFRICANUS. Blackifh, the breast covered with black 
feathers, with red margins; the bill yellow; and the legs 
cicereus. Found in Africa.

TRIPOLITANUS. Olive-yellow, whitifh beneath; black 
quills; equal blackifh tail and yellow apex. The Tripoli 
thrush of Latham. Found in Barbary.

BARBARICUS. Green; breast spotted white, rump 
and tail at the tip yellow. The green thrush of Shaw's 
Travels, and the Barbary thrush of Latham, fo called from 
itf habitation.

AONALASCHINUS. Brown spotted black; the breast 
yellow spotted black; the wing-coverts, the greater 
quills and tail-feathers black, with a teftaceous margin. 
The Unalafha thrush of Pennant, and Aonvalafhka thrush 
of Latham, fo called from the place of its abode.

ILIASCHUS. With wings ferrifugious beneath, and whitifh 
eye-brows. The red-wing, fwine-pipe, or wind-thrush of 
Ray, Willughby, Pennant, and Latham. An European 
bird, migrating in large flocks.

MINOR. Light-red, beneath white; breast yellowifh, 
varied with black spots. The little thrush of Pennant, Ed- 
wards, and Latham. Found in Jamaica and North America; 
seven inches long, migrating and feeding on berries.

JAMAICENSIS. Above Cicereous; bill, head, and legs 
brown;
brown; quill-feathers and tail black; chin and throat white, fritated with brown; breast cinereous; abdomen white.

The Jamaica thrush of Latham.

**Guanensis.** Above greenish-brown, underneath ochre-coloured, with black longitudinal line. The Guiana thrush of Latham.

**Muscicus.** With quill-feathers at the inner base ferruginous. The Mavis thrush or long-thrush of Ray, Wilugby, Pennant, and Latham. Found in the woods of Europe, imitating in the mornings of spring the song of the nightingale, and continuing it for almost nine months. Of this there are three varieties.

**Olivaceus.** Brownish; beneath yellow. Found at the Cape of Good Hope.

**Indicus.** Olive-coloured; bill and legs blackish; quills brown on the inner side. The Indian thrush of Latham; so called because it is found in India.

**Cinererus.** Ash-coloured, with the two intermediate tail-feathers cinereous; the next on both sides black at the margin, and cinereous at the apex; the rest black. The ash-coloured thrush of Latham. Found in India.

**Migratorius.** Grey; abdomen red; eye-lids white; the external tail-feather white at its interior apex. The American fieldfare of Forrer, and red-breasted thrush of Latham. Found in North America, from Hudson’s Bay as far as the bay of Natka and Carolina.

**Trichas.** Olive-coloured; the body beneath yellow; the ocular band black. The Maryland yellow-throat of Edwards, and the yellow-breasted warbler of Pennant and Latham. Found in summer in the moist low woods of Carolina, Maryland, and Pennsylvania.

**Canorus.** Brown; beneath ferruginous; with a white line on the sides of the head, and a rounded tail. The crying thrush of Latham. Found in Bengal and China.

**Rufus.** Red; beneath spotted whitish, with quill-feathers of the same colour; the tail rounded and red. The ferruginous thrush of Pennant and Latham. Found in America, from Newfoundland to Carolina.

**Polyglottus.** Obscurely ash-coloured; beneath palely ash-coloured, with the greater quill-feathers white on the exterior half. The fingling-bird, mocking-bird or nightingale of Sloane, the mock-bird of Catesby and Kalm, and the mimic thrush of Pennant and Latham. Found in Jamaica, and the moist woods of America, practising in the way which its name imports.

**Orphius.** With brown back; breast and lateral wing-feathers whitish; eye-brows white. The polyglott bird of Willughby, the lesser mocking-bird of Edwards, and the mocking-thrush of Latham. Found in Jamaica, and the warmer parts of America. It has two varieties.

**Sandwichensis.** Above and abdomen brownish; beneath and front cinereous-white. The Sandwich thrush of Latham. Found in the Sandwich islands.

**Pacificus.** Above cinereous; beneath brownish-white; the lori black; the tail black, with a white tip. The Pacific thrush of Latham. Found in the Friendly islands.

**Suratensis.** With the head somewhat crested; the neck, tail, and greater quill-feathers and legs black; the body above amber-coloured; beneath dirty-grey; the wing-coverts and second quills green. The Surat thrush of Latham, named from its habitat.

**Philippines.** Above olive; neck and breast red, spotted with white; abdomen and vent ochre-coloured. The Philippine thrush of Latham; so called from the islands which it inhabits.

**Shanru.** With chin, throat, and the ocular area black, with a large white streak at the ears; the rest of the head, neck, breast, and abdomen grey; the back and wings greenish-brown. The black-faced thrush of Latham. Found in the woods of China.

**Nov. Hollandiz.** Bluish lead-coloured; the anterior part of the head, the bill, chin, throat, and legs black; the quill and wing-feathers black, with lead-coloured margin; the intermediate white at the apex. The New-Holland thrush of Latham.

**Plumbeus.** Black, with yellow axillar, and cuneated tail. The red-legged thrush of Pennant and Latham. Found in North and South America, and in the Bahama islands.

**Crassirostris.** Above from red, and beneath from black to brown, with the quill-feathers acuminate; the two intermediate obscure. The thick-billed thrush of Latham. Found in New Zealand.

**Ultrics.** From red to brown; quill-feathers black at the margin, and roundish tail black. The Bay thrush of Latham. Found in Ulieta.

**Pallidus.** From yellowish to ash-coloured; beneath whitish; tail-feathers from cinereous to brown; the side ones white at the apex. Pale thrush of Latham. Found in Siberia, beyond the lake Baikal.

**Sibericus.** Black, with yellow mouth; eye-brows and space under the wings white. White-browed thrush of Latham. Rare in the alpine and more northerly woods of Siberia.

**Ruficolliis.** Above brown, below snow; neck and equal tail-feathers red; the two intermediate cinereous. Red-necked thrush of Latham.

**Obscurus.** Brown; with eye-brows, chin and vent blue. Dark thrush of Latham. Found beyond the lake Baikal, in the woods of Siberia.

**Pheniculus.** Above olive, with white eye-brows; ocular band black; tail-feathers and two intermediate quills palaceous; sides with throat and breast red. The red-tailed thrush of Latham. Found at the Cape of Good Hope.

**Rupicolaus.** Above olivaceous; beneath purplish and white; tail-feathers and quills black; sides for the most part red. The rufous-tailed thrush of Latham. At the Cape of Good Hope.

**Malabaricus.** Ash-grey; beneath red-brown; bill and tail-feathers black; legs yellow. The Malabar thrush of Latham. Found in Malabar.

**Pagodarum.** Black; back and rump grey; vent white; head crested. The pagoda thrush of Latham. Found in Malabar and Coromandel.

**Cayennensis.** Cinereous; beneath whitish; vent white; greater wing-feathers and tail-feathers black; throat, bill, and legs black. The Cayenne thrush of Latham.

**Variegatus.** Above brown; beneath whitish; feathers whitish and black intermixed. Variegated thrush of Latham. Found in Surinam.

**Striatus.** Varied with yellow and grey; a longitudinal streak of the back yellow. Yellow-backed thrush of Latham. Found in Surinam.

**fuscus.** Olivaceous-brown; breast and abdomen whitish, spotted with brown; greater quills and legs black. Brown thrush of Latham and Pennant. In New York.

**Mustelinus.** Beneath white, spotted with black; cheeks brown, spotted with white; rump and greater quills acuminate, and tail-feathers brown. The tawny thrush of Latham. In New York.

**Camtschatkenis.** Brownish; beneath from brownish to white; eye-brows pale; chin and throat carophyllous-coloured. Kamtschatka thrush of Pennant and Latham. Found in Kamtschatka.
TURDUS.

NAEVUS. With head and pectoral band black; streak from the eyes to the hind part of the head ferruginous; body above cinereous; beneath ferruginous. The varied thrush of Pennant, and spotted thrush of Latham.

Hudsonicus. From bluish to cinereous; bill and legs black; feathers of the crown, nape, wing-covers and primary quills pale at the margin, red. The Hudsonian thrush of Pennant. Found in Hudson's Bay.

Novemrachnus. With head, neck, and breast varied from black, and dilutely ferruginous; feathers of the back ferruginous at the margin; with double band above and below the eye, wings, and roundish tail shining-green, and legs black. The New York thrush of Pennant. Found in New America.

Curucus. Shining-black; bill sub-filibrated, and tail emaciated. Found in Chili.

Nitens. Green; spot on the wing-covers violet. Shining thrush of Latham. Of this there is a variety, the green merula; beneath violet; throat and rump blueish. Found in Angola, and at the Cape of Good Hope.

Æneas. Shining-green; beneath brassy; head blackish to shining-gold; rump and intermediate tail-feathers purplish; tail wedge-formed. Glossy thrush of Latham. Found in Senegal.

Auratus. Violet; back and wings green-gold; band of the wings at the internal margin and tail, with the superior wing-covers, blue. The gilded thrush of Latham. Found at Whidah, in Africa.

Leucogaster. Violet; with white belly; blackish quills; bill and legs cinereous. The Whidah thrush of Latham.

Roseus. Subincarnate; head, wings and tail black; occiput crested. Merula roeae of Aldrovand, Ray, and Brifson; rofe or carnation-coloured ouzel of Pennant, Wilughby, and Edwards; the rofe-coloured thrush of Latham. Found in various parts of Europe, Siberia, and Syria, migrating in flocks, and feeding chiefly on locusts.

Leucurus. Black; rump and tail white; tail-feathers black at the apex. White-tailed thrush of Latham. Found about Gibraltar.

Caper. Blackish; somewhat crested; rump and belly white; vent red. Cape thrush of Latham. Of this there is a variety, the merula above brownish to cinereous; filiated brownish; beneath hoary. Found in China, and at the Cape of Good Hope.

Macrorurus. From purplish to shining-black; beneath from ferruginous to yellow; rump and three tail-feathers on both sides exteriorly white. The long-tailed thrush of Latham. Of this there is a variety with the two intermediate tail-feathers black; the rump half white. Found in Pulo Condore and Malabar.

Amboinensis. Spadiceous; beneath yellow; secondary quill-feathers yellowish from the base to the middle; tail cuneiform; beneath yellow. The Amboine thrush of Latham.

Boronicus. From cinereous to olive; black crown; abdomen and vent from olive to yellow; tail brown, with two obiolute bands towards the apex. The Bourbon thrush of Latham. Found in the island of Bourbon.

Ochroccephalus. With the larger quill-feathers, tail, and legs green; vertex and checks yellowish; collars black; abdomen and breast cinereous; the latter varied with fagi tinted spots. The yellow-crowned thrush of Latham. Found in Ceylon and Java.

Orientalis. Black; beneath white; rump cinereous; ocular band black; three tail-feathers on both sides externally white. Ash-rumped thrush of Latham. In India.

Nigerrimus. Wholly black; feathers yellow at the margin; cheeks and throat holofuscous. The black-cheeked thrush of Latham. Found in Madagascar.

Hispianolensis. Olive-coloured; beneath varied from olive to grey; brown tail-feathers, whith at the interior margin, olive at the exterior; with the intermediate altogether olive. The Hispaniola thrush of Latham.

Albifrons. From black to lead-coloured; beneath yellowish; with the spot on the front white; and brown legs. The white-fronted thrush of Latham. There is a variety black; beneath white, rump beneath cinereous. Found in New Zealand.

Capensis. Brown; abdomen yellowish; vent yellow. A variety has the head and tail black. Found at the Cape of Good Hope.

Atropicillus. Brown; head black; abdomen and rump red; spot on the wing white. Found at the Cape of Good Hope.

Mauritianus. From greenish to deep blue; the feathers of the head and neck narrow and long; bill cinereous; and legs lead-coloured. The Mauritius thrush of Latham.

Mindanaensis. Steel-coloured; beneath white; the longitudinal band of the wings white; tail subfuscated. The Mindanao thrush of Latham.

Madagascarensis. Brown; abdomen and vent white; tail subfuscated; two intermediate tail-feathers wholly, and the rest at the exterior margin green-gold; the exterior margin of the outmost on both sides white. The Madagascar thrush of Latham.

Senegalensis. From grey to brown; abdomen whitish; bill, tail-feathers, tail and legs brown. The Senegal thrush of Latham.

Longirostris. From olivaceous to pale-brown; beneath pale sulphureous; rump and eye-brows yellowish; tail round and yellow; intermediate tail-feathers brown. The long-billed thrush of Latham. Found in the islands of Eimeo and York.

Griseus. Grey; crown and neck whitish, breast, abdomen and vent from very pale red to grey. The grey thrush of Latham. Found in Coronadel.

Palmarum. Green-olivaceous; beneath sub-cinereous; black head, with three white spots on each side. The palm thrush of Latham. There is a variety, viz. merula palmarum atricapilla; found among the palms of Cayenne.

Monachus. Above yellow, with brown; beneath yellowish; black head; terminating with black on the breast acutely. The nun thrush of Latham. Found in the woods of Abyssinia.

Æthiopicus. Black; beneath white; with a transverse white band on the wings; tail round, tail-feathers quadrated at the apex. The Ethiopian thrush of Latham. Found in the thick woods of Abyssinia.

Abyssinicus. Brown; beneath yellow; brownish throat, and black legs. The Abyssinian thrush of Latham.

Cochinchinensis. Green; with blue spots on both sides at the base of the bill; face, chin, and throat black; the latter encompassed with a yellow arc. Found in Cochinchina.

Cinammomeus. Beneath more diluted cinnamon; throat, legs, temples, cheeks, chin, covers of the wings, and breast black; with white nebulous wreath. The black-breasted thrush of Latham. Found in Cayenne.

Rufifrons. Brown; beneath, and the front and temples red; vent white; tail and legs cinereous. The rufous thrush of Latham. Found in Cayenne.

Cantans. From red to brown, varied with transverse black or blackish streaks; beneath whitish; chin, cheeks, and
and throat from red to orange; with black area, spotted with white on both sides of the neck. **Mutilated thrush of Latham.** In the recesses of the forests of Cayenne.

**Coraya.** Red-brown; beneath more dilute; vertex and sides of the head and neck black; tail grey, varied with blackish lines. The barred-tailed thrush of Latham.

**Fuscipes.** Cinereous; beneath red; vertex black; legs and tail-feathers brown; tail sub-cuneated. The buff-winged thrush of Latham; suffixed to be found in Cayenne.

**Alapi.** From olive to brown; throat and breast black; abdomen cinereous; tail wedge-formed, blackish. The white-backed thrush of Latham. In Guiana.

**Chirriatus.** Cinereous, with wedge-formed tail, white at the margin and apex; crested crown; throat varied with white and black; breast black. The black-crested thrush of Latham. Found in Cayenne.

**Tintinnabulatus.** Vertex and temples white, spotted with black; eye-brows black; chin white; incarnated breast spotted with black; back, wings and tail brown; rump, abdomen and vent from red to orange. The chiming thrush of Latham. Found in Cayenne and Guiana.

**Bambia.** Spotted; above from red to brown; beneath cinereous; wings black; with a white transverse band. The black-winged thrush of Latham. Found in Cayenne.

**Auritus.** Varied from red and olive-coloured; beneath white; vertex and wrass from red to brown; chin and throat black; feathers near the eyes, and at the sides of the neck, thining-white; elongated and more wide. The white-eared thrush of Latham. Found in Cayenne.

**Colma.** From red to brown; beneath cinereous; chin and throat white, spotted with black; breast from grey to brown. The rufous-naped thrush of Latham. It has a variety from brown to black; the occiput and neck red. Found in Cayenne.

**Tinniens.** Above brown; beneath white; breast spotted with black; equal tail. The alarum thrush of Latham. Found in Cayenne.

**Lineatus.** From olive to brown; chin, throat and breast white; the latter spotted with brown; the sides of the neck marked with white lines. The speckled thrush of Latham. Found in Cayenne.

**Formicivorus.** Above from red to brown; beneath cinereous; chin, throat, and breast black; band varied with white and black. The ant thrush of Latham. Found as the former.

**Cyannus.** Spadiceous; beneath varied with blue and yellow transverse alternate streaks; vertex at the nape to the quill-feathers and ocular band black; another orange; pec-toral band and wedge-formed tail blue. The blue-tailed thrush of Latham. In Guiana.

**Rex.** From red to brown; beneath more dilute; occiput head-coloured; front varied from white to brown. The king thrush of Latham. Found in South America, particularly Guiana and Brafil.

**Sinensis.** Reddish; head brown frigated; white eye-brows; tail-feathers marked with obscure brown streaks, and legs yellow. The Chinese thrush of Latham. Found in China.

**Trogatus.** Above spadiceous; with eye-brows, collars, chin and vent white; cheeks and bow of the throat white; tail rounded; black towards the apex; apex white. The crested thrush of Latham. Found in China.

**Metallus.** Above spadiceous; with eye-brows, collars, chin and vent white; cheeks and bow of the throat white; tail rounded; black towards the apex; apex white. The crested thrush of Latham. Found in China.

**Melanopus.** Grey; back and wings from green to brown; orbit, chin, and throat black; spot on the ear white. The black-faced thrush of Latham. In the woods of China.

**Violaceus.** From violet to blue; feathers of the head, neck, breast, and covers of the wings steel-faciated at the apex; bill and legs black. Found in China.

**Leucocephalus.** Grey; black quill-feathers; the lesser with the covers of the wings and tail green-brally and thining-violet. The white-headed thrush of Latham. In China.

**Nigricollis.** Brown; head, chin and nape white; ocular band and breast yellowish; neck, back and tail-feathers black; tail wedge-formed, head-coloured. The black-necked thrush of Latham. Found in China.

**Bubil.** Of the colour of terra umbra; longitudinal band near the eyes black. The chanting thrush of Latham. Found in the southern part of China.

**Perspicillatus.** With head and neck cinereous; front and breast under the eyes on both sides black; body above from greenish to brown; beneath ochroleucus. The spe-culate thrush of Latham. In China.

**Flavus.** Yellow; white orbits; band from upper mandible produced near the eye black; bill and legs red. The yellow thrush of Latham. In China.

**Viridis.** Green; with eye-brows, spot below the eye, abdomen and vent white; throat grey, spotted with white; breast reddish. The green thrush of Latham. In China.

**Ater.** From grey to brown; beneath from greenish to yellow, spotted with black; bill, legs, front, face, chin, and throat black; the latter with a red margin. The black-throated thrush of Latham. In the island of St. Domingo.

**Dominicus.** Brownish; beneath white; with the principal tail-feathers white at the base; the three outer tail-feathers white. The St. Domingo thrush of Latham. Found in St. Domingo and Jamaica.

**Braelliensis.** Black; beneath from ferruginous to yellowish; ramp ferruginous; tail sub-cuneated; outermost tail-feathers wholly, the rest at the apex, white. The yellow-bellied thrush of Latham. Found in Brazil.

**Merula.** Black; with bill and eye-lids yellow. The blackbird of Pennant, Ray, Willyughby, and Latham. Of this there are the varieties of *merula leucocephala* of Briffon, *merula varia* of the fame, or pied blackbird of Albini, and *merula alba* of Griffon. Found in the woods of the temperate parts of Europe.

**Aurantius.** From blackish to brown; throat and abdomen whitish; bill and legs orange-coloured. The thrush of Sloane and Ray; the white-chinned thrush of Latham. The varieties are, *merula gula fusca, merula nigra, and merula americana*. Found in the woody mountains of Jamaica, in New Caledonia, in Surinam, and the warmer parts of America.

**Labradorus.** Shining-black; with a blue and green tint; bill and legs black. The Labrador thrush of Pennant and Latham.

**Torratus.** Blackish, with a white wreath, and bill yellowish. The ring-nosed or amulet of Pennant, Ray, Willyughby, Albinius, and Latham. The varieties are, *merula torquata alba, merula torquata albo-maculata, merula albo-maculata, non torquata*. Found in Europe, Asia, and Africa.

**Saxatilis.** Brown; beneath dorally orange, undulated with brown and white; ramp ferruginous; chin white; throat and intermediate tail-feathers brown, the latter in the margin side ones wholly orange. The greater redstart of Willyughby, and rock thrush of Latham. Found in Italy and Spain.

**Erithaca.** With whitish orbits; olivaceous vertex; the upper feathers of the occiput brown, near the whitish apex black-blended, and the lower ones from red to white; brown at the margin; and cinereous rump. The hermit thrush of Latham. Found in the Philippine Isles.
MANILLENSIS. From cinerea to blue; blue rump; tail-feathers and tail red at the margin, blackish; throat and breast spotted with yellow; abdomen orange-coloured, undulated with blue and white. The penive thrush of Latham. Found in the Philippines.

SOLITARIUS. Brown; spotted for the most part with whitish; and blackish tail. The solitary sparrow of Ray and Willughby, and solitary thrush of Latham. Found in France, Italy, and the islands of the Mediterranean and Archipelago.

Cyanus. With feathers cinerea-blue at the margin; mouth and eye-lids yellow. The Indian mockbird of Ray, the solitary sparrow of Edwards, and blue thrush of Latham. Found in Canda, the Archipelago islands, and the rocks of Italy.

ARUNDINACEUS. Brown-ferruginous; beneath whitish-tefaccous; with tail-feathers banded and reddish at the apex. The junco of Gofner, Aldrovand, Ray, and Willughby. The varieties are T. arundinaceus, with red rump and tail; t. arund., above varied with black darts; and least T. arund., above from yellowish to green; with covers of the wings ferruginous. Found among the reeds of Europe.

Morio. Shining-black, with the greater tail-feathers red, and apex black. The African thrush of Latham. Found at the Cape of Good Hope.

Bicolor. Brown tinted with green; abdomen and vent white. The white-rumped thrush of Latham. Found as the former.

ERYTHROTERUS. Black, with red wings; wing-covers and lower quill-feathers of the tail, the intermediate excepted, white at the apex; tail wedge-formed. The rufous-winged thrush of Latham. Found near the Senegal river.

CHRYSOGASTER. Green tinted with orange; beneath orange; bill and legs brown. The orange-bellied thrush of Latham. A variety is from blue to green; beneath orange. Found near the river Senegal, and at the Cape of Good Hope.

Orovang. Cinerea; vertex greenish-black; rest of the head, neck, breast, and body above varying to olive-coloured; the abdomen and crest yellowish. The cinerea thrush of Latham. Found in Madagascar.

Surinam. Shining-black; vertex, rump, and lateral spot on the breast yellow. The Surinam thrush of Latham.

Columbinus. Green, reflecting different sorts of colours; the rump and vent sometimes white. The pigeon thrush of Latham. Found in the Philippine isles.

Dominicanus. Above brown; here and there tinted with violet and feathere; beneath from brownish to white; tail-stip-coloured at the base, greenish towards the apex. The Dominican thrush of Latham. Found in the Philippine isles.

Cantor. From greenish to black, shining-blue and violet; with tail-feathers and tail black. The fonger thrush of Latham. Found as the former.

Malabaricus. Shining-green; yellow front; throat, bill and legs black; covers of the wings and streak on the lower mandible blue. The yellow-fronted thrush of Latham. Found in Malabar.

Seleucia. With bill and legs yellowish; abdomen and back incarnate; tail, wings, and thighs brown. Found in Smyrna.

Zeylonus. Green; beneath yellow; ocular line on both sides extended as far as the black breast. The Ceylon thrush of Latham. Found at Ceylon and the Cape of Good Hope.

Turdus Aquaticus of Brisson. See Tringa Macularia.

Turdus Chiappa, the name of a bird of the West Indies, called also puffer fisher.

Turdus, in Ichthyology, the name of a genus of fishes, according to Mr. Ray, of the clafs of those which have only one back-fin, the anterior rays of which are prickly; the hinder ones soft and smooth.

Of these fishes there are several species, which may properly be divided into two orders; the first, of those which are smaller and broad; the second, of those which are larger and oblong.

Of the first order are the tinea marina, or wrasse (see Labrus Tinea) ; the merula, or turdus niger (see Labrus Merula); the leprous, and pira pira (see and the turdus viridis, or verdone. Ray's Ichthyogr. p. 332.

Of the second order are the pavo, or peacock-fish (see Calotodon Pavo); and the turdus viridis major, and turdus fusus maculosus.

The turdus viridis major, or great green wrasse, is of a fine green on its back and sides, even to the side-lines; and the lower part of the sides and belly are of a pale whitish yellow, variegated with greyish and pale blue spots; its body is long, and not much unlike that of the pike in figure; its back-fin is long, and has thirty-two ribs, the anterior nineteen of which are rigid and prickly, the hinder twelve soft, flexible, and ramose; the scales are large, the eyes small, and the teeth very large and strong.

The turdus fusus maculosus, or brown spotted wrasse, scarcely at all differs from the others, except in colour. It is of a dusky hue on the back and sides, variegated with blue spots; and on the belly blue, with lines and spots of red. All the fins, except those of the gills, are of a red colour, spotted with blue; the tail also is of this colour, and the gill-fins are yellow. Ray's Ichthyogr. p. 332.

Turdus Oculo Radiato of Catesby. See Sparus Radius.

Turdus Primoris Branfibia Caren. See Labrus Grifias.

Turdus Flavus. See Labrus Rafus.

TURECUATO, in Geography, a town of Mexico, in the province of Mechoacan; 60 miles W. of Mechoacan.

TUREE, a town of Bengal; 40 miles S.S.E. of Curuckedesh. N. lat. 24° 50'. E. long. 86° 56'.

TURENBERG, a town of Prufia, in Samland; 16 miles W.N.W. of Königberg.

TURENNE, Henry de la Tour, Viscount of, in Biography, a famous general, was the son of Henry de la Tour d'Anvergne, duke of Bouillon, by Elizabeth, daughter of William I. prince of Orange, and born at Sedan in 1611. Deigned from his childhood to the military profession, his education and habits were conducted and formed with this view. Having acquired the necessary qualifications, he was placed, in 1634, at the head of a French regiment, in which poft he acquitted himself with honour; and having pursued a career of distingushed services, cardinal Richelieu, in 1638, offered him one of his nieces in marriage; but his attachment to the reformed religion led him to decline the proposal. After he had served 17 years in Italy and elsewhere with singular reputation, he obtained, in 1644, the flaff of marshal of France, and was entrusted with the command of the army in Germany, the wants of which he supplied out of his own purse. When the war of the Fronde broke out in 1649, he withdrew to Holland, but afterwards returned and engaged with the party opposed to the court. In this connection he was defeated near Rhetel in 1650; and when asked how he had lost this battle, he replied, "By my own fault; but when a man commits no faults in war, it is because he has not been long engaged in it." In 1651 his difference with the French
French court was accommodated, and he was appointed general of the royal army. In 1653 he married the daughter of the marshal duke de la Force, a Protestant, by whom he had no issue. After several campaigns of alternate successes and defeat between him and d'Enghein, now prince of Condé, in the service of Spain, Turenne in 1657, having gained the battle of Dunes, captured Dunkirk from the Spaniards, and the greatest part of Flanders; so that Mazarin was enabled to make the peace of the Pyrenees. Upon a renewal of the war with Spain in 1667, Lewis XIV. made choice of Turenne, now marshal-general of the French armies, as his tutor in war; and the refult of the first campaign was the conquest of the greatest part of Flanders, and afterwards of Franche Comté. In the following year, Turenne, from motives not satisfactorily ascertained, but not reddening much to his honour, abjured Calvinism, and was reconciled to the church of Rome. In the year 1672, it was determined by Lewis to conquer Holland, and the command of the army was affigned to Turenne; to whose arms refilience was in the course of the campaign ineffectual. The elector of Brandenburgh, proposing to relieve the Dutch, was pursu'd to the gates of Berlin, and obliged to sue for peace. When at this time it was propofed to the marshal to gain 400,000 lives without the knowledge of the court, he thanked the general officer who made the propofal, and told him, that as he had often declined such advantages, he did not intend to alter his conduct at his age. On another occasion, a confiderable city offered him 100,000 crowns for not pafling through its territory; and his reply to the deputies was, "As your city is not in my propofed line of march, I cannot in confidence take your money." We fhould exceed our limits, if we detailed his various succelful movements during the following campaign. The foldiers reprofed confidence in their commander, and to this confidence he owed the profoperous issue of various expeditions. The glory of his conquests, however, was tarnifh'd by his cruel defcillation of the Palatinate, which Voltaire has juftly reprofected; observing at the clofe of his account, that "he rather chose to be called the father of the foldiers that were entruff'd to him, than of the people, who, according to the laws of war, are always made the facrifice. The imperial court, determined to make every effiffle effort to check the progres of Turenne, called for Monteculvi, its beef general, to oppose him. As these two masters of war were preparing for an engagement, Turenne, whilf he was reconnoifiring a fit place to fix a battery, on July 27, 1675, was struck by a cannon ball, which killed him on the spot, in the 64th year of his age; and with him terminated the good fortune of the French in that campaign. His remains were interred with the highest funeral honours at St. Denis. The greatnefs of Turenne's soul was difguifed by a rude and vulgar appearance. His temper was cool, and his manners modest and unafmiffing. He was not always fuccellful in war, and committed faults, which he had the magnanimity to acknowledge; but, as Voltaire fays, (Age of Lewis XIV.) "he always repaired them, and doing much with small means, he pafl'd for the ablest general in Europe, at a time when the art of war was more fludied than ever before. Though he was reproach'd for his defcifion in the war of the Frondë; though at the age of fifty six, love cauf'd him to reveal a fatfeheart; though he exercif'd cruelties in the Palatinate, which he deemed unneceffary; he preferred the reputation of a man of worth, wife and moderate, because his virtues and great talents, which were his own, covered weaknefs and failures which were common to him with fo many other men."

Ramfay, in his "Life of Turenne," mentions the following anecdote, as an infiuance of his ftrict performance of a promife. Being attacked one night by robbers near Paris, and riflped of his money, watch, and rings, he engaged to give them 100 louis d'ors, if they would return him a ring, of no great worth, but which he highly valued. The highwaymen complied; and one of them had the boldnefs to go to his houfe the fucceeding day, and in the middl of a large company to demand, in a whisper, the performance of his promife. The viccount gave orders for the money to be paid, and fuffered the villain to effcape, before he related the adventure.

Turenne, in Geography, a town of France, in the department of the Correze; before the revolution, the capital of a vifcounty; 9 miles S. of Brive.

Turevskoi, a town of Ruffia, in the province of Ufurg, on the Vim; 60 miles N.E. of Yarenk.

Turf, in Agriculture, a term often used to signify the green fward or surface of grafs-land. It is of great use and importance to the farmer to have the turf of fuch land clofe, firm, and well fet, as where this is not the cafe, it foam declines, grows thin, and becomes of little value either for the purpofe of moving or paffuring. It has been noticed, in the "Georgical Effays" of Dr. Hunter, in speaking of the improvement of the turf of poor pallure land, that, on fuch, it constantly gets worse a few years after having been laid down for that purpofe; the cafe of which is plainly this. There are a few fpyr grafles, natural to moft poor lands, which are denominated natural grafles; while thofe from the feeds of clover, and others of fimilar kinds, which are introduced, are in general termed artificial. The roots of these latter are not very durable, efpecially on poor land; and as the cattle as well as other forts of live-flock are greedy of fuch fown grafles, they constantly crop them, and prevent their going into feed, by which the land is deprived of frefh supplies of young plants; whereas the former fort, or the natural grafles, being, in general, much inferior to the other in quality, are refufed by fuch flock, and the land, confefiently, soon becomes plentifully stocked and provided with them.

It is fuggreffed too, that the general method of praftice for improving land, when the turf gets thin and bad, is to bring it under a course of tillage. But when that is not proper or convenient, or when the occupier of fuch land is not inclined to introduce that mode, it may be greatly improved by having fresh feeds of the grafs fot fown upon it; the beef fefon for which is in the beginning of the firft fpring month. The ground fhould firft be well wrought over with a heavy harrow of the plough kind, which will brin'h up and rafle the foil, and prepare it well for the ftriking of the feeds in it. Compofi earth fhould then be used as a dressing, and the feeds fown thereon: after which the ground may be lightly brufhed over again, and well roled. When the fefon proves moist and kind, the feeds will be found to thrive to admiration, and to wonderflully improve both the turf and verdure. And where the turf of land has been greatly cut up by carriages, or much trod up by cattle, it is alfo capable of being improved in this way, without the dressing of compofi earth. Even in paddocks where the turf of the land has been cut up to an extreme degree by rude and wanton horses, a new and verdant turf has been feen to arife, even to augmentation, in a few weeks after fowing the feeds. It is, however, neceffary that cattle should be prevented from coming upon the land until the turf get well fet, and in a firm flate.

The turf, in all forts of land, may be greatly benefitted by
TURF.

by the proper use of manure upon it, and at the same time properly feeding it down with suitable kinds of live-flock. See Grass, Grass-Land, and Grazing.

Turf is likewise a term applied to a blackish fibrous vegetable earthy sub stance, which is used in many parts of the country as fuel. It varies considerably in its nature and composition in different places, being, in some cases, hard and of a dark or black colour, while in others it is soft and very spongy, and of a brownish colour. It is cut and formed into turves for the purpose of fuel, by means of a particular form of instrument, employed in a certain manner. See Turfing Spade.

It is a sub stance which is not only very useful in this way, but for burning calcareous liones into lime, and many other purposes in agriculture.

Turf or peat-earth is capable of extensive use as a manure, but it mostly requires some preparation to properly fit it for this fort of application; as it is found that it is a sub stance which is held together partly by the intertexture of its fibres, and partly by its natural viscidity; and that when it is allowed to dry readily in that flate, it becomes almost incorruptible; and that it does not yield food to growing vegetables, unless its natural conformation be destroyed, and its parts separated by the intervention of other sub stances. This strongly flues that its structure or texture should be somehow broken down and reduced, and the water which it originally contains be forcibly discharged from it, as soon as possible after it is taken from its native bed, in order to prepare it for manure. There are different methods of effecting this. It has been suggested, that as this fort of fibrous matter will not ferment unless some sub stances are mixed with it, which act the same part as the mucilage, sugar, and extractive or albuminous matters, with which it is usually associated in herbaceous and succulent vegetables; a mixture of common yard-dung has been lately properly recommended for the purpose of bringing turf or peat-earth into fermentation; any putrefiable or fermentable sub stance will, however, answer the end; and the more a sub stance heats, and the more readily it ferments, the better it will be fitted for the purpose. In forming this mixture, it is flated, that one part of dung is sufficient to bring three or four parts of the turf or peat into a flate in which it is fitted to be laid upon land; but that, of course, the quantity must vary with the nature of the turf and the dung. In circumstances where some living vegetable mixtures are mixed with the turf or peat, the fermentation will be more readily accomplished.

Turf or peat of this fort, after being reduced in its parts, may also be prepared for this use by being soaked in the urine of cattle, in putrid water, and other such liquids; likewise by the action of lime, and by being ridged up and mixed in the manner below.

This material, both in mixtures with dung and lime, has been used with great success and advantage in Cheshire. The method of preparing it there, in the practice of fome, is, before the winter sets in, to trench and throw it up into narrow ridges, that it may be dried and reduced into a powdery flate by the action of the atmosphere. After some time it is turned over and laid flat, being then usually found much lighter than when first dug up. It is now covered over with dung, in the proportion of a fourth or fifth part of the weight, and left so for about three weeks, when it is turned over, mixed perfectly with the dung, and thrown into heaps. A fermentation commonly takes place, that varies in its duration in proportion to the moif ture in the turf. When it has subsided, the mixture is turned over again, as before, and the turf or peat at the same time broken very small, that it may mix the more intimately with the dung. This often produces another fermentation, more powerful than the flrst. The mixture is mostly ready for use in the beginning of the spring. If lime be used, the quantity is very much less than that of the dung, but the proceeds otherwise much the same.

If, for this purpose, the turf or peat were thrown up in long narrow ridges, and a little quick-line dusted between the different layers, it would, it is suppod by fome, expedite its separation, and disfufe it sooner to incorporate with putrid matters.

This sub stance has likewise been used with great benefit in both of these mixtures, as well as in its simple reduced state in different instances, in Lancashire, by Mr. Paterfon and others. See a paper in the third volume of the Transactions of the Highland Society of Scotland, and lord Meadowbank's Directions.

Turf, in Gardening, the green surface or fward cut from pastures, &c. for the purpose of laying down grafs-grounds; as lawns, plats, bowling-greens, banks of pieces of water in pleasure-greens, &c. It is flayed off with the turfing-iron, in regular lengths of two or three feet, and a foot wide; and being properly laid down clofe and regular in the places intended, it immediately forms an even grafs fward, which quickly strikes root in the ground, in proper growth and verdure. This fort of work may be performed any time in autumn, winter, and spring, in open weather, or occasionally in fummer, in a moif fceon; but the autumn is the best fceon. The belt turf is mostly procured from fine clofe-fed pastures, commons, or downs, &c. where the fward is clofe and even; or that of any grafs-field of similar clofe, firm fward, where the grafs is not rank and coarfe, nor abounding in weeds, or much over-run with the common wild daisy, dandelion, or other similar plants.

In the operation of cutting the turf, a line should be drawn tight lengthways of the grafs-ground, and then the cutting-racer be drawn onto the surface of the fward, clofe to the line, putting it along fo as to cut or fcore the fward in a ftraight cut the length of the line, about an inch and half deep; and having thus raced out one length, the line should be moved a foot width further to race out another length as before, proceeding in the fame manner to a third, and fo on to as many lengths of the line, in foot widths, as may be necessary; then, by the fame means, the fward is to be raced cross-ways in yard dillances, and thus the proper widths and lengths are formed. After the fward has been thus raced out, it should be fayed, or cut up with the turfing-iron, beginning at one fide, cutting evenly longways the whole length of each raced line, about an inch or inch and half thick; a perfon following immediately after to roll them up separately in yard lengths, grafs-fide inwards, as clofe and tight as poifible; having thus cut up one range, proceed with another in the fame manner, and fo continue with the whole. As the turfs are rolled up, they should be piled clofe and regular together, ready for carrying away. When cut by the hundred, as is ofte the cafe where large quantities are required, they are commonly piled up in tens; four below, three next, then two, and one at top, for the more ready reckoning of the number wanted.

In performing this fort of work, it is conftantly neceffary to keep a steady even hand, in order that the turf may be cut all of an even regular thickenes without any fort of lumps or lumps, which renders it fels difficult and troublesome to lay down, as fuch lumps caufe many inequalities that can-
TURF not be easily made level, but require so much heating as often to greatly injure and destroy the turf, as well as to be productive of a great waste of time and labour, thereby causing a great deal of unnecessary expense. Besides, such work under these circumstances can never be done so well as where the contrary is the case.

Turf-After, in Agriculture, those formed from any sort of turfy or peaty matters. Turf-ashes have been used as a manure on poor thin soils, in some districts, with great effect and advantage, and for potatoe crops, but they are probably, in general, the best when employed as top-dressings for grasses and certain kinds of crops. See Top-Dressing.

The ashes formed from turf or peat in Berkshire have lately increased greatly in value, in consequence of their general application as a top-dressing to clovers and other sorts of artificial grasses, as well as to tares, turnips, and occasionally wheat in the young state of its growth. The usual time of applying them is the very early spring. They are there commonly taken in carts, and thrown by the hand over the ground, either before or after the feed for the crop is sown. But when used only as a top-dressing, they are merely thrown on the surface of the land evenly by the hand. The quantity made use of is mostly from twelve to fifteen statute buclhees to the acre, as the soil and crops may be. It is believed, that too large quantities would be hurtful. Some do not hold them in much estimation for grain crops, or those of the pea kind; but they are preferred to all other manures, especially for all sorts of artificial grasses. In turnip crops, they are said to afford much in preventing the ravages of the fly; and in those from the seeds of grass, the farmers suppose, that on an acre which is manured with them, the produce in hay will be nearly a ton more than what it would have afforded without them.

On meadow-land too, in some cases, from fifteen to twenty bushels of these ashes may be laid with great improvement to the grasses. The effect of them is supposed to be not of longer duration than two years. Several acres may be gone over with the scowing of the ashes in the course of a day, by one person and a two-horse cart. See Ashes and Sulphate.

Turf-Drain, a term applied to that sort which is formed in turfy situations, and filled with turves or peats; and which is done in an useful, neat, and successful manner in many districts, especially in Lancashire, as may be seen in the corrected agricultural report of that county. It also signifies a sod-drain. See Surface-Drain.

An improved mode of turf or sod-draining may likewise be met with in the report on agriculture for Cheshire.

Turf-Hedge, that sort of fence which is formed by means of fods, or the dug-up turf, and plants of different kinds. For turf-hedges that are to be fix feet high when finished, six-feet bales are allowed in some places, as in Cornwall; and as they lette a good deal, half the height is only built at a time, with the filling well ridged up in the middle to throw off the wet. This remains to lette perfectly, when the other half is laid, and the proper plants or cuttings put in. This is thought to be an improvement in the forming of this sort of fence. See Fence.

Turf-Hoyle, in Rural Economy, that sort which is formed of the turf cut from land, and which is common in the northern parts of the island.

Turf-Moff, or Bog, a term applied to a tract or extent of turfy, moffy, or boggy land, from which turf is cut, or which stands in need of being reclaimed and brought into order by suitable draining, and the proper application of weighty earthy substancess of different kinds. See Bog, Moors, and Mosses.

Vol. XXXVI.

TURF

Turf-Spade, a tool of this kind, which is used in cutting turf for fuel. It is about four feet in length with the handle, and four inches in breadth, being made sharp in the mouth part, and having a brown iron on one side of it, which is bent or turned up to a right angle, that it serves to cut and separate one side of the turf from the bed of turfy matter, as the back and mouth of the implement do the other.

The work of cutting the turves for burning by means of this spade, is performed somewhat in this manner: the ground being first marked out on the surface in a straight line, of a length at pleasure, and between three and four feet in width, is then dug level on the surface with a common spade, the whole of the bad and imperfect turfy parts being removed. The turf is then cut by a person standing in the pit or ditch, with the narrow spade described above, which is laid at the lower end with iron, as has been laid, in a sharp manner. By this means every turf is cut and formed into a long fort of square, which is then taken from the workman, and spread on the ground in a clothe manner, until dry, when they are set up on end, three or four together, and afterwards put up into windowds and small stacks, till ready to be led or carried home for ufe.

The spade which is made use of in cutting the turf or peat for being reduced into ashes in Berkshire, is somewhat of this form too, but it has a considerably greater length of the mouth-part. The turf or peat, when dug by it, is carried from the spot in little wheel-barrows, to a short distance, where it is spread on the ground, and after lying some days, the pieces are turned, which after being several times repeated, a heap is made of it, in the middle of which dry turf is put, which is set fire to, and the whole slowly burnt, additional quantities of turf or peat being occasionally supplied, so as that the burning may be slow and smothering. The heap is mostly of a circular form, and rather flat at top, being small at first, but ultimately sometimes two or three yards in depth, and fix or seven in diameter.

The remaining materials, when pafled through a riddle, are taken away, in a covered manner, to great distances.

Turf-Sewing, an Indian method of curing diseases, which has been found to succeed very happily on many trials.

Paul Dudley, esq. gives an account of a man of seventy-four years old in New England, who drinking cold water when very hot, had a pain letted in one side and arm, which baffled all art to remove; till after nine weeks confinement to his bed, when he was given over by every body, it was proposed to try this method of cure upon him.

An oven full of turf was ordered to be cut; the turves were of about eighteen inches square each, and were of the nature of the Englih turf used in gardens.

The Indian doctor, before the turf was put into the oven, rubbed over their grassy side with some fort of oil or spirit, and then putting the two grafes sides together, placed them in the oven. When they had been two hours there, and were well baked, he took them out, and made a bed upon the floor, the place for the head being a little raised; the old man was then taken out of bed without his shirt, but wrapped in a sheet, and being laid on the turf-bed, such another parcel of the hot turf was laid over him. The turf was laid thickest on that side where the pain was, but none of it was put on his breast or head.

He was then covered with a blanket to keep in the heat, and while he was in this warm bath, he was continually suppled with warm cordials to keep him from fainting, of which he was in great danger. After he had been in this bath about three quarters of an hour, which was as long as
he could bear it, he was put into a bed very well warmed, without his shirt, where he soon fell asleep, and sweated to that degree, that it ran through the pillow and bed on the floor. After about two hours' sweat, they rubbed and dried him, and put on his clothes, and the old gentleman found himself much eafeed and refreshed. The operation was performed in the morning, and before night he walked about the house comfortably, his pain being almost all gone. The cording were, after this, repeated, and, on the fourth day, the sweating was performed again; the day after which, the old gentleman was well enough to go about his busines. He lived eleven years afterwards in perfect health, and free from pain.

Great care is to be taken in this operation that the patient do not lie too long in the turf: in many cafes, a quarter of an hour is found to be long enough; and the general rule is, that as soon as the patient begins to fetch his breath short or faint, he must be put to bed immediately, and the cordin must by no means be omitted, for the life of the patient is endangered without them. Phil. Tranf. N° 384, p. 129.

TURFAN, in Geography. See Tourfan Hotun.

TURFING, in Gardening, the operation of laying down turf. In preparing the ground for this purpose, it should, where loofe, be well trodden, or occafionally rolled and rammed; then be properly levelled on the surface with the spade, and afterwards raked smooth; when it is ready for laying. In laying the turf, they should be unrolled regularly on the ground, each in its place, making them join close edge to edge, fo as to form at once a close even fward; beating the whole down close and even afterwards with a heavy wooden beater, to fettle the roots of the grafts clofe to the earth, as well as to form the surface equally clofe, firm, even, and smooth; the turf thus foon ftriues root below, and grows above, without any further care in this part of the busines, except occafionally beating down any swelling inequalities, and fometimes rolling it with a heavy iron roller. Sometimes, when turf is laid in the fummer, or in the early part of autumn, in dry hot weather, it will shrink and open considerably at the joinings, and affume a decayed-like appearance. In this cafe, a few good waterings would be ferviceable; but fhould this be omitted, the firft heavy rain will moftly recover the whole effectually, and swell the fward, fo as to clofe all the chafins, and revive the verdure of the grafts plants, when a heavy rolling fhould be given, to fettle the whole firm and even, and to give the surface a neat appearance. The principal fhirmpoft to be regarded in this part of work, is to have the surface of the ground well levellled before the turf are laid down, for where this is neglected, it is utterly imposfible to do the bufines fo as to look well.

In refpeft to the after-culture of ground formed with turf, it is chiefly to give occaftional mowings, from the spring through the fummer till October, and offenfionally poiling and rolling the surface to keep it even and level. The mowings in these cafes fhould confantly be performed before the grafts gets to too high a growth, fo as to injure the surface appearance by rendering it tender and of a bad colour.

TURFING-Iron, an implement made ufe of for flaying or cutting up grafts, turf, or fward from land for the purpofe of turfing: it is formed with an iron plate for the cutter, from fix to leven or eight inches wide, a little rounding forward at the edge, which is thin and sharp for cutting, but thickening gradually behind to the upper part, where it is forged to a long bent iron handle, the bending fo formed as to admit of the plate or cutter refting flat with its back on the ground, in the proper poftion for readily cutting or flaying the turf or fward evenly off, of a regular depth or thicknefs; the handle at top being either formed of iron, with an opening like the top of a fpade, or a focket in which to fix a short wooden handle of that kind. In using it in cutting the turf or fward, the workman takes hold with one hand in the top handle, the other below, with the latter guiding the tool in the proper position, whilst the upper hand is placed against his knee, &c. which affifts him in thrusting it forward into the ground evenly under the fward; and thus he proceeds along in a regular manner, moving the tool gradually along at each froke, level and even, at an equal depth. Thus, as one range of turf or fward is pared off, another is begun with until the whole work is done.

It is neceffary that the edges of the cutting iron fhould be well fpecked, and ground perfectly sharp, as the labour by fuch means is rendered much lefs, and the work far better performed.

TURFING-Spade, in Agriculture, the name of an implement ufed to under-cut the turf, after it is marked out with the plough, in the old practice of paring and burning the turfy surface of land.

TURGA, in Geography, a town of Bengal; 40 miles S. of Dofea. N. lat. 22° 22'. E. long. 85° 5'.

TURGANA, in Ancient Geography, an ifland on the coaft of Arabia Felix, in which was a very magnificent temple dedicated to Serapis, according to Ammianus Marcellinus.

TURGESCENCE, TURGESCENCY, a swelling or growing bloatet.

TURGHE, in Geography, a river of Wales, which runs into the Cothey, in Caermarthenhire.

TURGOT, ANNE-ROBERT JACQUES, in Biography, an enlightened and patriotic minifter of flate, was born at Paris in the year 1727, and studied theology at the Sorbonne, where, in his 22d year, he delivered two Latin difcourles, "On the Advantages derived to Mannkind from the Christian Religion," and "On the Progrefs of the Human Understanding." At the age of 24 he tranflated Virgil's Georgics, and thus a change took place with regard to the direction of his studies; fo that he became attached to the principles of Quefuy, and of the fect called Economists. Having quitted the Sorbonne, he was appointed intendant of Limoges; and in the course of twelve years, during which he occupied this office, he conduct in distributing alms and providing a supply of food in a time of fecrivity, and in introducing various improvements in the province, esta blihed his character, and commanded for him great refpeft. With him, it is faid, firft originatet the institution of charitable work-shops. As comptroller-general of the finances, he adopted various regulations, which, without injuring the revenue, encouraged industry, promoted agriculture and commerce, and lightened the burdens of the lower classes. Although many of his beneficial plans of reform were treated with contempt and ridicule, he succeeded to a confiderable degree in ameliorating the flate of the country. His re solution, diligence, and activity, overcame many obfacles and difficulties, in fomuch that the benevolently difpofed Lewis once faid, on leaving the council-chamber, "No one loves the people but M. Turgot and I;" nevertheless, the cabals againft him prevailed, and he was difmissed from the important office which he occupied with fo much advantage to the people. As an incitation to his industry, he alleged, that in his family life was not protracted beyond the age of 50; and therefore, having but a few years before him, he determined to leave nothing unfinished. Accordingly he died in 1781, at the age of 49. Of the pieces which
which he published, Condorcet has given an account in a "Memoir on his Life and Writings," 1782, 8vo. La Harpe has given us the following sketch of his character. "He was a man of a strong mind, whom nothing could divert from justice, even at court, and in the highest places; of an unalterable equanimity, even in the midst of the oppositions and disfrufs of his ministry; of a laborious activity, which device could not flacken. He had only two passions, that of science, and that of the public good. During the few years in which he occupied the post of minister of finance, he bent all his views to the relief of the people. Attaching to the doctrines of the Economists, he developed them in edicts which tended to the encouragement and improvement of agriculture. He was the first among us who changed acts of the sovereign authority into works of reasoning and perfusion; and it is perhaps a question whether this method may be useful or dangerous. His suppressions and reforms in the finance raised him many enemies; but among all who complained against him and reproached him, not one attacked his integrity. No one disputed the purity of his motives, but fault was found with his measures. Perhaps there was something unyielding in his character, which impeded the good which he wished to effect. Further, the courtiers could not pardon a minister who encircled himself with men of letters and philosophers." His innovation in favour of the people created a prejudice against him, on the ground of his being one of the promoters of the French revolution. Nouv. Dict. Hist. Gen. Biog.

TURGHUT, in Geography. See DURGUT.

TURHUSSY, a town of Bengal; 17 miles N.N.E. of Palamow.

TURIA, in Botany, an Arabic name, retained by Forskal, Fl. Aegipt.-Arab. 165, and cited by Jussieu, Gen. 395, under Anguria. The above name, if wanted, might not be inadmissible; at least, if any fuch, of barbarous origin, are allowed to remain. But whether the five, partly doubtful, species on which Forskal has founded his genus be really entitled to stand alone, or whether they may be referrible, as Jussieu hints, to Anguria, or to any other genus of the Cucumber tribe, no one, conversant with Forskal's works, will, fully, venture to determine. He attributes a pendentulous corolla to these plants, which is an unexampled in their natural order, and which, by other parts of his account, appears to be an error. The villous cylindrical fruit, tapering at each end, and marked with ten furrows, will scarcely afford a generic character.—Forskal's first species, Turia of the Arabs, to which he has given no specific name, is cultivated in Yemen, but we are not told for what purpose. Some of the others are called, in that country, Leola or Lua, Giff, and Moghad.

TURIAMO, Bay of, in Geography, a bay of Caraccas, three leagues to the windward of Porto Cabello, which extends one league from north to south. Having no shelter from the north wind, and the country round it affording no commodities sufficient for inducing merchants to encounter its inconveniences, fearfully any ships resort to it. The cape is the same with regard to Pataneu, Borburata, and Sianega. The whole population of these bays confines of no more than a small party of soldiers, flattered there to prevent smuggling.

TURIANO, a river of Sicily, which runs into the sea, 10 miles N.E. of Milletta.

TURIAS, the Guadalquivir, in Ancient Geography, a river of Hither Spain, on the banks of which was built the town of Valentina.—Alfo, a river or torrent of Italy, mentioned by Silius Italicus (l. xiii. v. 51), and thought to be the fame with that mentioned by Livy, and placed six miles from Rome. But the orthography is much controverted.

TURIASO, TARAONA, or TARAZONA, a town of the interior of Hither Spain, towards the south-west. Pliny speaks with high commendation of its iron. It was municipal. It was situate east of Numantium, and south-west of Calaguris.

TURICUM. See ZURICH.

TURIGA, a town of Spain, in Bética.

TURIGA, in Geography, a river of Ruftia, which runs into the Niznei Tagutula, N. lat. 66° 12'. E. long. 98° 44'.

TURIN, a city of France, capital of the department of the Po, during the revolution, before and finance capital of Piedmont, situated at the conflux of the Po and the Grand Doria, about seven miles from the foot of the Cottan Alps, in the road from France to Italy, by the way of Mount Cenis. According to Pliny, the inhabitants derive their origin from the Ligurians, and were anciently called "Taurni." Hannibal, the Carthaginian general, when he invaded Italy, took and destroyed the town, because the inhabitants would not take part with him; which frightened the other people who inhabited the banks of the Po. It was erected into a Roman colony by Julius Caesar, who gave to it the name of "Julia," and it was called "Augusta Turinorum" by his successor Augustus. It was successively subjected to the Goths, Huns, Eruli, and Burgundians, who ruined and destroyed it; but it was soon rebuilt, though not so large as before. When the Lombards became masters of the country, it became the capital of one of their principal duchies. Some of the dukes became kings of Italy. After Charlemagne had abolished the kingdom of the Lombards, Turin became subject to the marquis of Sufa, who had the charge of guarding the paffages of the Alps, and continued in that family to the death of Ulric Manfred, the last marquis of Sufa, in 1302; whose daughter, Adelaide, married Odo, comte of Maurienne and Savoy. Turin submitted to him and to his descendants, who fine poifefled it with little interruption till its union with France; before which Turin was the fee of an archbishop, and was paid to contain 110 churches or chapels, three hospitals, and about 80,000 inhabitants. The approach to it is magnificent, and the environs beautiful, though thick fogs from the two rivers are frequent in autumn and winter; so that the air of Turin is then very thick and moist. The four gates are highly ornamental; the streets in the New Town are wide, straight, clean, having plenty of water running through them, well built, in a good taste, chiefly of brick ituccoed, and generally terminating in some agreeable object. No inhabitant could rebuild or repair his house but on an uniform plan, laid down by government, for the improvement of the city. The fortifications of Turin were regular, and kept in excellent repair. The citadel is a regular pentagon, confifting of five strong bastions, and is reputed one of the strongest in Europe. At the end next the new gate is the arsenal, which, besides the armories found in such places, contains a cabinet of minerals, a good chemical laboratory, a library of books in mineralogy and metallurgy, and furnaces for casting cannon: here, also, are mathematical, mechanical, and other matters, for the instruction of engineers, miners, &c. The garrison of Turin was changed at the end of two years, and then there was a general review. The university was founded first in 1405, by Aramdeo, duke of Savoy, and consists of schools, wherein 24 professors read lectures, from the 3d of November to the 24th of June; the royal library, in which are about 50,000 volumes of printed books, besides manuscripts, is open every day, 11 2;
day, except holidays, both morning and afternoon. The royal museum has a good cabinet of medals, and a collection of antiquities, found chiefly in Piedmont or Sardinia, and elegantly arranged: also of natural history, as shells, and English minerals, polished marbles, and hard stones, petrifactions, corals, zoophytes, and some minerals, collected by Donati in the Adriatic; also, some shells of natural curiosities, which Donati during his travels in Egypt and Arabia, sent from Goa. In the military academy, young gentlemen, both natives and strangers, might be instructed in the exercises at a moderate expense, the king defraying a part of the charge attending this institution. The palace is in a simple and noble style of architecture. The apartments are handomely fitted up and furnished; the ceilings painted by Daniele di Sandterre and others. The town-house contained a great collection of pictures, among which were many good ones. The king's theatre, a great opera-house, is reckoned one of the finest in Europe. The buildings which are most esteemed in point of architecture, are the palace of the duke of Savoy, called Castello Reale, by Filippo Guvara; the Carigranno palace, by Guarini; the buildings of the university, and the town-house. There is a literary society at Turin, which has published memoirs, under the title of Miscellanea Philosophico-Mathematica. The chief trade of this city and country is in thrown silk, which is sent to England and Lyons; they manufacture, however, some of it into excellent frockings, and good silk for furniture. In the year 1536, Turin was taken by the French, and again in the year 1640, after a long siege. In the year 1766, the French enemy made another attempt; but after besieging it upwards of three months, under the conduct of the duke of Orleans, they were driven away with great loss, by the duke of Savoy and prince Eugene. In December 1797, the French took this city, and levied on the king of Sardinia a contribution of 2,000,000 livres. In May 1799, it was taken by the Austrians and Russians, and the citadel surrendered soon after. It was afterwards surrendered, with the whole of the principality of Piedmont, to the French republic, but restored after the revolution and re-establishment of the French government. N. lat. 45° 3'.

At Turin, accounts are kept in lire, soldi, and denari; Piemontese currency: 12 denari = 1 soldo, and 20 soldi = 1 lira: accounts are also kept in francs and centimes, as in France. The gold coins now in circulation are carlini, of 5 doppie or piccoli, with half carlini in proportion, and doppie, with halves and quarters in proportion: the carlini pass for 120 lire, and the doppia for 24 lire; Piemontese currency. The silver coins are reals of 6 lire, with halves, quarters, and eighths in proportion. Here are also base silver coins of 34 and 23 soldi; and copper coins of 1 soldo; also pieces of 3 denari, called quattrini. The doppia contains 1721 Troy grains of fine gold, or 1991 grains of English standard gold, and is worth 15. 21. 6 d. in English gold coin: the ledu contains 492 Troy grains of fine silver, or 532 of English standard, and is worth 51. 8 d. in sterling silver coin: thus the lira Piemontese currency may be valued at 111. 4. 0 d. Sterling. The rubbo, commercial weight, is 25 lbs., each pound containing 14 mark, or 12 oz. of the gold and silver weight: so that 70 lbs. of Turin = 59 lbs. avoirdupois. The facco, corn measure, contains 3 lega, 6 mine, or 48 cappelli; and 22 facchi = 9 English quarters nearly: the brenna, wine measure, contains 6 rubbi, or 36 pinte; the rubbo weighs 25 lbs. of Turin, and holds about 2½ English gallons. Oil is sold by the rubbo of the same weight, or 20½ lbs. avoirdupois: the rolo or ell is = 2½ English palmi = 23¾ English inches; the foot = 143.2 French lines = 34½ English inches; so that 180 Piemontese rali = 119 English yards, and 33 Piemontese feet = 35 English feet.

Turin exchanges with, and gives Amflerdam, 38 soldi, more or less, for 1 florin banco; Augsburg, 46 soldi for 1 florin current; Geneva, 86 soldi for 1 eeu of 3 livres current; Genoa, 190 soldi for 1 sequin; Leghorn, 82 soldi for 1 pezza of 8 reali; London, 409 soldi for 1 sterling; Lyons and Paris, 50 soldi for 3 livres Tournois; Milan, 98 soldi for 1 filippo of 7½ lire current; Rome, 90 soldi for 1 fucido of 10 paoli; Venice, 54 soldi for 1 ducat piccoli.

The usance for bills drawn from London is three months after date, from Holland two months, and from France one month. The holder of a bill payable after date, may either demand payment when it becomes due, or wait till the fifth day; but bills at sight must be paid when presented. Kelly.

TURIN, a large post-township of New York, in the S.W. corner of Lewis county, 143 miles N.W. of Albany. It comprises seven townships, viz. Pomona and Lucretia, adjoining Black river, and on which are the Settlements; Flora, Xenophon, Ruckelbly, Hybla, and Penelope, unsettled. The settled part is about nine miles along Black river and seven back. The inhabitants are emigrants from the eastern states, farmers of plain domestic habits. Here are nine school-houses, in which are also held the meetings for worship. The whole population in 1810 was 856, and the senatorial electors were 111; in 1812, 170. The Black river road from Johnstown leads through this settlement, which has an excellent soil, and in which are two grain-mills, six saw-mills, a carding machine, and two distilleries of grain and fruit spirits.

TURING, a town of Sweden, in the province of Blekingen; 7 miles N. of Carlcorna.

TURIN, a town of Sweden, in Sudermanland; 24 miles W.S.W. of Stockholm.

TURINI, Francesco, in Biography, an eminent Italian composer of the seventeenth century, who gained great reputation by the composition of canons. He was organist of the Duomo at Brescia, and published many learned compositions for the church and chamber; but particularly a mass in 1643, for four voices, in canon.

In this work there is a perpetual fugue, upon the subject of which Handel has composed one of his finest instrumental fugues; but, according to his usual practice, whenever he adopted another's thought, he has enlivened and embellished Turini's theme, like a man of true genius, with a counter-subject; and shewn that he saw farther into the latent fertility of the fame series of notes, than the original inventor, whose theme was the following:

\[ \text{\textbf{Turin}} \]

The first sonatas for two violins and a bafe, which our musical enquiries have been able to discover, were published by Turini, with a let of "Madrigali a una, due, tre Voci, con alcune Sonate à due et à tre," Venezia, 1624. We were intrigued by this early date to score one of these sonatas, which consisted of only a single movement, in fugue and imitation throughout; in which so little was made of the power of the bow in varying the expression of the main theme, at each part might have been as well played on one instrument as another.

The violin does not appear to have been Turini's instrument. A canonic need have nothing else to think of, than
the solution of harmonical problems, which require such intense application as to leave him not a single idea to dwell on any thing else.

TURINSK, in Geography, a town of Ruffia, in the government of Tobolisk, containing a wooden fort, seven churches, and about 350 houses; 144 miles W. of Tobolisk. N. lat. 58° 25', E. long. 63° 44'.

TURINSKOI, a town of Ruffia, in the government of Tobolisk, on the Niznei Tungufka; 132 miles E. of Turuchank.

TURIONS, in Botany, the first young tender shoots which plants annually put forth.

TURIRANA, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 1° 30'. W. long. 4° 46'.

TURISSA, in Ancient Geography, a town of Spain, at the foot of the Pyrenees, in the country of the Vafconi, N.E. of Pampela.

TURK, in Geography, an appellation of very ancient origin and of very comprehensive extent. It is said to be derived from the name of one of the sons of Japhet, the eldest son of Noah, who is generally allowed to be the progenitor of the Moguls and Tartars. This opinion has been adopted by those who have been most conversant with Oriental literature, and the Tartars themselves have expressed their persuasion of its truth. Accordingly it is said, that the progeny of Magog, Meshech, and Tubal, subverted both the Scythians, and consequently the country of the ancient Moguls and Tartars. If it be admitted that the Turks and Tartars were originally the same people, whatever is advanced concerning the first progenitors and early antiquities of the one, must, with the slightest propriety, be applicable to those of the other.

It has been alleged as highly probable, that both the present Turks and Tartars are descended from the Scythians of Ariless Proconneus, and the Scythian Nomades of Herodotus (lib. iv.) Upon this supposition, the ancient Turks or Tartars cannot be considered as one of the earliest nations of antiquity, nor as occupying a tract for many ages of very considerable extent. For they scarcely made any figure at all before the reign of Cyaxares, king of the Medes, or the time of Ogres Khan, about 637 years B.C. when they drove the Cimmerians from their territories bordering upon the Palus Moetis into the Upper Asia. Nor could their primitive seat, upon the eastern bank of the Volga or Araxes, have been at that time very extensive; since it is well known that they were then a people of little note, and in the vicinity of some nations who were contending for unlimited empire. In the time of Herodotus, Scythia lay only between the 45th and 57th degrees of longitude, and the 47th and 53d degrees of N. latitude, so that the Scythians at that period cannot be regarded as a very formidable power. The first Scythian king, according to this historian, did not live above 1000 years before Darius Hytafaspe invaded Scythia, in the year B.C. 514; or by reducing the calculation of the Greeks and other ancient nations, as for Isaac Newton has done, it may reasonably be supposed that the first Scythian prince could not have preceded Darius Hytafaspe above 800 years. At this early period, therefore, or 1300 years before the commencement of the Chriftian era, the countries bordering upon the Palus Moetis, as well as the Euxine and Caffian Seas, must have been very thinly peopled. The Tartars, however, though they derive their name from Tatar Khan, pretend that this was not their primitive appellation, but that they are the descendants of Turk, as we have already said, the eldest son of Japhet, whom they call Japhis; and accordingly maintain that they were originally denominated Turks; which name they seem to have retained till the time of Genghis Khan. But when that prince reduced all the tribes bearing the name of Turks under his obedience, they, with regard to their neighbours, gradually lost it, and were by them afterwards called Tatars. Nevertheless, though this was the case with respect to their neighbours, most of them have always denominated themselves Turks; nor do they allow, that any other nation has the least title to that denomination. The name of Tatars was at first probably applied to one particular tribe or horde of the Tartish nation, confining of persons more considerable, warlike, and better known to the Aftatics, on account of their military exploits than the rest, till the time of Genghis Khan. This was succeeded by that of Moguls, which prevailed as long as the dominion of the people so called lasted over the southern provinces of Asia; when that expired, the former appellation was resumed. It is observable, that Sherif al Edrith, commonly called the Nubian geographer, makes no mention either of Moguls or Tatars; but intimates that the whole country bearing now the denomination of Eastern and Western Tartary, was peopled by different cantons of Turks. This is the more remarkable, as that author wrote but a little before the reign of Genghis Khan, about the year of Chrith 1170.

Turk, it is said, was appointed by his father Japhet to bear the chief rule in his family after his death; and being a man of superior genius, he invented many of the conveniences of life, made tents, and governed his family and subjects with great justice, prudence, and moderation. He also formed a body of falutary laws for his descendants. Turk is said by the Tartars to have had four sons; and from him the country in which he settled was called Turkeftan, and his subjects were denominated Turks. From Tatar Khan, the Tatars or Tartars derived their name, as the Moguls did their's from Mogul or Mung' Khan. These two branches of Turks, being rendered independent of one another, formed two considerable empires, which flourished for several generations. See Mongoles and Tartars.

The name Turk, says Volney, originally, was not peculiar to the nation to which it is now applied; it denoted, in general, all the hordes dispersed to the east and even to the north of the Caffian Sea, as far as beyond lake Aral, over those vast countries which have taken from them the denomination of Turkeftan. These are the same people, who were known to the ancient Greeks by the names of Parthiaus, Mafafetcs, and even of Scythians, for which we have substitued that of Tartars. These formed a nation of shepherds, continually wandering like the Bedouin Arabs; and in every age exhibiting themselves as brave and formidable warriors. Neither Cyrus nor Alexander was able to subdue them. The Arabs, however, about 83 years after Mahomet, by order of the caliph Waled I. invaded the country of the Turks, subdued them, and imposed upon them their religion; and obliged them to pay tribute. But the power of the caliphs was refited and vanquished. Like the Bedouins, the Turks were divided into tribes or camps, called "ordou," of which has been formed the term borde; and these tribes, allied or at variance, according to their several interests, were perpetually engaged in wars. Hence we fee, in their history, several nations, all equally called Turks, alternately attacking, destroying, and expelling each other. Volney, in order to avoid this confusion, has confined the name of Turks to those of Constantinople, and given that of Turkomans to their predecessors. (See Turkomans.) For a further account of the Turks, see Turkeftan and Turkey.
TUR

TURK’S-CAP, in Botany, a name given to a species of lily. See LILIUM.

TURK’S-HEAD, a name sometimes given to the melon thistle.

TURK’S TURBAN, a name given to a species of ranunculus.

TURK ISLANDS, or TURK’S ISLANDS, in Geography, a cluster of small islands among the Bahamas, the largest situated N. lat. 21° 20’. W. long. 71°.

TURKAL, a town of Asiatic Turkey, in the province of Sivas; 25 miles S.E. of Amaref.

TURKAREL, a town of Candahar; 30 miles W. of Cabul.

TURKEIM. See TURKHEIM.

TURKESTAN. See TARAZ.

TURKESTAN, (formed of TURK and efian, a Persian word signifying country,) or Turan, a country of Asia, bounded on the N. by deserts, which separate it from the dominions of Russia, on the E. by a part of Tartary, belonging to the Kalmucks, on the S. by Bucharia, and on the W. by Charafm or Karafm, near 300 miles in length, and not much less in breadth. It is at present divided between two Tartar khans or chiefs; one of them, residing at Taftkund, possesses the eastern part; the other, who possesses the western part, resides at Turkeftan or Taraz. The latter is generally called the khan of the Karakalpah. Turkoftan, taken in a larger sense, is understood to include all the country between Russia to the N. and Bucharia to the S., and between the Caffian sea to the W. and Chinese Tartary on the E., not less than 700 miles from E. to W. and 350 from N. to S.

In ancient periods, Western Turkeftan and the N. of the Caffian were the seats of the Mallafetæ; to the S. of whom were the Scythians, on this side of the Ilmaus or Belur-Tag. In the fifth century, the Turks, having migrated from their habitations near the mountains of Bogdo, adjoining to those of Altai, or the mountains of gold, and having impaled to the country the name of Turkeftan, and forming a grand branch of the Tartars, or Huns, spread themselves to the Caffian. They soon after subdued the people of Sogdiana, and the Nephthalites of great Bucharia, called in that ignorant age White Huns. As the Turks founded their first western settlements in the regions now held by the Kirgus, they thence received the name of Turkeftan, the capital city being denominated Otrar, and sometimes Taraz, also called Turkeftan. From the centre of their power issued those Turkifh armies, which have changed the destinies of fo many nations. Little Bucharia was called Eastern Turkeftan from a similar cause; but appears to have been first subdued by the Turks of Cathay, on the N.W. of China. The Turks and Huns may be considered as one and the same Tartar race, totally unknown to Europeans till the appearance of the latter, who first passed the steppes, deserts and mountains which had concealed them from observation till the fourth century. The Huns, who appeared about A.D. 375, feemed to the writers of the period as a new and unknown race, having passed in a course of uniform depredation from Asia to Europe; while the Gothic and Slavonic nations had left many of their settlements vacant, in their progres into the Roman empire. But the Turks, though originally the same people, perhaps warned by the fate of their brethren, made a slow and gradual progres, and appear to have been blended by marriages and conquests with the Slavonic and Gothic tribes on the N. and E. of the Caffian. Such was the origin of the name of Turkeftan, from which the Turks spread defolation over the most beautiful countries of the Eait, and even threatened the liberties of Europe. Pinkerton’s Geog. vol. ii. See BUCHARIA and INDEPENDENT TARTARY.

TURKEY, an extensive empire, comprehending a great number of countries on the continents of Europe, Asia, and Africa, and several adjacent islands.

Turkey in Europe extends, according to the statement of Pinkerton, about 870 miles in length, from the northern boundary of Moldavia to Cape Matapan in the Moree; and its breadth, from the river Unna to Confiantinople, is about 680 Britifh miles. It is computed to contain 182,560 square miles. Its eastern and southern boundaries are formed by the Euxine or Black sea, the sea of Marmora, the Archipelago, and the Mediterranean. Its utmost northern limit is now the river Danifer, and the western confints of an arbitrary line, sometimes supplied by rivers or mountains. In its whole extent it comprehends many ancient kingdoms and republics, which, since the subjugation of its greater part in the 15th century, after the fall of Confiantinople and of the Byzantine empire, afford only the records of classical names and events. Moldavia, the moft northern province, was part of ancient Dacia; and Jaffy or Yaffy, the capital, was the “Jaffiorum Municipium” of the Romans. Budzec, or Beflarabia, was the country of the Hetæ and Peucini. Walachia was also a province of the ancient Dacians; and Bulgaria, on the S. of the Danube, embraces nearly the two provinces of Media. Romelia, a fparicious territory, contains ancient Thracia, Pannonia, Macedonia, and the northern part of the confitical country of Greece; and the Morea is equivalent with the ancient Peloponnesus. Dalmatia retains its ancient appellation; while Servia and Bofnia represent ancient Pannonia. Turkifh Croatia, the moft western province of the empire, forms a portion of ancient Pannonia, with probably a small district of Noricum; but the Turkifh part of Croatia is a diminutive province, about 40 miles in length by 20 in breadth, bounded by the river Save on the N., and partly by the river Unna on the W. In modern times Turkey, linking before the power of Russia, has loft the provinces of the Crim and New Servia, which, with several Asiatic districts, have surrendered to Russia; and on the W., Tranfylvania, Slavonia, with the Buckovin and part of Moldavia, and a great part of Croatia, have been fubjugated by Austria. Of the original population of the Turkifh empire, we have already given some account under the article TURK; and it appears to have been derived from the ancient Scythians on the Euxine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. These were originally blended northward with many Sarmatic or Slavonic tribes; which on the fall of the Roman empire migrated towards the S., so that about one-half of the population may now be regarded as Slavonic. Walachia, however, is fupposed to contain many descendants of the ancient Roman settlers in Dacia. This original population, in conquence of the extent of the Turkifh empire, has been blended with various Asiatic tribes, among whom the Turks constitute a part. Of that branch called Ottomans, and the commencement of the appellation of Ottoman empire, we have already given a brief account under the articles OTTHMAN and OTTOMAN; and for the more remote antiquity of the name and power of the Turks, we refer to TURK. Those Turks, or Turkomans, defending, about the middle of the sixth century, from the Altaian mountains, spread as far as the lake Massotis; but their progres was refticted to the region near the river Oxus: from the Oxus and Samarcand they afterwards spread to the E. of Perfia, where Mahmoud of Gazza eftablifhed a powerful king- dom, subdued by the Turks of Bochara, who in the 11th century
The Turks, and the decline of the Ottoman empire. We may here observe in general, that the Turkish dominion, wherever it has prevailed, has been detrimental in a very high degree to the best interests of humanity, and to every improvement, mental or moral, ecclesiastical or civil.

The religion of the Turks is the Mahometan; although in this European division of the empire, it is supposed that two-thirds of the inhabitants are Greek Christians. The Turkish sultan has for some centuries been the principal leader and supporter of that attachment to the religion of the Koran, which has been the zeyt and guard of the Mahometan faith. The Mahometan pontiff, or mufti, preaches at Constantinople. The next in rank to him are the muftabs, and from these are selected the inferior muftabs, or judges, through the empire, and the candle-fellers or chief justices. The next class of divines consists of the imams or parish priests, who perform the service of the mosques, or places of worship, while the califs are judges annually appointed to administer justice in the towns and villages.

The Turks have also their monks, denominated derviches, of four orders, dedicated to religious offices, public prayer and preaching. Of these, the Kadri constitute a singular order, appearing almost naked, and displaying their devotion by frantic and extravagant dances. The Greeks retain their priests, bishops, archbishops, and patriarchs; but their church is in the lowest state of degradation, and its dignities are openly sold by the Turks.

As to the government of Turkey, the sultan is a despotic sovereign, but so reformed by the laws of the Koran, to which he is bound to submit, that many Christian sovereigns are reckoned more arbitrary. The despotism of the monarch is balanced by a religious aristocracy; and many circumstances have lately occurred, such as the insurrections of the Janizaries, and the power usurped by the pashas over their own provinces, which indicate the decline and approaching perdition of the empire. The Turkish laws are contained in the Koran, and in the comments of approved and renowned doctors, which have acquired the force of laws. The Turkish empire is chiefly guided by those of Abou-Hanife.

The number of inhabitants in Turkey in Europe has been estimated at 8,000,000, or about 43 to each square mile; but as the countries which it comprehends are intersected by many mountains and barren tracts, this estimate is supposed to exceed the truth. The navy is stated at about 30 ships of the line, and the army at 150,000 of ill-disciplined soldiers. The revenues of the whole Turkish empire are computed at about 7,000,000l. sterling, and the usual expense as not exceeding 5,000,000l. Their revenue is partly derived from a capitation tax on unbelievers, and from the “zeechat,” or cuftoms, but principally from a tax on land of about 6s. an acre, called the “jizie.” Upon the whole, the Turkish empire may be regarded as in a declining state, notwithstanding all its endeavours to secure the friendship of various European powers.

Of the manners and cuftoms of the Turks, our limits will not admit of a minute detail. Marriage is a civil contract, managed by female mediation, and liable to dissolution at the pleasure of either party. Circumcision is performed at the age of 12 or 14. The dead are perfurred with incense, and buried in a kind of shroud, open at both ends, that the deceased may be able to fit up and reply to the interrogatories of the angels of death. The burial grounds are near the highways, and as one grave does not intrude upon another, they are very extensive. With regard to diet the Turks are moderate, and their favourite food is rice, of which they prepare their pilaw, boiling it with
with mutton or fowl, their lappa, which is merely boiled rice, and the techorbe, a kind of broth made of the tame vegetable. The fish of the Archipelago is very good, and the beef tolerable; the hares, partridges, and other game are excellent. The meat is usually spread on a low wooden table, over which the master of the house pronounces a short prayer. The frugal repast is followed by fruits and cold water, and these are succeeded by hot coffee and pipes with tobacco. The houses are expensive, and the most costly part of the furniture is the carpet that covers the floor. Their dresses consists of a calico shirt, and the loofe robe is fastened by a girdle, in which is flucked a dagger; while the tobacco-box, pocket-book, &c. are worn in the bosom. The robe is commonly made of English broad cloth, trimmed with furs. The shoes are light flippers. The drefs of the women refembles that of the men, differing only in that of the head, which is a fort of bonnet, formed of paleboard covered with cloth of gold, or other elegant materials, with a veil reaching to the eye-brows, and a fine handkerchief concealing the lower part of the face. In their persons the Turks are very elegantly clad; the females, however, flain their nails with a red tincture. Their amusements are principally such as favour indolence, hunting and military exercises excepted. They are fond of reclining on an elegant carpet, or in a hot fean by the side of a stream, and smoking the delicate tobacco of Syria. With opium they procure what they call "rief," or a placid intoxication, but a stronger dose produces irritation and fercity. Chefs and draughts are favourite games; whereas those of chance are regarded as immoral. Their coffee-houses and baths afford other means of amusement; and the beiram, or festival succeeding their long lent, is a feaon of universal dippation.

The Turkish language is far inferior to the Persian or Arabic, and is formed by a mixture of several dialects. Literature is not wholly neglected, but they have some schools and libraries. In the 18th century a printing-office was fett up at Conflantinople by Ibrahim Effendi, which was at firt much oppofed, but afterwards allowed to print all kinds of books, thoee on religion excepted. The fcriptl fcrif books contains many thofe well fupplied with Oriental MS. texts, and they have their ancient poets, historians, and divines, though of little eftimation compared with thofe of Persia or Arabia. Education, however, is little encouraged: fo that ignorance forms the diftinguifhing character of the nation. Law, connected with their theology, is the chief subjeet of their fudy; but they have no institution that merits the appellation of a college or univerfity.

The chief city of European Turkey, and of the whole Turkish empire, is Conflantinople; next to this in dignity and extent is Adrianople, two miles in circuit, and poffeffing several splendid works, and a confiderable share of commerce; Philippopolis is a city of confiderable importance; Sofia, though meably built, contains about 70,000 inhabitants, and his manageable trade; Siliftria in Bulgaria, on the Danube, contains about 60,000 fouls; and Buchareft, the chief city of Wallachia, is famed to have the fame number; while thoee of Jaffy or Jaffy, the chief town of Moldavia, and Bender of Baffarabia, are each eftimated only at 10,000 or 14,000. Belgrade, the capital of Servia, is fuppofed to contain about 25,000 inhabitans; and thoee of Banjaluka, which is a confiderable town in Bofnia, are eftimated at 18,000. In the fouthern provinces we may firft mention Salonika, containing 60,000 inhabitants, and diftinguifhed by a confiderable commerce; Larifia, 80 Britifh miles to the S., an inland town, containing 25,000 fouls; and Atini, the ancient Athens, of small population. See each article.

If we except the fegaios and royal palaces, the chief edifices in Turkey are the moqubes and caravaners.

The manufactures and commerce of Turkey in Europe are chiefly conducted by foreigners. The Levant trade is almosf entirely centred in Smyrna and the Afiatic shore. The manufactures principally exported from European Turkey are inconfiderable, being chiefly carpets and some few other articles; but the products are currants, figs, faffron, flatuary marble from Pafos, filk, and drugs.

The climate and feasons vary with the different regions comprehended within the limits of European Turkey; and to these we refer for an account of them. The general appearance of Turkey in Europe is mountainous, here and there interperfed with delicious plains and vales; enfranchised by the Danube, which intersects its provinces, and the numerous gulfes of the Archipelago and Mediterranean. The soil is generally fertile, the northern parts producing wheat and rich palture, the middle and fouthern abundance of rice; but agriculture, as well as almoft every other art and science, is neglected by the Turks. The principal rivers of Turkey are the Danube, already mentioned, the Ma-

ritiz or ancient Hebrus, the Vardari or ancient Axius, the Elker or ancient Oelkus, the Morava or ancient Margus, and the Drin, rising N. of Albania, and falling into the Save. Budzag and Walachia, as well as Albania and the fouthern provinces, contain confiderabie lakes. The chains of mountains in Turkey are numerous and extenfive. Here we might mention, if they were not elsewhere noticed, the Carpathian chain, anciently called the Baftanic Alps; the grand range of the Hamus with its branches; and mount Athos of ancient celebrity. European Turkey also abounds with fcrifts. Of its zoology we shall merely notice the jackal, the camel, and hofe, and also its cattle and fheep, which are numerous and of different kinds. Its mineralogy has been little infeigated. The gold mines of Philippick, about eighty miles E. of Salonica, produced in the time of Philip of Macedon annuall about 1000 talents, or 2880,000. sterling; and timber mines were fett in Attica, and other quarters.

The chief ijlands belonging to Turkey in Europe are those of the Archipelago; for an account of thefe we refer to their names, such are Crete or Candia, Negropont, the Cyclades, Sporades, Lemnos, &c. &c.

Turkey in Asia extends from the shores of the fegian sea or Archipelago, to the confines of Persia, through a space of about 1050 Britifh miles. The boundaries towards Peria are the mountains of Arrat and Elwed. Towards the N. the Turkish territories are divided from the Russian by the river Cuban and the chain of Caucafsus; in the S. they extend to the junction of the Tigris and the Euphrates, which laft river separates, for a confiderable in-

terval, the Turkish poftifions from thoee of the Arabs. The diftance from the Cuban to the junction of the Tigris and Euphrates may be eftimated at about 1100 Britifh miles. This extensive empire is divided into nine or ten provinces, viz. Natolia W., Karanam S., and Roum N.E. of Armenia are Guria or Guriel, Mingrelia, and the Akbas of Caucafsus, the ancient Cirafias. To the S. of Armenia, also denominated Turcomania, are Cerdilan or Irak-Arab, part of ancient Perfa, round the celebrated capital Bagdad. The ancient Mafopotamia, between the Tigris and the Euphrates, now partly corresponds with the province of Algeria; and Syria, or Soria, comprehends the celebrated countries along the eafther extremities of the Mediterranean. These provinces are subdivided into governments, arbitrarily administered by pashas. The original population of these regions confited chiefly of Sceytians blended
blended with some few Assyrians from the south. See 
**Turk**, and **Turkey in Europe**, supra.

The prevalent language is the Turkish, to which we 
may add the modern Greek, together with the Arabic, 
Syrian, Persian, and Armenian, with the various dialects 
used by the tribes on the Black sea, and indicating the 
diversity of population. To the account already given of 
the historical epochs of Turkey, we may here subjoin the 
following from Pinkerton. Armenia and Georgia were 
subdued by the Turks in the eleventh century, and the 
whole of Asia Minor soon followed. Their subsequent 
Roum extended from the Euphrates to Constan tinopole, 
and from the Black sea to the confines of Syria. Successive 
warlike princes acquired additional territory from the Mame 
lukes of Egypt and the Persians. Syria, formerly an 
appendage of Egypt, was conquered by Selim II. in 1516; 
Taurus and Diarbekir, the last of which had formerly 
belonged to Peria, were subjugated by the same monarch; 
and in 1580 Abbas, the great sovereign of Peria, was 
obliged to yield three provinces to the Ottomans, though 
he extended his conquests to the ealt; and Bagdad, with 
the surrounding province of Irak-Arabi, became subject to 
the Turks in 1638. The present limits seem to have been fixed 
by the treaty between the Porte and Peria in 1736, since 
which period the Turks have been chiefly employed in 
defending themselves against the Russians; but such had been 
their ascendency over Peria, that in 1727 they had acquired 
the territory from Erivan to Tauris or Tebriz, and thence 
to Hamadan, a boundary which seems to be more precisely 
marked by nature than by the pencil. The antiquities of Asiatic Turkey are those of Balcoc and Palmyra or Tadmur in the desert, and those that have been discovered in the site and plain of Troy; for which see these articles.

The Turkish empire in Asia is estimated at 470,400 

square miles, and the population at 10,000,000; which, allowing 
8,000,000 for the European part, will render the total 
18,000,000. The reader will find a sketch of the manners 
and customs of the inhabitants of Asiatic Turkey under 
this article, which we shall now proceed to mention. The 
Curds or Kurds pass in summer from Moufoul to the 
Sources of the Euphrates, and they are never punished 
either for robbery or murder. They are a pastoral people, 
who conduct their herds from one country to another, and 
extending sometimes as far west as Tocato; where Toursn 
fort, in his time, found other hordes called Tourkomans. 
The Armenians, though Euychian Christians by profession, 
and of course irreconcilable enemies of the Greeks, 
are distinguished by many singular manners and customs. 
They are represented as a servile and polite people; and 
by their frugality and enterprize, are admirably qualified for 
conducting the Levant trade, which is chiefly their province. 
For an account of the Druzes and Maronites, see these 
appellations. In the northern extremities of Asiatic Tur 
key, there are many tribes which have adopted singular 
practices. Six or seven languages are said to be spoken in 
the country between the Euaxine and the Caiphan. The 
Abkhass, called by the Circassians “ Kuh-Hafip,” a people 
beyond the mountains, retain some traces of Christianity. 
The territory of the Tcherkasses, or Circassians, is ex 
tensive: part of it is subject to Ruffia, but their manners 
are invariable. The princes cannot possess lands, and their 
nobles are chosen by the princes from the vaflals, or third 
class. Public measures are proposed by the prince, and 
debated by the nobles and deputies of the people, on a spit 
denied for this purpose, near the royal residence. The 
agriculture of these people is barely sufficient for their own 
consumption; but they export sheep and borbes, and 
flaves taken in their predatory excursions. The beauty of 
their women has been much extolled. Having received a 
fituitable education, and formed from their youth according 
to their own standard of beauty, they are fold from 20l. to 
100l., and sometimes at a much higher price. Soon after 
the birth of a girl, a belt is twined round her waist, and when 
this bursts, it is replaced by a second; so that their waists 
become very small, and their shoulders broad, which is a 
defect little regarded, on account of the beauty of their 
breasts. On the wedding-night the belt is cut by the huf 
band with a dagger, an operation which is sometimes ac 
cidentally fatal. The bridegroom pays for his bride a 
premier, or “ kelim,” consisting of arms, or a coat of mail; but he must not then, nor on any future occasion, lie 
him, or cohabit with her, without the greatest mystery. 
The young men recommend themselves by their activity 
and address in military exercises; and those who are most 
alert have the privilege of choosing the most beautiful part 
ers. Their musical instriments are a long flute, with only 
three stops, a species of mandoline, and a tambourine. 
Their dances are in the Asiatic style, with little gaiety or 
expression. The women pride themselves on the courage 
of their husbands, and feervously reproach them when they 
are defeated. It is their business to polich and take care of 
the armour of the men. The habitation of a Circassian 
fconsists of two huts, because the wife and husband are not 
expected to live together at meals the whole family is 
affemblcd. Their food consists only of a little meal, pale 
made of millet, and a kind of fermented beer, prepared 
with the fame grain. The Mamelukes of Egypt are flaves 
regularly imported from Circassia and Georgia. In 
Imerita, Mingrelia, and Guriel, as well as in Georgia, 
which forms a Persian province, the barons have power 
of life and death over their vaflals, and form a very 
powerful aristocracy, very formidable to the prince, who 
refides at Cutais. The religion of all these provinces is the 
Greek; but they can scarcely be regarded as subject to 
Turkey. It may be observed in general, after this brief 
detail, that the most striking feature of manners and cus 
toms in the Turkish empire, is that half the people may 
be considered as somewhat civilized, while the other half 
may be regarded as pastoral wanderers ranging over ex 
tensive waftes. Next to the capital of the Turkish empire, 
the next city of Asiatic Turkey in dignity and importance 
is Aleppo, containing about 250,000 inhabitants, where 
the manufactures of flax and cotton are flourishing, and 
whither large caravans frequently resort from Bagdad and 
Baghara, with the products of Peria and India. Damar 
cus is supposed to contain 180,000 souls: Smyrna may be 
regarded as the third city in Asiatic Turkey, and contains 
about 120,000 souls: Prufa is a beautiful city at the 
northern bottom of mount Olympus, and its number of in 
habitants is estimated at about 60,000: Magnifi, or Mag 
ifiea, is also a city of some repute in this quarter of the 
empke; and Kircagatch has rifen to importance by the 
cultivation of cotton, being situated about 40 miles N.E. 
of Magnifi, on the route to Prufa: Angora contains 
80,000 inhabitants, and trades chiefly in yarn for shawloons, 
and in Angora stuffs of its own manufacture from the 
hair of a breed of goats: Tokat is flourishing, and its 
inhabitants are about 60,000; its manufactures are falk and 
leather, and chiefly copper utensils: Bafra, or Baghara, on 
the cliffary of the Euphrates and Tigris, contains 
about 50,000 inhabitants, and is a place of great con 
sequence; as the various products of Europe and hales 
are here exchanged for those of Peria; and opulent 
carcans.
caravans proceed from this most central point of the Oriental trade to the chief cities of Asiatic Turkey:— Baghdad, the seat of the caliphs, and scene of many Eastern fictions, is now reduced to a town of about 40,000 inhabitants:— the ancient and celebrated city of Jerusalem is now a mean town, chiefly depending on the piety of pilgrims; and towards the frontiers of Persia frequent wars have spread depredation; nevertheless Erzeroum, the capital of Armenia, has till about 25,000 inhabitants; but Kars, the extreme town upon the frontiers of Persia, though tolerably fortified, is an inconvenient place. The chief articles of commerce in Asiatic Turkey are carpets, rubarb, and several other drugs. The Levant or Turkey trade was formerly of great consequence to Great Britain; but from the middle of last century it has been more advantageous to France. The state of the Levant trade chiefly carried on at Smyrna appears from the following documents:

France sends coffee, sugar, indigo, cloths, and cochineal.
England, shalloths, muffins, iron, tin, spices, refined sugars.
Holland, muffins, India goods, cloths, spices.
Austria, from Trieste, cloths, glafs, hard-wood, linen, wood, amber.
Ruffia, iron, corn, caviare, dried fish, furs.
Italy, filks and velvets, wax and paper.
European Turkey, wines, filks, tobacco.
Italy, silks and velvets, cottons, filks, drugs.
Egypt, coffee of Yemen, rice.
Barbary, dates, woolen caps from Tunis, butter, wax.

The port of Marsailles, which carries on the French trade with Smyrna, draws the wool and cochineal from Spain; but this country has lately begun to conduct her own commerce. Venice, under the Austrian power, might become the chief port of the Levant buttles. Of the French commerce, the chief staple is coffee: but this cannot be resumed with much vigour till France shall acquire a greater naval power.

Upon the whole, says Pinkerton, if the commerce of Smyrna be at present valued at fifty millions of francs, the English trade for thirty millions, the Dutch for ten, while France shares the remaining ten millions with the emperor, Italy, and other states above-mentioned.

The climate of Asia Minor has been always considered as excellent. The heat of the summer is tempered by numerous chains of high mountains, some of which are covered conflantly with snow. The aspect of Asiatic Turkey is mountainous, intermingled with spacious and beautiful plains, which afford pasture to the numerous flocks and herds of the Turkmans. The foil is various; but the chief agricultural products are wheat, barley, and durra. It abounds also with grapes, olives, and dates. In Syria the agriculture is deplorable, and the pastures are in a wretched condition, being fold, as in Poland, with the foil, and their constant fare being barley bread, onions, and water.

The principal river of Asiatic Turkey is the Euphrates, the course of which may be estimated at about 1,400 British miles: next in importance is the Tigris, whose course is about 800 miles; and both these rivers are navigable to a considerable distance from the sea. The third river is called by the Turks Kizil Irnak, the celebrated Haly's of antiquity, rising in mount Taurus, and discharging itself into the Euxine sea on the W. of the gulf of Sanloum: the river Sacaria, or ancient Sangarius, rises about fifty miles S. of Angora, and joins the Euxine about seventy miles E. of Constantinople: next in rank is the Mazander, rising N. of Apamnea, and winding its course about 350 British miles: the Sarabat is the ancient Hermus, famous for its golden sands. The chief river of Syria is the Orontes, now called Oron or Af, which runs into the Mediterranean.

The lakes of Asiatic Turkey are numerous. The most remarkable are the Van and Urmiah: others are the Dead sea in Syria, fifty miles long, and twelve or thirteen in breadth: that of Rackama, S. of Hilla and the ancient Babylon, about thirty miles long, and flowing into the Euphrates: the Tatta, or Palus Salla of D'Anville, a saline lake about seventy miles long, and one or two in breadth towards the centre of Asia Minor, being the modern Toulfa or salt lake: that of Ulubad in Natolia, anciently denominated the lake of Apollonia, twenty-five miles in circumference, and in some places seven or eight miles wide, sprinkled with several islands and peninsulas, and the grand receptacle of the waters from mount Olympus: the largest of these lakes is called Abouillaou, probably from the ancient name of the city which flood upon it: and about fifty miles to the N.E. was the lake anciently called Ascadius, now Ilnik.

The mountains of Asiatic Turkey are of ancient celebrity: such are the Taurian chain; the Caucasian mountains, ranging from the mouth of the river Cuban in the N.W. to the place where the Kur enters the Caffian in the S.E., and furnishing various chains, such as the Antitaurus of antiquity, and others branching out into Peria; mount Taurus, terminating at the Euphrates and desarts of Algæira: the chain of Taurus is now called Kuren, and extends about 600 miles E. and W. from the Euphrates to the vicinities of the shores of the Archipelago. These and other mountains of Asiatic Turkey are conjectured to be calcareous; while the Caucasus alone aspires to the rank of a granitic or primitive chain. Towards the E. of Armenia is Ararat, properly belonging to Peria; and beyond Ararat are branches of the Caucasian chain, to which probably belongs the mountains of Elwend, or Niphates of antiquity. In Syria, the most celebrated mountains are Lebanon or Levanon, and Antilibanus. On the eastern side of the Archipelago was Olympus (now Kefik Dag); and 140 miles W. of Olympus is mount Ida, the branch of which was called by the ancients Garganus, which gave source to the Granicus, the Simois, and other rivers, most of which directed their course to the N., and extended in western prominences to the Hellepont, amidst which was situated the celebrated city of Troy. Other remarkable mountains of this classical shore, as it has been denominated, were those of Rhod and Tenedus, &c. &c. S. of the Mæander, the Taurus detaches a chain called Cadmus and Grus, bending towards the isles of Cos and the Cyclades. The numerous mountains of Asiatic Turkey are frequently clothed with immense forests of pines, oaks, beeches, elms, and other trees; and the southermost shores of the Black sea present many gloomy forests of great extent. The inhabitants are hence supplied with abundance of fuel, in defect of pit-coal, which has not been explored in any part of Asiatic Turkey. Sudden conflagrations arise from the heatless waste of the caravans, which, instead of cutting off a few branches, set fire to a standing tree. The extensive provinces of Natolia, Syria, and Melopotamia, have been little accessible to European curiosity, since their reduction under the Turkish yoke. In Pinkerton's Geography we have a catalogue of those plants and trees that have been found wild in the Asiatic part of the Ottoman territory. Several dyeing drugs and articles of the materia medica are imported from the Levant, among which are madder, and a variety called alizar, which grows about Smyrna, and affords a much finer red dye than the European kind; jalap, commony, febechen, the ricinus, yielding
yielding by expression caflor oil, squiring cucumber, coloquintida, opium poppy, and spiadenard. The best
horses in Aliatic Turkey are of Arabian extract; but mules
and asses are more generally used. The beef is scarce and
bad, the mutton superior, and the kid a favourite repast.
Other animals are the bear, tiger, hyena, wild boar, jackal,
and dogs in great abundance. On the funiments of Caeceafus
is found the ibex, or rock-goat; at Angora, singular goats
and cats; the gazelle, and deer and hares in great abundance
are found in Asia Minor. The partridges are generally of the
red-legged kind, larger than the European: Hfh is plentiful
and excellent. The mineralogy of these extensive provinces
has not been yet sufficiently explored. The most noted min-
eral waters are those of Prufa, at the bottom of Mount
Olympos: the baths are splendid, and paved with marble.
Walachia furnishes many other hot-springs.

The chief islands belonging to Aliatic Turkey, situated
in the Archipelago, are Mitylene, Scio, Samos, Cos, and
Rhodes. Along the southern shores of Asia Minor are
some small islands, such as that of Cafel Rozlo, S.E. of Pa-
tira; but these are of no moment compared with Cyprus,
about 160 miles long and nearly 70 at its greatest breadth;
The chief cities of which are Nicofia and Famagutta.

Some geographers, in opposition to the testimony of trav-
ellers, have considered Egypt as a Turkish province;
whereas it was only occasionally tributary, and subject to
the military arithracy of the bey. Some of the maritime
Mahometan powers have likewise affiffed the Porte with
ships in time of war; but they cannot be regarded as sub-
ject to the Ottoman feapte.

TURKEY. Coinage, &c. of.

As the Turks, though aspir-
ing to a very ancient derivation, comprehending Tartars
and Moguls, (see TURK,) are merely a mixture of Sar-
mate or Slavi, Arabs and Greeks, which began to form a
nation in the fourteenth century, they seem to have issued
currences till they feized Constantinople in 1453; and their coins
resemble those of Persia and Arabia, having merely inscrip-
tions on both sides. Turkey keeps accounts in piafures,
commonly called grouch by the Turks, and by the English
dollars. Each piafure is divided into 40 paras, and each para
into 3 aspers. Sometimes, instead of these real coins, the
piafure is divided into 80 or 100 imaginary parts, called aspers,
or paras. Jux or jock is a sum of 100,000 real aspers.
A chief or purfe is 500 ditto. The gold coins of Turkey
are the fequin or chequen (see SEKON): the silver coins
are the two-dollar piece of 80 paras; the altmicchole of 60 paras;
the dollar or piafure of 40 paras; the zoletta or izelotta
of 30 paras; the roup of 10 paras; the hellick of 5 paras;
the para of 3 aspers; and the asper. The Turkish coins,
notwithstanding the regulations of 1780, when a single
piafure weighed 52 drachms, or 277 English grains, have
been gradually deteriorated; so that a piafure of the lately coined,
weighed and faiyed by the king's aflay-master of the Mint,
was reported to be as follows: weight 8 dwts. 6 grs., fine-
enfs 502. 6 dwts. worse than the English standard; hence
its fineness was 47 car. 2 grs. Turkish, and its value in
fcs. 13d. in the old round.
The Turkish cheque or pound, with which gold, filver,
diamonds and precious fones are weighed, is divided into
100 drachms, and the drachm into 16 kilotts or carats, or
4 grains. A cheque weighs 10 oz. or 5 dwts. 3 grs. true
weight, and a drachm 491 grs. ditto; so that 48 cheques
weigh 4 lbs. troy very nearly.
The cantaro, quintal or kintal contains 44 okes, or 100
rotoli; the oke, 4 yuflromes or cheques, or 400 drachms;
the rotolo, 176 drachms. A metecal is 1 f. drachm. The
kintal of cotton-yarn is 45 okes.

The cantaro weighs about 123 lbs. avoirdupois; the oke,
2 lbs. 13 oz.; the rotolo, 191 ounces; the cheque, 174
ounces avoirdupois.

Silks from Perfa are weighed by the batman of 6 okes,
or 2400 Turkifh drachms, or 161bs. 14 oz. avoirdupois:
from Brufa are weighed by the taffee of 610 Turkifh
drachms, or 4 lbs. 4 oz. 10 drs. avoirdupois.

The cheque of goats' wool is 800 Turkifh drachms,
or 5 lbs. 10 oz. avoirdupois; the cheque of optium 250 Turkifh
drachms, or 27 oz. 10 drs. avoirdupois.

Corn is measured by the quillot or killo, weighing, in wheat,
about 22 okes, or 60 lbs. avoirdupois; 4 killos make 1 forin:
8^1 killos answer nearly to 1 English quart. A killo
of rice is 10 okes.

Oil and other liquids are sold by the meter, or almad:
the meter weigh 8 okes, or 224 lbs. avoirdupois; and 8
almuds equal 11 English gallons.

The pic or pike is of two forts; the longest, called halbebi
or archim, with which silks and woollens are measured,
is 314 French lines, or 27-, English inches long; the other,
called endaffe, with which cotton goods and carpets are
measured, is 3 per 100 shorter. But, in the general course
of European trade, the pike is reckoned at 3ths of a French
yard.

The exchanges of Constantinople with the principal com-
mercial places in Europe are as follow: Constantinople

gives
Amsterdam 60 paras, more or less, for 1 florin current.
Genoa 23 paras, more or less, for 1 lira fuori banco.
Hamburgh 1 piafure, for 24 grotes Flemifh banco, more or
less.
Leghorn 145 paras, more or less, for 1 peseta of 8 reali.
London 18 piafures, more or less, for 1l. sterling.
Marfelles 1 piafure for 1 franc 45 centimes, more or less.
Naples 120 paras, more or less, for 1 ducat regno.
Paris 210 piafures, more or less, for 100 ecos of 3 livres,
or 300 francs.

Venice 36 paras, more or less, for 1 sequin of 22 lire
p lucki.

Vienna and Trieffe 50 paras, more or less, for a florin
current.

The exchanges between Constantinople and other trading
places, where Turkish money is used, are done at a premium
of 10 per cent. more or less, in favour of Constantinople.

Bills between Constantinople and the principal trading
places of Europe are commonly drawn at 31 days' flight;
but from one place, in Turkey, on another, at 11 days' flight.
Some European merchants pay their bills on the very day
on which they become due; and others take as many days
as are allowed in their respective countries.

Trieffe keeps accounts in florins or florins of 60 crowners;
also in lire of 20 foldi; the crowner being subdivided into
4 pfennings, and the foldo into 12 denari. These monies
of account are valued in Austrian currency, in Trieffe currency,
and in Valuta di Piazza: the first is chiefly used in foreign
exchanges, the second in wholesale trade, and the third in
retail business. A florin Austrian currency is worth 51/2
lire of Trieffe currency, or 5½ on lire di piazza. For the coins,
see VIEIIA.

Tripoli keeps accounts in piafures of 13 grimmelli, or 52
aspers: the grimmelin is valued at 6 sous Tournois, which
makes the piafure of Tripoli worth 31. 3d. Sterling. The
weight for gold and filver is called Meftad (which see):
50 of which are equal to a Venetian mark; so that 1 metad
weighs 7½ English grains. The cantaro weight contains
100 rotoli, each of 6 ounces, or 128 termini; the cantaro

TURKEY, a town of the iflate of New Jefery; 13 miles
N.N.W. of Amboy.

TURKEY Creek, a river of South Carolina, which runs
into the Cangaree, N. lat. 34° 55’. W. long. 81° 35’.—
Also, a river of America, which runs into the Ohio, N. lat.
38° 32’. W. long. 85° 12’.

TURKEY Foot, a township of Pennfylvania, in Somerfeet
county, containing 975 inhabitants.

TURKEY Hill, a township of Illinois territory, in the
county of St. Clair, containing 1131 inhabitants.

TURKEY Point, a cape on the coaft of Maryland, at the
mouth of the Susquehanna, where it takes the name of Chifa-
peak. Here the British army landed in August 1777, as
they were advancing to Philadelphia; 16 miles S.E. of
Elkton.—Also, a cape on the N. coaft of lake Erie.

TURKEY River, a river of Louisiana, which runs into the
Missifippi, N. lat. 42° 10’. W. long. 91° 55’.

TURKEY Town, a town of the iflate of Georgia; 60 miles
N. of Oakoflee.

TURKEY, Meleagris, in Ornithology, a diftinct genus of
birds, of the order of the Gallinæe. For the diftinguifhing
characters and species, fee Meleagris.

Wild turkeys prefervc a famenefs of colouring; the tame
vaying; but the black approaching neareft to the original
flock. Of late a beautiful kind has been introduced into
England of a fwoy whitenes, finely contrafting with its
red head. The utual weight of the wild turkey is about
30 lbs.

The pinions of the males are strongly exprcfe by the
change of colours in the flegy fubflance of head and neck,
which alters to red, white, blue, and yellowifh, as they are
differently affecfed. One cock ferves many hens, who retire
to an obfufe place in order to fit, the cock being apt to
break the eggs. The females are very affectionate to their
young, and though the eggs addle, will almof perish with
hunger, unlefs they are removed, before they will quit the
neft.

Turkies delight much in the feeds of nettles, but thofe of
the purple fox-glove are fatal to them. They are ftrupid,
quarrelfome, and cowardly birds; they are swift runners,
but indifferent flyers; they love to perch on trees, and in a
wild fatc, get fo high as to be beyond the reach of the
mufket.

In the fafte of nature they go in flocks, even of five hun-
dred, and feed much on the small red acorns, frequenting the
fwavps of their native country, where they rooff, but at
fun-rifing repair to the dry woods in search of acorns and
berries. The flefh of the wild turkey is faid to be prefetable
to that of the tame, but redder.

Wild turkeys are now very rare in the inhabited parts of
America, but are found in numbers in the dillant and moft
ufrequently fots.

The Indians make a very elegant clothing of the feathers,
withfing the inner webs into a ftrong double thread of hemp,
or inner bark of the mulberry-tree, and working it like
matting; it appears rich and glosfly, and as fine as a filk
fcaf. They alfo make fans of the tail, and the Trench of
Louisiana were wont to make umbrellas by the junétion of
four of the tails.

Turkies are natives only of America, or the New World,
and of curfe unknown to the ancients: this is a point which
Mr. Pennant has eftabilifhed by an elaborate induction of
various particulars in the history of these birds; evincing
that they are natives neither of Europe, Asia, nor Africa.
The firft precise defcription of them is given by Oviedo, in
1525; they are also mentioned as natives of the main land
of the warmer parts of America, by Fernandez, physician to
Philip II. who wrote between the years 1555 and 1598: they
were alfo frequently seen, both in their wild and tame ifte, by
Dampier, in the province of Yucatan, now a part of
Mexico.

In North America they were oberved by the firft disco-
veryers. They were firft introduced into Europe from Mexico
or Yucatan, and imported into England, probably from Spain,
as early as the year 1524. Since that period they have been
ufefullly cultivated in this kingdom, fo that in the year
1585 they made a dift even in our rural fefs. But in
France they were fo rare, that the firft which was eaten in
that kingdom appeared at the nuptial feast of Charles IX.

TURKEY Leather. (See MOROCCO Leather.) The pro-
ceffes for dyeing leather red and yellow, as prafticed in Tur-
key, with the directions for preparing and tanning the skins,
as communicated by Mr. Philippo, a native of Armenia, who
obtained 100l. and a gold medal from the Society for the
Encouragement of Arts, as a reward for the difcovery,
as follows.

1. Firft Preparation of the Skins, both for Red and Yellow
Leather, by drefling them in Lime.—Let the skins, dried with
the hair on, be firft laid to soak in clean water for three days;
then let them be then thrown over the flefh-fide, put into ftreath-
water for two days longer, and afterwards hung up to drain
half an hour. Let them now be broken on the flefh-fide,
lined in cold lime on the fame fide, and doubled together
with the grain-fide outward. In this ifte they muft be
hung up within-doors over a frame for five or fix days, till
the hair be loose; which muft then be taken off, and the
skins returned into the lime-pit for about three weeks. Take
them out, and let them be well worked flefh and grain, every
sixth or feverf day during that time; after which, let them be
washed ten times in clear water, changing the water at
each washing. They are next to be prepared in drench, as
below mentioned.

2. Second Preparation of the Skins for both the Red and Tel-
low Dyes by drenching.—After squeezing the water out of
the skins, put them into a mixture of bran and water, warm
as new milk, in the following proportions; viz. about three
pounds of bran for five skins, and water fufficient to make
the mixture moderately fluid, which will be about a gallon
to each pound of bran. In this drench let the skins lie three
days; at the end of which time they muft be well worked,
and afterwards returned into the drench two days longer.
They muft then be taken out and rubbed between the hands;
the water fqueezed from them, and the bran scraped off clear
from both fides of the skins. After this they muft be again
washed ten times in clear water, and the water fqueezed out
of them.

Thus far the preparatory procefs of all the skins, whether
intended to be dyed red or yellow, is the fame; but after-
wards thofe which are to be dyed red, must be treated as
follows.

3. Preparation in Honey and Bran of the Skins that are to
be dyed Red.—Mix one pound of honey with three pints of
lukewarm water, and flir them together till the honey is
diſsolved.
dissolved. Then add two double handfuls of bran; and taking four skins (for which the above quantity of the mixture will be sufficient), work them well in it one after another. Afterwards fold up each skin separately into a round form, with the flesh-side inwards; and lay them in an earthen pan, upon another pan; if in the summer, by the fire for each other; but in the winter, on the top of each other. Place the vessel in a flopping position, so that such part of the fluid as may spontaneously drain from the skins, may pass from them. An acid fermentation will then rife in the liquor, and the skins will swell considerably. In this state they must continue for seven or eight days; but the moisture that drains from them must be poured off once or twice a day, as occasion may require. After this a further preparation in salt is necessary; and which must be performed in the following manner.

4. Preparation in Salt of the Skins to be dyed Red.—After the skins have been fermented in the honey and bran, as above-mentioned, let them be taken out of that mixture on the eighth or ninth day, and well rubbed with dry common sea-falt, in the proportion of about half a pound to each skin; the salt must be well rubbed and worked with them. This will make them contract again, and part with a further confiderable quantity of moisture: which must be fqueezed out by drawing each skin separately through the hands. They must next be scraped clean on both sides from the bran, superfluous salt, and moisture that may adhere to them. After which dry salt must be fwered over the grain-side, and well rubbed in with the hand. They are then to be doubled, with the flesh-side outwards, lengthwise from neck to tail, and a little more dry salt must be thinly fwered over the flesh-side, and rubbed in; for the two last operations, about a pound and a half of salt will be sufficient for each skin. They must then be put, thus folded on each other, between two clean boards, placed floping, breadthwise; and a heavy weight laid on the upper board, in order gradually to press out what moisture they will thus part with. In this state of preffure, they must be continued two days or longer, till it is convenient to dye them, for which they will then be duly prepared.

5. Preparation of the Red Dye, in the proper Proportion for four Skins.—Part eight gallons of water into copper, with seven ounces of fhanen tied up in a lien bag. [fshanen is a drug much used by dyers in the East; and may easily be procured at any of the ports of Syria and Africa, in the Levant. It is the Eastern joined kali, called by botanists falicornia; and grows in great plenty in thofe and other parts of the East.] Light a fire under a copper; and when the water has boiled about a quarter of an hour, take out the bag of fhanen, and put into the boiling fluid or licivium, 19, two drachms of album; 2dly, two drachm pomegranate bark; 3dly, three quarters of an ounce of turmeric; 4thly, three ounces of cochineal; 5thly, two ounces of loof-fugar. Let the whole mixture boil about six minutes, then cover the fire, and take out a quart of liquor, putting it into a flat earthen pan; and when it is as cold as new milk, take one skin, folded lengthwise, the grain-side outwards, and dip it in the liquor, rubbing it gently with the hands. Then taking out the skin, hang it up to drain, and throw away the superfluous dye. Proceed in the fame manner with the remaining three skins; repeating the operation of each skin separately, eight times, fqueezing the skins by drawing them through the hands before each fresh dipping. Lay them now on one side of a large pan, set floping, to drain off as much of the moisture as will run from them without preffure, for about two hours, or till they are cold; then tan them as below directed.

6. Tanning the Red Skins.—Powder four ounces of the

beft white galls in a marble mortar, fifting it through a thin sieve. Mix the powder with about three quarts of water, and work the skins well in this mixture for half an hour or more, folding up the skins fourfold. Let them lie in this tan for 24 hours; when they must be worked again as before; then taken out, scraped clean on both fides from the first galls, and put into a liquidity of fresh galls and water. In this fresh mixture they must be again well worked for three quarters of an hour; then folded up as before, and left in the frefh tan for three days. On the fourth day they must be taken out, washed clean from the galls in seven or eight fresh quantities of water, and then hung up to dry.

7. Manner of dressing the Skins after they are tanned.—When the skins have been treated as above, and are very near dry, they should be fqueezed with the proper instrumet or fcraper on the fleshy-side, to reduce them to a proper degree of thickness. They are then to be laid on a smooth board, and glazed by rubbing them with a smooth glafs. After which they must be oiled, by rubbing them with olive-oil, by means of a linen rag, in the proportion of one ounce and a half of oil for four skins: they are then to be grained on a grain-board, breadthwise, breadthwise, and cornerwise, or from corner to corner.

8. Preparations with Galls, for the Skins to be dyed Yellow.—After the four skins are taken out of the drench or bran, and clean wafhed as before directed in the second article, they must be very well worked, half an hour or more, in a mixture of a pound and a half of the beet white galls, finely powdered, with two quarts of clear water. The skins are then to be separately doubled lengthwise, rolled up with the flesh-side outwards, laid in the mixture, and clofe preffed down on each other, in which state they must continue two whole days. On the third day let them be again worked in the tan; and afterwards scrape clean from the galls, with an ivory or brafs instrumet (for no iron must touch them). They must then be put into a fresh tan, made of two pounds of galls finely powdered, with about three quarts of water, and well worked therein fifteen times. After this they must be doubled, rolled up as before, and laid in the second tan for three days. On the third day, a quarter of a pound of white sea-falt must be worked into each skin; and the skins doubled up as before, and returned into the tan, till the day following, when they are to be taken out, and well wafhed fix times in cold water, and four times in water lukewarm. The water must be then well squeezed out, by laying the skins under preffure, for about an hour, between two boards, with a weight of about 200 or 300 pounds laid upon the uppermost board, when they will be ready for the dye.

9. Preparation of the Yellow Dye, in the proper Proportion for four Skins.—Mix fix ounces of caffiari gebara, or dgebara, or the berries of the Eastern rhammus, with the same quantity of album; and pound them together till they be fine, in a marble or brafs mortar, with a brafs pefle. [The caffiari gebara is the berries of an Eastern rhammus, or buckthorn-tree; and may be had at Aleppo, and other parts of the Levant, at a small price. The common Avignon or yellow berries may be fubstituted, but not with so good an effect; the caffiari gebara being a ftronger and brighter yellow dye, both for this use and all that of colouring paper-haungings, &c.] Then dividing the materials, thus powdered, into three equal parts of four ounces each, put one of those three parts into about a pint and half of water, in a china or earthen vessel, and flir the mixture together. Let the fluid stand to cool, till it will not fteal the hand. Then spreading one of the skins flat on a table, in a warm room, with the grain-side
side uppermoft, pour a fourth part of the tainting liquor, prepared as above directed, over the upper or grain-side, spreading it equally over the skin with the hand, and rubbing it well in. Afterwards do the like with the other three skins, for which the mixture first made will be sufficient.

This operation must be repeated twice more on each skin separately, with the remaining eight ounces of the powder of the berries and alum, with the above-mentioned due proportions of hot water, put to them as before directed.

The skins, when dyed, are to be hung up on a wooden frame, without being folded, with the grain-side outwards, about three quarters of an hour to drain; when they must be carried to a river or stream of running water, and well washed therein six times or more. After this they must be put under pressure for about an hour, till the water be well squeezed out; afterwards the skins must be hung up to dry in a warm room.

This being done, the skins are to be dried and grained as before directed for those dyed red; except the oiling, which must be omitted.

The processes for dressing and preparing the skins of lambs, sheep, goats, and other thin hides are various, according to the nature of the article. This branch of the manufacture supplies the large demand of white and dyed leather for gloves, the leather called morocco of different colours and qualities, used for coach-linings, book-binding, pocket-books, &c. This leather is applicable to a variety of other purposes. The white leather is not tanned, but finished by the mere processes of tawing; but the coloured leather receives a tanning, generally by fumach, indenpendent of the other materials. The preparation of each, or that in which the skin is thoroughly cleaned and reduced to the state of simple membrane, in which it is called felt, is essentially the same, whether for tawing or dyeing. It is thus performed at the best manufactories at Bermondsey, near London, a place long celebrated for all branches of the leather business.

By far the greater number of the skins are imported: if lambs, they are thus prepared; the skins are first soaked for a time in water, to cleanse them from any loose dirt and blood, and put upon the beam commonly used for the purpose, which is a half cylinder of wood covered with strong leather, and lashed upon the flesh-side with the femurcular blunt knife fibres with two handles, used in this operation. They are then hung up in considerable numbers in a small close room heated by flues, where they remain to putrefy for a given time. During this process a thick fitful flame works up to the surface of the skin, by which the regularity of the process is judged of; and the wool is loosened, so that it readily comes off with a slight pull. Each skin is then returned to the beam, the wool taken off and preferred, and all the flane worked off with the knife, and the rough edges pared away. The skin is then put into a pit filled with lime-water, and kept there from two to five weeks, according to the nature of the skin, which has the effect of checking the further putrefaction, and produces a very remarkable hardening and thickening of its substance, and probably also it detaches a further portion of the flane. The skin is again well worked upon the beam, and much of its substance pared down, and all inequalities smoothed with the knife. Much pains and judgment are required in these operations, on the one hand not to endanger the substance of the skin by the putrefaction (which if carried on too long would soon reduce it to an incohesive pulp), and on the other hand to work out every particle of the flane, of which the leaf, if retained, will prevent the skin from dressing well in the frequent processes, and from taking the dye uniformly and well. The skin is then again softened and freed from the lime by being thrown into a vat of bran and water, and kept there for some weeks in a state of gentle fermentation, being occasionally returned to the beam. All the thickening produced by the lime is thus removed, and the skin is now highly purified, and is a thin extensible white membrane, called in this state a pelt, and is fit for any subsequent operation of tawing or dyeing, or oil dressing, or shammaging.

The method of bringing kid and goat's skins to the state of pelt is nearly the same as for lambs, except that the liming is used before the hair is taken off, the hair being of but little importance, and only fold to the plaiters; but the lamb's wool, which is more valuable, would be injured by the lime. Kids'skins will take a longer time in tanning than lambs'.

If the pelts are to be tawed, they are put into a solution of alum and salt in warm water, in the proportion of three pounds of alum and four pounds of salt to every 120 middle-sized skins, and worked about therein till they have absorbed a sufficient quantity. This again gives the skin a remarkable degree of thicknees and toughness.

The skins are then taken out and washed in water, and then again put into a vat of bran and water and allowed to ferment for a time, till much of the alum and salt are got out; and the usual thickening produced by it is for the most part reduced. They are then taken to a lofty room with a stove in the middle, and stretched on hooks and kept there till fully dry. The skins are then converted into a tough, flexible, and quite white leather; but to give them a glossy finish, and to take off the harthness of feel still remaining, they are again soaked in water to extract more of the salt, and put into a large pail containing the yolks of eggs beat up with water. Here the skins are trodden for a long time, by which they are completely imbibe the substance of the egg, that the liquor above them is rendered almost perfectly limpid, after which they are hung up in a loft to dry, and finished by g loosening with a warm iron. There are other smaller manipulations, which need not be here mentioned.

The essential difference therefore between tanning and tawing is, that in the former the pelt is combined with tan and other vegetable matter, and in the latter with something that it imbibes from the alum and salt (possibly alumine), and which is never again extracted by the subsequent washing and browning.

The morocco leather prepared chiefly from sheep's skins and used for coach-linings, the best kind of book-binding, &c. is prepared by the following processes. The skin, cleaned and worked in the way already described, is taken from the lime-water, and the thickening thereby occasioned is brought down, not by bran liquor as in tawing, but by a bath of dogs' or pigeons' dung diffused in water, where it remains till sufficiently suppled, and till the lime is quite got out, and it becomes a perfectly white clean pelt. If intended to be dyed red, it is then fewed up very tight in the form of a sack, with the grain side outwards (the dye only being required on this side), and is immersed in a cochineal bath of a warmth juft equal to what the hand can support, and is worked about for a sufficient time till it is uniformly dyed, a procés which demands much skill and experience. The sack is then put into a large vat containing fumach infused in warm water, and kept for some hours till it is sufficiently tanned.

The skins intended to be blacked are merely fumached without any previous dyeing. After some further preparation, the colour of the fine red skins being finished with a weak
weak bath of saffron, the skins when dry are grained and polished in the following way. They are stretched very tight upon a smooth inclined board, and rubbed over with a little oil to imitate them. Those intended for black leather are previously rubbed over with an iron liquor, by means of a flint brush, which unites with the gallic acid of the umach, infamously strikes a deep and uniform black. They are then rubbed by hand with a ball of glass cut into a polygonal surface, with much manual labour, which polishes them and makes them very firm and compact.

Lastly, the graining or ribbed surface by which this kind of leather is distinguished, is given by rubbing the leather very strongly with a ball of box-wood, round the centre of which a number of small equi-distant parallel grooves are cut, forming an equal number of narrow ridges, the friction of which gives the leather the desired inequality of surface.

The procés for the real morocco leather, as prepared from goat-skins at Fez and Tetuan, is thus described by M. Broussonet. The skins are first cleaned, the hair taken off, limed and reduced with bran, nearly in the way already described for the English morocco leather. After coming from the bran they are thrown into a seconf bath made of white fks, mixed with water, which is thereby rendered limy and fermentable. In this bath the skins remain four or five days, when they are thoroughly salted with ful-gen (or rock-salt) alone (and not with salt and alum), after which they are fit to receive the dye, which for the red is cochineal and alum, and for the yellow, pomegranate bark and alum. The skins are then tanned, dressed, fuppled with a little oil, and dried.

Much excellent leather of every kind is prepared in different parts of the Ruffian empire. The preparation of the fine Ruffia leather, so well known for its quality and for its peculiar smell, is described at large in Mr. Tooke's "View of the Ruffian Empire," to which we must refer the reader for the minuter particulars. In general it may be stated that the hides are first put into a weak alkaline ley to loosen the hair, and then scraped on a beam, then (if calves) are reduced by dogs' dung, and a four oatmeal drench, then tanned with great care and frequent handling. The bark ufed here is feldom oak, but, where it can be got, the bark of the black willow, or if this cannot be had, birch-bark. They are then dyed either red or black, thefe being the two colours the moft esteemed. For the red, the hide is first foaked in alum, and then dyed with Brazil wood. The black is given as usual with an iron liquor. The leather is then fmacd with birch-tar, which gives the peculiar smell so much prized (and which, when ufed for book-binding, has the valuable property of protecting the book from worms), and is finifhed by various other manipulations. The fleeced or barred surface is given to the leather by a very heavy iron cylinder round wound with riles. See VYFS.

A valuable faffion or dyed maroquin leather, almost equal to that of Turkey, is prepared largely at Atrafchan and other parts of Asiatic Ruffia. Only buck's* and goats' skins are ufed for this purpose. The favourable colours are red and yellow. The general method of preparing the peel is the fame as in this country for the dyed morocco leather, that is by lime, dogs' dung, and bran. Honey is also ufed after the braining. The honey is diffolved in warm water, and some of this liquor is poured on each skin spread out on wooden trays till it has imbibed the whole of the honey, after which it is set to ferment for about three days, and then falted in a strong brine and hung up to dry. The skin is then ready to receive the dye, which for red is made with cochineal and the fallafa ericoides, an alkaline plant grow-
Among these was the Turkman Ala-el-din, sultan of Iconium. Ala-el-din, advanced in life and harried by the Tartars of Genghis Khan, granted lands to the Turks under heretogrul, and even made their chief general of all his troops. Heretogrul proved himself deserving the confidence of the sultan, vanquished the Moguls, acquired still greater power and reputation, and transmitted his honours to his son Ofman, who received from Ala-el-din, successor of the former of that name, the Kofetan, drum, and horse-tails, which are symbols of command among all the Tartars. This Ofman, to distinguish the Turks, his followers, from the others, gave them the name of "Ofmanes," from which we have made Ottomans; which new name soon became familiar to the Greeks of Constantinople, from whom Ofman conquered a sufficient extent of territory to found a powerful kingdom. He soon bestowed on it that title, by assuming, in 1300, the dignity of sultan, which signifies absolute sovereign.

No one is ignorant in what manner his successors, the heirs of his ambition and activity, continued to aggrandize themselves at the expense of the Greeks; till, continually depriving them of whole provinces in Europe and Asia, they at length flung them up within the walls of Constantinople; and Mahomet II. son of Amurath, having taken that city in 1453, annihilated this branch of the Roman empire. The Turks, now finding themselves difengaged from the affairs of Europe, turned their ambitions arms against the southern provinces. Bagdad, subjugated by the Tartars, had been without caliphs for two hundred years, but a new power, established in Peria, had succeeded to a part of their domains; and another, formed in Egypt, so early as the tenth century, and subsisting, at that time, under the name of Mamlouks, had seizes on Syria.

The Turks determined to depose these two rivals. Bayazid, the son of Mahomet, executed a part of this plan, by taking Armenia from the Sodi of Peria, and Selim his son completed it, by the conquest of the Mamlouks. This sultan having drawn them near to Aleppo, in 1517, under pretext of defending their influence in the war with Peria, suddenly turned his arms against them, and took from them successively Syria and Egypt, whither he pur- sued them. From that time the Turks established themselves in that country; but they are not settled much among the villages. We rarely meet with any individuals of that nation, except at Cairo; there they exercise the arts, and occupy the religious and military employments. Formerly they also were advanced to posts under government, but, within the last thirty years, a tacit revolution has taken place, which, without taking from them the title, has deprived them of the reality of power. See Turk and Turkey.

Volney observes, that the language of the Turkmans is the same with that of the Turks, and their mode of life nearly similar to that of the Bedouin Arabs. Like them, they are pastoral, and consequently obliged to travel over immense tracts of land to procure subsistence for their numerous herds. But there is this difference, that the countries frequented by the Turkman being rich in pasturage, they can feed more cattle on them, and are therefore less disturbed than the Arabs of the desert. Each of their "ordus" (hence horda), or camps, acknowledges a chief whose power is not determined by fixed laws, but governed by custom and circumstances. It is rarely abused, because the society is compact, and the nature of their situation maintains sufficient equality among its members. Every man able to bear arms is anxious to carry them, since on his individual force depend both his personal safety, and the respect paid him by his companions. All their property consists in cattle, that is, camels, buffaloes, goats, and especially sheep. They live on milk, butter, and meat; which are in great abundance among them, and the surplus of which they sell in the towns and the neighbouring country, for they are almost able alone to supply the butcheries. In return, they take arms, clothes, money, and corn. Their women spin wool, and make carpets, the use of which is immemorial in these countries, and consequently indicates their manner of living to have been always the same. As for the men, their whole occupation consists in smoking, and looking after their flocks. Perpetually on horseback, with their lances on their shoulders, their crooked sabres by their sides, and their pill-boxes in their belts, they are expert horsemen and indefatigable folders. They have frequent differences with the Turks, who dread them; but as they are divided among themselves, and form separate camps, they do not assume that superiority which their combined forces would ensure them. The paladins of Aleppo and Damascus, which are the only parts of Syria they frequent, may be computed to contain about 30,000 wandering Turk- mans. A great number of these tribes past in summer, into Armenia and Caramania, where they find grazs in greater abundance, and return to their former quarters in the winter. The Turkmans are reputed Muffulmen, and generally bear the distinguishing mark, circumcision. But they trouble themselves very little about religion, and they have neither the ceremonies, nor the fanaticism of federate nations. As for their manners, to describe them accurately, it would be necessary to have lived among them. They have, however, the reputation of not being robbers, like the Arabs, though they are neither less generous, nor less hospitable than they; and when we consider that they live in plenty, without being rich, and are inured to war, and hardened by fatigue and danger, we may presume they are equally removed from the ignorance and servility of the pashas, and the corruption and selfishness of the inhabit- ants of the towns. See TRUCHEMENIANS.

TURLACH-MORE, i.e. the Great Turlach, in the county of Galway, Ireland, a kind of lake, formed by the expansion of the rivers Clare and Moyne, which is upwards of six miles in length, and two in breadth; but which in summer, from the water being carried off by subterranean paf- fages, becomes a beautiful and found sheep-walk.

TURLAH, a town of Hindoostan, in the circuit of Ciacole; 25 miles E. of Kiemey.

TURLOS, a small island in the gulf of Engia, near the N.E. point of the island of Engia.

TURLUPINADE, a term used chiefly among the French for a low jest or witticism. The occasion of the name is said to be derived from a famous comedian at Paris, called Turlupin; whose talent confined chiefly in raising a laugh by miserable puns and quibbles.

TURLUPINS, Turlupini, a denomination given to the brethren of the free spirit; whose external aspect and manners carried a very shocking air of lunacy and distraction. They called their sect the fraternity of the poor, and spread themselves over England and France. They are said by some to have had their name turlupines, quod ex tantum habitore loca, qua lapis esopstata erat. Thay attempted to settle themselves at Paris in 1372, but were a great part of them burnt, with their books; as is related by Gaglin and Du Tillet, in the life of Charles V.

TURMERIC, or Indian Saffron, in Botany. See Cur- cuma.

Turmeric, Curcuma, in the Materia Medica, a medi-
nal root, being the root of the curcuma longa of Linnaeus, used likewise by the dyers, to give a yellow colour.

It is externally greyish, and internally of a deep lively yellow or saffron colour, very hard, and not unlike, either in figure or size, to ginger.

It is brought chiefly from the East Indies, but it is common in the gardens of the Chinese, who use it as a fermentatory, and grows abundantly in Malacca, Java, and Balesa. In England it was first cultivated by Mr. P. Miller in 1759. It has been long officially known. That should be chosen which is big, new, refrinous, hard to break, and heavy.

Some people have mislakenly imagined, that there was a native red turmeric; their error was owing to this, that the yellow root, as it grows old, turns brown; and when pulverized, is reddish. It is much used by the dyers, &c. to dye their clothes. The Indians use it to dye their rice, and other foods, of a yellow colour: whence some call it Indian saffron.

Our dyers do not find that it gives fo ready a yellow as the luteola, or weld; nor can any of the mordants give it a sufficient degree of durability; common salt and ammoniacal muriate fix its colour fast, at the same time rendering it deeper; but it is admirable to brighten and heighten the red colours dyed with cochineal and vermilion; as scarlets, &c.

Turmeric has a slight aromatic, and not very agreeable smell; and a bitterish, slightly acrid, and somewhat warm taste. It readily gives out its active matter, both to aqueous and spirituous menstrua; communicating to the former its own deep yellow, and to the latter a fine yellowish-red tincture. Diluted with water, it yields a small quantity of a gold-coloured effential oil, of a moderately strong smell, and pungent taste: the remaining decoction, infusitated, leaves a bitterish, considerably saline mass. The impregnated extract from rectified spirit is moderately warm and bitter, and not a little nauseous. In the Eastern countries, this root, besides its use in colouring and seafoning their food, is much recommended as a medicine; being accounted one of the most effectual remedies in obstructions of the vificera and melenetery, which are there frequent; in uterine disorders, difficulties of urine, and affections of the kidneys. Among us it has also been employed by way of decoction, infusion, and powder as a depurative, leucon, astringent, and aperient; and efficaciously as one specific in the jaundice: the dose in subsance is from a ferialpe to a drachm; in decoction or infusion twice as much. It tinges the urine of a deep yellow colour. Lewis.

Although the use of this root has been highly commended, it is now very rarely employed. A plaster of turmeric, well bruised, top and roots, is thought to be good against the bite of the rattle-snake. See Phil. Trans. No. 479. p. 144.

Turmeric-Wafes, is the gum of the turmeric-root dissolved in water. The qualities and uses of it are much the same as those of the yellow-berry wath for water-painting; but it is a brighter and cooler yellow; for which purpose it should be dissolved in spirit of wine instead of water, by putting two ounces of proof-spirit, and one ounce of water, in a phial, with two drachms of powdered turmeric-root, shaking them well together, and letting them stand, with a repetition of the shaking, for three or four days.

Turmero, in Geography, a town of South America, in the government of Caraccas; 40 miles S.W. of Leon de Caraccas.

Turn, a town of Walachia, at the confluence of the Ailt and the Danube; 24 miles S. of Brancovan. Vol. XXXVI.

Turn is used for a circular motion; in which sense it coincides with revolution.

Turn, in a Clock or Watch-work, particularly denotes the revolution of a wheel or pinion.

In calculation, the number of turns which the pinion hath is obtained by common arithmetic; thus 5 60 (12, where the pinion, playing in a wheel of 60, moves round 12 times in one turn of the wheel. Now, by knowing the number of turns which any pinion hath in one turn of the wheel it works in, you may also find how many turns a wheel or pinion has at a greater distance; as the contrate-wheel, crown-wheel, &c. by multiplying together the quotients, and the number produced is the number of turns, as 5 35 (11 5 45 (9 in this example.

The first of these three numbers has 11 turns, the next 9, and the last 8. If you multiply 11 by 9, it produces 99; that is, in one turn of the wheel 55, there are 99 turns of the second pinion 5, or the wheel 40, which runs concentrical or on the same arbor with the second pinion 5. If you multiply 99 by the last quotient 8, it produces 792, which is the number of turns the third pinion 5 hath. See Clock-Work and Pinion.

Turn, in Mining, is a pit funk in some part of a drift. If the mine be deep, there are many of these turns one below another.

Turn-House. When a drift is driven across the country N. and S. to cut a lode, the miners make a right angle from their drift, and work on the lode itself; which, as it is in a contrary direction to their past drift, they call turning-house, in order to work on the course of the lode.

Turn, in the Manege, is a term commonly used in directing to change hands. See Change and Entier.

Turn, in the Sea Language. See Land Turn, Tack, and Turning.

Turn, or Tourn, is also used for the sheriffs court, kept twice a year in every hundred within his county, viz. a month after Easter, and within a month after Michaelmas.

From this court none are exempted but archbishops, bishops, earls, barons, religious men and women, and all such as have hundreds of their own to be kept.

It is a court of record in all things that pertain to it; and is also the king's feet through all the county, of which the sheriff is judge; this court being incident to his office. The attendance on it is called feeta regalis, or fait-royal.

It is called the sheriff's turn, because he takes a turn or circuit for this purpose through the shire, holding the fame in several places.

Turn in the Head, in Rural Economy, a disease in calves and young cattle, in which external objects would appear to turn round. The affection in this case seems to arise from some diffigated state of the brain, or parts about it.

In the cure, bleeding is advised, in proportion to the fize and strength of the animal; after which a powder, compose of camphor, valerian, nitre, and birthwort, in the quantity of a drachm of the firt to an ounce of each of the other ingredients, should be well powdered and mixed together, and then given at once in a pint of rofemey tea, repeating it as occasion may require.

By this means much advantage has been gained, it is said, in some infallences of this difeafe.

Turnado. See Tornado.

Turnagain Aim, in Geography, a branch of the north part of Cook's inlet, extending eall from Point Pef-ffion.
Tournament, or Tournament, a martial sport or exercise, which the ancient cavaliers used to perform, to shew their bravery and address.

The first tournaments were only contests on horseback, in which the cavaliers tilted at each other with canes in manner of lances; and were distinguished from jousts, which were courses or careers, accompanied with attacks and combats, with blunted lances and swords.

Others say it was a tournament when there was only one quadril or troop; and that where there were several to encounter each other, it was a joust; which fee. But it is certain that the two became confounded together in process of time; at least we find them so in authors.

The prince who published the tournament used to send a king at arms with a safe-conduct, and a fword, to all the princes, knights, &c. signifying that he intended a tournament and a clashing of swords, in the presence of ladies and damfels: which was the usual form of invitation.

The first engaged man against man, then troop against troop; and after the combat, the judges allotted the prize to the best cavalier, and the best friker of swords; who was, accordingly, conducted in pomp to the lady of the tournament; where, after thanking her very reverently, he saluted her, and likewise her two attendants.

The tournament made the principal diversion of the thirteenth and fourteenth centuries. Münster says, it was Henry the Fowler, duke of Saxony, and afterwards emperor, who died in 936, that first introduced them; but it appears from the Chronicle of Tours, that the true inventor of this famous sport, at least in France, was one Geoffrey, lord of Preuilly, about the year 1066.

It is difficult to fix the epocha of their institution, as many nations have laid claim to it. Richard relates, that at the interview of Charles the Bald, king of France, who succeeded to the throne in the year 946, and his brother Lewis of Germany, at Strasburg, the gentlemen of the retinue of the princes fought on horseback, to display their courage and skill.

Du-Cange says, that these sports were so peculiar to the French, that they were called confilitus Gallici, or French combats. To this purpose Matthew Paris, under the year 1179, says, "Henricus rex Anglorum junior mare tranfienis in confilitus Gallicis, et profuloribus exquisitis, triennium peregit, regiaue majeftate deponita, totus eft de rege tranfitus in militiam." In the Historia Byzantina tells us, that the Greeks and Latins borrowed the use of it from the Franks; and we find mention made of it in Cantaczenus, Gregorias, Befiarion, and others of the late Greek authors.

Initiatives of them occur among the English in the reign of king Stephen, about the year 1140; but they were not much in use till Richard's time, towards the year 1149. After which period these diversions were performed with extraordinary magnificence in the Tilt-yard, near St. James's, Smithfield, and other places. At last, however, they were found to be productive of bad effects, and the occasion of several fatal mishap; as in the infancy of Henry II. of France, and of the tilt exhibited at Chalons, which, from the numbers killed on both sides, was called the little war of Chalons. These and other inconveniences, resulting from these dangerous pastimes, gave the popes occasion to forbid them, and the princes of Europe gradually concurred in discouraging and suppressing them.

Budeus derives the word tournament from Trojana agmina; others from Trojamentum, quae ludus Troja. Menage deduces it from the Latin tornare, or the French tournier, because the combatants rode in rings and circles, and were obliged to make many turnings with their horses, as the laws of the game required.

M. Paris calls them in Latin hastiludia; Neubrigensis, meditations militares; others, gladiature; others, decusiones latici, &c.

It is natural, however, to conclude ex vi termini, that although the sport itself may owe its rise to the Trojan game, yet that its name is of French extraction, and not only given with great propriety, but seems to be a tacit agreement of its superior antiquity among that people, whose historians affect that it was first known in France. BERGER'S Art of Horsemanship, vol. i. p. 104, &c.

Pope Eugenius II. excommunicated those who went to tournaments, and forbade them burial in holy ground. King Henry II. of France died of a wound received at a tournament. One Chiaoux, who had affilied at a tournament under Charles VIII. said very wisely, "If it be in earnest, it is too little; if in jest, too much."

It is to the exercice of tournaments that we owe the first use of armories, of which the name blazonry, the form of the escutcheons, the colours, principal figures, the mantlings, labels, supporters, &c. are undeniable evidences.

In Germany it was an anciently a custom to hold a solemn tournament every three years, to serve as a proof of nobility. For the gentleman who had affilied at two was sufficiently blazoned and published; i.e. he was acknowledged noble, and bore two trumpets, by way of crée, on his tournament caque. Those who had not been in any tournaments had no arms, though they were gentlemen.

TURNAU, in Geography, a town of Bohemia, in the circle of Bohlem; 14 miles N.E. of Jung-Bunzel. N. lat. 53° 32'. E. long. 15° 11'.

TURNDORF, a town of Bavaria; 21 miles N.N.W. of Amberg.

TURNEBUS, Adrian, in Biography, a learned critic and scholar, was born at Andeli, in Normandy, in the year 1512, educated at Paris, and intimately acquainted with every branch of classical literature. After having been employed for some time in teaching the classics at Toulon, he became, in 1547, a professor of Greek at Paris, in which station he was very popular. He also superintended the royal press for Greek books, which he declined on being appointed professor-royal of Greek in 1555. In his manners, which were mild and condescending, meek and modest, he differed, as we regret to observe, from many eminent scholars; so that Henry Stephens pronounces this eulogy upon him,

"Hic placuit cunctis, quod fibi non placuit."

His fame spread through Italy, Spain, Germany, and England; from which several countries he was honored with many lucrative propostals, which he declined, though at home his income was fcanty. He closed his life at Paris in 1565, at the age of 53 years, and his remains were privately interred in the cemetery of poor scholars, at Montaigu-college. Catholics and Protestant, claiming him respectively as one of their own body, concurred in their testimonies to his learning and character. His works conftit of "Annotations upon Cicero, Varro, Thucydides, and Plato;" "Writings against Ramus;" "Translations from Aristotle, Theophrastus, Plutarch, Plato, and other Authors;' "Poemes, Latin and Greek;" "Treatises on particular Subjects;' and "Adversaria; or, Miscellaneous Remarks on Writers," which latter was printed at Paris in 1 vol. fol. 1580. Of his versions, Huet says, that they posseff every quality necessary for perfect transalations; as he understood Greek thoroughly, and turned it into elegant Latin, without deviating from his author, and his style was clear and agreeable. His works were

TURNEF, Island, in Geography, an island in the bay of Honduras, about 20 miles long, and 10 broad, abounding in cocoa-nut trees, and much frequented by fishermen. \( \text{N. lat. 17° 16'.} \) W. long. 89° 20'.

TURNEP, in Botany, &c. See BRASSICA and TURNIP.

TURNER, William, in Biography, one of the fathers of English botany as well as of the English Protestant church, was born at Morpeth in Northumberland, probably about the year 1520. He was educated at Pembroke college, Cambridge, under the patronage of sir Thomas Wentworth, and about the year 1538 had already distinguished himself for science and learning, being justly dissatisfied with the little real information he could obtain from those about him. Natural philosophy, medicine, and botany, chiefly engaged his attention at this time, but the great questions involving the vital interests of religious truth and liberty, having been stirred up, he devoted himself also to their examination, and, hazard the danger and obloquy incident, more or less, in every age and country, to the honest prosecution of such enquiries. Turner, like many others in England, at this period, united the characters of a physician and a divine. He became an itinerant preacher, of so zealous a character that the infamous bishop Gardiner threw him into prison; from whence he was, after a long time, released, we are not informed by what means, and became a voluntary exile from his native land. He resided on the continent with many other English refugees, principally at Cologne, and Bafle, till the death of Henry VIII. During this interval, Turner travelled into Switzerland and Italy, where he contracted a friendship with many distinguished botanists and physician, especially the great Conrad Gesner of Zurich, and professor Ghini of Bologna, the founder of the physic-garden, and of the botanical chair, in that university, and the preceptor of Casparinus and Anguillara. At Ferrara Turner received the degree of doctor of physic, which was confirmed to him at Oxford, when he returned to England on the accession of Edward VI. He was made physician to the Protector Somerset, and his ecclesiastical merits were still more amply rewarded, by a prebend of York, a canonry of Windsor, and the deanship of Wells. He had deferred this preferment by several publications in defence of Protestantism, which very caufe, however, obliged him to fly from the persecutions of the bloody Mary, during whose whole reign Dr. Turner remained abroad. The accession of Elizabeth restored him to his liberty and native soil, as well as to all his ecclesiastical benefits. The rest of his life was devoted to his clerical duties, and his botanical amusements; two pursuits which in many honours and good men have "gone very lovingly together," to their mutual advantage, and honor. He resided at Wells, and another at Kew, and appears to have divided his time between his deanship, and his residence in Cruchted Friars, London. Dr. Pulleyne thinks, from Turner's frequent mention of the plants of Purbeck, and Portland, that he had some intimate connections in Dorsetshire. This worthy man died July 7, 1568, apparently at no very advanced age, leaving several children. "His son Peter was educated to physic, travelled, and took degrees abroad; was incorporated doctor at Cambridge, and at Oxford, and died, aged 72, in 1614, but does not seem to have inherited his father's turn for botany." Turner's earliest botanical work is said to have been printed at Cologne in 1544, in octavo, under the title of História de natura herbarum, Jedediah, et nostre vallata. But this is mentioned by Bumaldis, or rather Ovidius Montalbanus, only, in his Bibliotheca Botanica, Segnière's edition, p. 18, without notice of any other publication of our author; nor does it appear to be known to English collectors, any more than the following. "Names of Herbes in Greek, Latin, English, Dutch, and French," printed at London, 1548, in 12mo., by the same writer.

The chief publication of Dr. Turner is his well-known Herbal, in small folio, black letter, with wooden cuts, of which the first part was originally printed at London in 1551, and is now, on account of its rarity, much valued by collectors. The second part appeared at Cologne in 1562, accompanied by a reproof of the first. In 1568 these first and second parts were reprinted at the same place, with a new title page, a dedication to queen Elizabeth, from which many of the above particulars of the author's life are taken, and the addition of a third part of the same work. To the whole are subjoined "A booke of the natures and properties as well of the bates in England as of other bates in Germany and Italy, as may necessary for all fuch persons that are either sickes or heal'd without the helpe of natural bates:" and "A moft excellent and perfecte homely apothecarye or homely phyfick booke, for all the grebes and defeases of the body, translated out of the Almaine speche into English, by Iohn Hollybusch." For this last saient production Turner is, perhaps, not responsible. The Herbal is arranged alphabetically, and is more original and practical, than the more popular and celebrated publications of Lyte, Gerarde, or even Parkinson. The object of the author was to determine the plants of the ancients, and to record their reputed virtues. But this is accomplished with more caution and discretion than are common to most of his contemporaries, and with far less dogmatical confidence than Fabius Columba subfrequently affirmed. The third part, dedicated to the company of surgeons, profiles more especially to treat of medical plants not known to the ancients. The author apologizes in these terms for its imperfections. "For surely being so much vexed with sickness, and occupied with preaching and the study of divinity and exercise of discipline, I have had but small leasure to write Herball." This dedication is dated "at Welles 1564." The wooden cuts of all the three parts of Turner's Herbal are taken from those of Tuchhis, and at first sight appear to be the very same blocks as those used in the octavo edition of the latter author, printed at Lyons, in 1595. A careful inspection however will easily detect minute differences; and we especially observe slight damages in Turner's figures, not occurring in this later impression, which decisively prove it to have been printed from more recent cuts. Haller gives our author credit for having first figured the true Microc, and the Rubus Cotinus; fec. part 24, 52 and 115. Under the former he describes various species of Medicago, distinguishing their different seed-sheels; and of the latter exhibits a sufficiently expressive delineation, with a correct, though brief, history.

Turner ranks moreover among our earliest British zoologicals. He published at Cologne, in 1544, an octavo of ten pages, entitled Avium praecipuarum, quarum apud Plinium et Aristotelen mentio est, historia. Conrad Gesner, to whose museon he repeatedly contributed, after his settlement in England, speaks of him as eminently deserving of praise in the department of ornithology; and Merret in his Pinax mentions the above little book, as great in authority, though small in bulk. Gesner has prefixed to the third volume of his own ponderous Historia Animalium, a letter of Dr. Turner's, dated Wissenburg, Nov. 1557, in which the various kinds
kinds of Flipes known in England, amounting to more than fifty, are briefly distinguished, with their Latin and English names. At the conclusion of the dedication of his Herbal to the queen he promises a book of the names and natures of Flipes that are within her majesty’s dominions, if he might have rest and quietness in his old age, and defence from his enemies, “which,” says he, “have more than thee eight years continually troubled me very much, and holden me from my book.” He speaks here also of nicknames, as an impediment to his labours. His work upon bathe is marked with the fame originality of thought, and practical observation, as his botanical and zoological writings. Turner wrote also on the “Wines commonly used in England,” and on the “Nature and Virtue of Treacle.” His numerous treatises on controversial divinity, published and unpublished, were chiefly in defence of the Reformation; but his most valuable undertaking of this kind we presume to have been his collaboration of the translation of the Bible, with Hebrew, Greek, and Latin copies, in consequence of which he found occasion to correct it in many places. How far his corrections were turned to advantage by the translators in James I.’s time, we are not informed.

Dr. Pulteney observes, that “he procured to be printed at Antwerp, a new and corrected edition of the Hierofia Gentis noflra. f. Angles, written by William of Newburgh, from a manuscript he found in the library of Wells;” but he complains of the printer, for omitting his preface as well as other communications. Turner translated several works from the Latin, particularly “The Comparison of the Old Learning and the new;” written by Urbanus Regius; printed at Southwark in 1537, 8vo.; and again in 1538 and 1548. We regret having never met with this book, as the subject promises much; and in the hands of Turner, or any man like him, who dared to think for himself, and whose judgment was regulated by prudence and learning, it could not but be valuable and instructive.—Turner’s Herbal.

Turner, William, a fellow student with Purcell and Dr. Tudway, among the second set of chapel-children under Dr. Blow, was sworn in gentleman of the royal chapel in 1669, as a counter-tenor singer, his voice fettling to that pitch; a circumstance which so seldom happens, naturally, that if it be cultivated, the possessor is sure of employment: and, in consequence of its utility, soon after his reception into the chapel royal, he was appointed vice-choral in the cathedral of St. Paul’s, and a lay-vicar of the collegiate church of St. Peter, Westminster. In 1666, he was admitted to the degree of doctor in music at Cambridge.

Dr. Turner arrived at the great age of eighty-eight, and dying in 1740, was buried in the cloister of Westminster Abbey, in the grave with his wife; who, being nearly of the same age, died but four days before him, after living together with great harmony of disposition, and felicity, near seventy years.

In many of our cathedral books there is an anthem, “I will always give thanks,” which is called the club-anthem, on account of its having been composed by three masters in conjunction; but not, as has been said, by Dr. Boyce and others, “as a memorial of the strict friendship that subsisted between them;” for, according to Dr. Tudway, who remembered the transaction, and records it with the anthem in the Mus. Collect. vol. iii. “the anthem was composed by order of Charles II. at a very short notice, on account of a victory at sea over the Dutch, the news of which arrived on Saturday, and the king willing to have the anthem performed the next day, and none of the masters choosing to undertake it, three of the children of the chapel, Humphrey, Blow, and Turner, performed the tale.”

There are two whole services, and several anthems, of Dr. Turner’s composition in Tudday’s collection, with an ode for the solemnity of St. Cecilia’s day, 1697, accompanied with violins and trumpets. To this there is a long symphony or overture, consisting of two movements, the second of which is in triple time, upon a ground, seemingly in imitation of Purcell, as the first movement is of Lulli. After this production, is inflected his anthem, “The King shall rejoice,” which is more in the style of a secular ode, than a composition for the church. The divisions, light and common in the last century, are now become extremely old-fashioned.

Gen. Ch. Col. Perianth inferior, double; the outermost of two combined, oblong, permanent leaves; inner of one leaf, funnel-shaped, deciduous; tube oblong, erect, cylin- drical, slightly angular; limb erect, in five deep lanceolate segments, the length of the tube. Cor. Petals five, invariably heart-shaped, pointed, flat, moderately spreading; claws narrow, inserted into the tube of the calyx. Stam. Filaments five, oval-shaped, shorter than the corolla, inserted into the tube of the calyx; anthers pointed, erect. Pfl. German superior, conical; styles three, thread-shaped, the length of the flanes; stigmas in many capsillary divisions. Peric. Capsule ovate, of one cell and three valves. Receptacles linear, attached lengthwise to the valves. Seeds numerous, oblong, obtuse, dotted, each furnished with an oblong, membranous, lateral tunic.

Eff. Ch. Outer calyx of two permanent leaves; inner funnel-shaped, five-cleft, deciduous. Petals five, inserted into the calyx. Stigmas many-cleft. Capsule superior, of one cell, and three valves. Seeds numerous, each with a lateral tunic.

Of this well-marked genus, which we presume to belong to Jaffret’s Tiliacea rather than to any other of his orders, Linneas has described but four species, to which Willde- now has added five from Aublet and Jacquin. We are en- cabled to furnish three new species from the Linneas herb. Aublet’s Piriqueta differs from the rest in having in five fylles, a point of no generic importance in the present case. All the species are found within the tropics, in South America, or the West Indies; none in the East Indies, nor in Europe. Their fylles are either shrubby or herbaceous. Leaves alternate, villos, simple, and mostly undivided, though crenate or serrated. Pubescence rather silky. Flowers yellow, falked, axillary, or occasionally raceme; their falks in some instances combined with those of the leaves. Outer calyx wanting in some of the species.

TURNERA.

β. T. umifolia; Mill. Illust. t. 14. (T. angustifolia; Curt. Mag. t. 281. T. fruticosa, folio longiore et mucronato; Mart. Cent. t. 49. f. 2. T. n. 1; Mill. Ic. 179. t. 266. Fig. curiosissimo folio, folio latiusculo vaficulatis trigonolis; Sloane Jam. v. 1. 202. t. 127. f. 4, 5.)

Flowers sejile on the footstalks. Leaves ovato-lanceolate, acute, coarsely serrated, with two glands at the base. Outer calyx ovato-lanceolate, notched.—Native of the red hills, and other places, in Jamaica; cultivated by Miller, and frequently seen in our flowers, especially the narrow-leaved variety, β, flowering from June to November. The calyx is bristly, but soft, or partly herbaceous, leaving a few years only, several feet high, with roundish, wavy, downy branches, leafy at the ends. *Leaves* ovate, or lanceolate, varying in length from two to three inches, and in breadth from half an inch to above an inch, unequally and bluntly serrated, strongly ribbed and veined, soft and downy on both sides, felted when bristly. Footstalks half an inch or an inch long, bearing two peltate glands near the top. Flowers large, bright yellow, short-lived, solitary, on the footstalks of few of the upper leaves, close to the leaf itself. *Outer calyx* of two ovato-lanceolate, strongly notched or serrated, permanent leaves, refembling the proper foliage; *inner tube*, bulbous, silky, yellowish, in five lanceolate, entire, deciduous segments, shorter than the corolla. We can scarcely think there is any specific difference between the broad and the narrow-leaved varieties. Millenow's β and γ are precisely the same plant. He, like Linnaeus, erroneously refers Sloane's *fynonym* to the broad-leaved variety, though Martyn had previously, like Miller, considered it as belonging to our β. His figure, in fact, represents that intermediate form of leaf which most usually occurs.

2. T. stipulata. Aawl-shaped Turnera.—Flowers sejile on the footstalks. Leaves ovate, acute, coarsely serrated, with two glands at the base. Outer calyx awl-shaped, entire.—Gathered in New Granada by Mutis, whose specimen was very inaccurately referred by Linneaus to *T. umifolia*. The leaves are ovate, not much above an inch in length, very downy and hoary, like the footstalks and branches. *Flowers* like-wise smaller than those of *umifolia*; their petals, in the dried specimen at leaf, nearly white, with a purple radiating spot on the disk. *Calyx* clothed with dense silky bristles; the leaves of the outer one very narrow, awl-shaped, channelled, and quite entire, affording a decisive specific character. *Capitule* the size of a pea, clothed with long silky bristles. The peltate glands, on the edge of the leaf itself, are very large and conspicuous in this species.

3. T. obtusifolia. Blunt-leaved Turnera.—Flowers sejile on the footstalks. Leaves obovate, obtuse, coarsely cre- nate, with two glands at the base. Outer calyx linear-lanceolate, flat, entire.—Native of Brazil. Communicated to the younger Linneaus by Thouin, probably from Com- meron's collection. This is very clearly distinguishable from the two former by the broad, obtuse leaves, finely hairy, one inch and a half long, and one inch in breadth; wedge-shaped at the base; broadly and bluntly crenate. The leaves of *calyx* are broader, flatter, and rather shorter, than in the leaf, measuring about half an inch. *Capitule* twice as large as in that species, coriaceous, densely covered with rigid bristles. *Seeds* club-shaped, beautifully reticulated, with intermediate depressions; their tunic nearly of their own length.

4. T. Pumilia. Nettle-leaved Dwarf Turnera. Linn. Sp. Pl. 387. Am. Acad. v. 5. 395. Wild. n. 2. Att. n. 2. Swartz Obs. 116. (Pumilia n. 1; Browne Jam. 188. Chamaecristus urticae folio, flore luteo; Sloane Jam. v. 1. 202. t. 127. f. 6.)—*Flowers* sejile on the footstalks. Leaves lanceolate, deeply serrated, without glands. Outer calyx linear, minute, hairy.—Native of dry sandy fields in Jamaica, flowering late in the year. *Swartz*. Rost annual, fibrous. *Stem* herbaceous, from one to three inches, or more, in height, simple or branched, erect or decumbent, round, hairy, leafy. *Leaves* about an inch long, so deeply serrated as to be almost pinnatifid, clothed with long-scattered hairs, but deftite of glands at the base. Flowers small, yellow, seldom expanded, solitary, sejile, at the base of each upper leaf, on its hairy footstalk. *Outer calyx* of two small, linear, upright leaves; *inner* in five linear hairy segments, pressed close to the corolla. *Petals* convolute, with long orange-coloured claws. *Seeds* roundish, compressed, corrugated. *Swartz*. The Linnzean specimen, from Browne, has no flowers, nor is it easy to say whence Linneaus took his account of the inflorescence, which, nevertheless, is confirmed by *Swartz*.

5. T. fibuloides. Sida-leaved Turnera. Linn. Mant. s. 32. Wild. n. 4.—Flower-stalks axillary. Outer calyx linear. Leaves nearly sejile, obovate-wedge-shaped, sharply serrated, downy and hoary on both sides, without glands.—Gathered in Brazil by Father Panzani, whose specimen was sent by Arduin to Linneaus. The calyx is bristly at the base, four or five inches high, erect, simple, round, leafy, clothed with hoary down, and long, soft, tanw hair. *Leaves* rather more than an inch long, covered on both sides with dense, entangled, somewhat hairy, soft, hoary pubescence; strongly and acutely serrated upwards; entire at the base, and tapering down into a very short hairy footstalk. *Flowers* axillary, nearly sejile, tanw, their *flalks* and *calyx* downy, and clothed with long, yellow, shining hairs. The specific character of Linneaus, *peduncula bifida*, seems to allude to the two linear or awl-shaped leaves of the outer calyx.

6. T. fistulifera. Brantley-limbed Turnera.—Flower-stalks axillary, partly combined with the footstalk. Outer calyx linear. Leaves obovate-wedge-shaped, deeply serrated or pinnatifid, very hairy on both sides, without glands.—Gathered by Commeron at Monte Video and Buenos Ayres. The size of the leaf. *Stem* bristly at the base, throwing up a few simple, wavy, nearly upright, hairy, leafy branches, from three to five inches high. *Leaves* more flaked, and much more deeply cut, than in *T. fibuloides*, being sometimes sharply pinnatifid; they are scarcely at all hoary or downy, but covered with long, silky, yellow hairs, such as are extremely copious on the branches, flalks, calyx, and capitule. *The flowers* are said to be of a tanw red. *Their calyx* is very long and linear. *Their flalks*, as far as we can judge, are connected, for about half their length, with the adjoining footstalks. This species is certainly near akin to the last, and the segments of its *leaves* are evidently variable. *We cannot, without spoiling our only specimen of *T. fistulifera*, determine whether its *flower-stalk* be really separate from the footstalk or not. What Linneaus in the *Manualia* terms *branched*, are what we have all along called, after his own example in the *Sida*, *Vegetabilibus*, *an outer calyx*; which is this part perhaps, as professor *Swartz* says, entirely wanting in the next species, though we must allow it to be there till more like *branched*.

ground in Jamaica. Sent by M. Richard, in 1774, to Kew
garden, where it flowered in the flore, from June to Oc-
tober. The root is annual, long and simple. Stems one or
more, subdivided, erect, from fix to twelve inches high,
round, leafy, hairy. Leaves on short flasks, spreading,
bluntly toothed or serrated, about an inch and half
long, clothed on both sides with minute flarly hairs; paler
below. Flowers small, yellow, on long slender hairy flarks.
swelling upwards, bent or jointed about the middle, where
are sometimes to be seen two minute bracteas, hardly to
be deemed an outer Ca/e. The proper calyx is hairy, in
two lancelate acute segments. Capsule somewhat hairy, pale.
Seeds buff-coloured, curved, elegantly impressed with
numerous rows of minute dots.

Vind. v. 3. 49. t. 94. Willd. n. 8. Ait. n. 4.—Flower-
flaks in a terminal cluster; the lower ones axillary, many
times longer than the footflaks. Outer calyx wanting.
Leaves ovate, bluntly serrated, downy.—The native
country of this species is not known, but we have little doubt
of its West Indian origin. Jacquin received its seeds with
the name of T. ciffoides, under which a species lies in the
Linnean herbarium. M. Thouin sent feeds to Kew in
1789, and we have what seems a garden specimen from him.
The root is annual. Herb much larger than the ciffoides
with a very hairy, slightly branched, stem. Leaves broadish-
oveate, two inches long, unequally serrated, clothed with
extremely soft, flary, depressed hairs. Footflaks brily,
almost an inch in length. Flowers small, dull or tawny
yellow, on very long and slender hairy flaks. Calyx hairy.
Capsule slightly hairy, each of its valves splitting into two.
Seeds pale, rough with minute points between the deprefed
dots.—The calyx in this and the lafl species does not anfwer
well to the idea of the genus, the tube, though prefent and
permanent, being very fhort, nor are there any traces of the
two outer leaves. Perhaps the latter had been left un the
generic character, which is sufficiently marked without
them.

291. t. 114. Willd. n. 9.—Flowerflaks in a terminal cluf-
ner, smooth. Outer calyx linear, entire, naked. Leaves
linear, smooth, ftrightly ferrated, with two glands at the
base.—Gathered by Aublet in the marfy meadows of Ti-
moctou in Guiana, flowering in April. Root fibrous, pro-
bably annual. Herb fflender, with a fmall, angular,
flabbly, branched stem. Leaves nearly ferially, two inches
long, much less deeply ferrated in Aublet’s specimens
than in his figure. Flowers small, yellow, on short ffloned partial flaks, collected, very few together,
into a fufier. Outer calyx permanent, glandular at the
bottom, rather longer than the inner, whose segments are, as
in all the species we have hitherto decribed, deciduous, the
permanent base being fhort, like that of T. racemofa. Ca-
sule very fmoth, of three undivided valves.

t. 113. f. 1. Willd. n. 3.—Flowerflaks axillary, very fhort.
Outer calyx linear-lanceolate, toothed, somewhat brilly.
Leaves nearly linear, toothed, very fmoth, almost fcelifer.
—Found by Aublet, in the moft mofly clefts of rocks
about the great water-falls of Sincmar in Guiana, flowering
in November. A rigid, fnder, branched shurb, about a
yard high, whose ftems are more or less covered with Jun-
germania. Leaves crowded about the ends of the branches,
nearly fcelifer, an inch and a half long, very narrow, taper-
ing at each end, slightly revolute, and arnifhed with half-
length teeth, and by no means ferrated, as in Aublet’s plate, from
which Wildenow took his specific definition. Flowers
small, yellow, nearly fcelifer, solitary in the cottoms of two
or three of the uppermoit leaves. Outer calyx toothed, or
rather ferrated, longer than the inner, whose segments are
lanceolate and entire; both are slightly clothed with clofe,
fiiky, white hairs. Petals oblong, jagged at the end.

290. t. 113. f. 2. Willd. n. 5.—Flowerflaks axillary, very
fhort. Outer calyx linear-lanceolate, toothed, somewhat
brilly. Leaves lanceolate, ferrated, very fmoth, almost fcelifer.—Oberved by Aublet, on the rocky banks of the
Sinimari river, above the great fall, flowering in December.
The natives call this shrub, as well as the former, Nepator-
from. The prefent appears to us a variety of the lafl, dif-
tering only in its more luxuriant growth, being feven or
eight feet high, with larger more dilated leaves, whose
length is two or three inches, their breadth above half an
inch, their veins far more numerous, and their margins
rather ferrated than toothed. These differences may arife
from a more favourable situation, or more fertile foil. In
the flowers or infor nfence there feems no difference what-
ever.

12. T. rubifca. Wrinkled Tornera. Willd. n. 6. (Piri-
queta villosa; Aul. Guian. 298. t. 117. Burcardia;
Schreb. Gen. 296, adopted from Scopoli; expunged at
T. 828, and placed in T. 578.)—Flowerflaks axillary,
many times longer than the footflaks. Outer calyx want-
ing. Leaves ovate, unequally cleft, wrinkled, downy.
Styles five.—Native of the fandy fhe-shores of Cayenne
and Guiana, flowering and bearing feed almost all the
year round. The root is annual. Stem fcelifer, about two
feet high, branched, leafy, villous. Leaves on very short flarks,
bluntifh, two or three inches long, rather epiftical, veiny,
rugged, clothed with reddifh hairs. Flowers fmall, yellow,
on long, fnder, hairy flaks. Capsule very like that of
T. racemofa, n. 8, which this species fo nearly refeembles in
many refpects, that, were it not for the five fyles, and the
more cleft and rugged leaves, we fhould be difposed to
unite them. We place this at the end, for future examina-
tion, not having seen a fpecimen to determine the quefion.

Tornera, in Gardening, compoffes a plant of the woody,
flowering, exotifc kind, for the flowe, the fpecies of which
cultivated is the elm-leaved Tornera (T. ulmifolia); which
has a shrubby stem, rifting eight or ten feet in height, and
a bright yellow flowcr. It is found in the Weft Indies.

There is a variety with narrow leaves, which alfo fimes
with a fhrubby stem, about eight or ten feet high, with
branches lefs fnder and fliff than in the broad-leaved fort:
the leaves narrow-lanceolate, hairy, near three inches long,
and about three quarters of an inch broad, terminating in
acute points, obtufely ferrate on their edges, and flanding
upon very fhort footflaks; when rubbed they emit a dif-
agreeable odour: the flowers are of a pale yellow: the
petals large and oval, with the tails or claws twifled, and
joining: they are not fo large or half fo bright a yellow as
in the true elm-leaved fort. This is a native of Jamaica.

Culture.—Both of these plants are eafily raised from feed,
which fould be fown in the fpring, in pots, and plunged
in the bark-bed, or any other hot-bed, under glaffes; and
when the plants are come up two or three inches in height,
they fhould be planted separately in small pots, plunging
them in the bark-bed of the flowe, to forward them a little
in growth: they may afterwards be placed in any part of
the flowe, and be managed as other flowe exotifc plants.

They are alfo capable of being increafed by cuttings, planted
in pots or in hot beds, and forwarded to the height of eight
or ten feet. They afford a good variety among flowe-plants, but they
are feldom of long duration, as they moftly go off in the

1
TUR

course of two or three years, being therefore rather of a biennial nature.

TUNESOLE, or Tunsoles, in Botany. See HELIOTRIPUM, and CROTON TINCTORIUM.

Some have translated tunsole by the English word sun-flower, which has led many to suppose that the great yellow sun-flower, which we keep in gardens, was the plant that afforded the tunsole colour: but this is a mistake; and it is to be observed, that the true tunsole plant, or heliophyllum tricoccum, is very common in the fields of France, especially about Montpellier, and in Germany, but does not grow wild with us in England.

The juice of the berries of the tunsole, rubbed upon paper or cloth, at first appears of a fresh lovely green, but presently changes into a kind of blueish purple. It is said that the common blue paper receives its colour from this juice. The fame cloth, afterwards wet in water, and wrung out, will turn the water into a claret colour; and it is to be observed, that the rags of cloth tinctured by this juice, and turned red by acids, are usually called tunsole in the druggists' shops, and employed for colouring wines and other liquors. M. Nisoffe, of the French Academy of Sciences, says, that the colouring juice is obtained, not from the berries, but from the tops of the plant, gathered in August, ground in mills, and then comminuted to the pres. The juice is exposed to the sun for an hour; the rags dipt in it, dried in the sun moistened by the vapour which arises during the baking of quicklime with urine, then dried again in the sun, and dipt again in the juice. The Dutch and others are said to prepare these rags and tunsole in the masts from other ingredients, of which archil is a principal one. Boyle's Works abr. vol. ii. p. 19.

Neumann's Chem. by Lewis, p. 433.

The Dutch process for making the blue called tunsole is as follows: Lichen, archil, or in case this last cannot be obtained, the greater moss of the oak, is dried, cleaned, and pulverized in a mill, resembing the oil-mill, and then dipt into a burea wire sieve, the interstices of which do not exceed one millimetre in width (\(\frac{1}{24}\) of an inch). The sifted powder is then thrown into a trough, and mixed with an alkali called vedas, which is nothing else but the cendres gravelles in powder. The proportion is one part by weight of the alkali, to two parts of the pulverized vegetable. This mixture is moistened with a small quantity of human urine; the urine of other animals does not contain a sufficient quantity of ammoniac. The mixture ferments, and is kept moist by successive additions of urine. As soon as the materials have become red, they are transferred into another trough, where they are again moistened with urine, and filled to renew the fermentation. Some days afterwards, the pate acquires a blue colour, in which it is carefully mixed with one-third of excellent potash well powdered; and with this new mixture certain trays are filled, which are one metre (39½ inches) deep, and eight decimetres (34½ inches) wide. When the fermentation which takes place for the third time has given the pate a considerably deep blue colour, chalk or powdered marble is added, and the whole is well and perfectly mixed. This last addition is made, not to improve the quality of the blue, but to add weight. It is merely an affair of profit. The blue thus prepared is put into iron moulds 32 centimetres long and 22 square at the end (14 inch by 8½ths of an inch). The moulded pieces are then placed upon deal planks, in well-aired lofts, to dry; after which they are packed in cakes for sale.

The Hollanders have a secret of this process; and in order to mislead, they have published, that the blue was

made with rags coloured by the plant tunsole; whence it has obtained its appellation. The English writers have used this denomination: but the dry-fellers, or dealers in drugs, distinguishing thee paltilles by the name of limus. We may derive much profit by carrying this discovery into practice.

The principal use of this plant is in dyeing: in order to which, the juice is infusified and prepared with calx and urine, into blue cakes; which are used also with flaxen, instead of smalt.

The lixivium of this plant in lime-water and urine, or in the volatile spirit of wine, turns marble blue. See Colouring of Marble.

TUNNESS, in Geography, a cape on the eait coast of the island of Hov. N. lat. 58° 47'. W. long. 3° 10'.

TURNETUM, in our old Law Books, a duty paid to the sheriff for holding his turn, or county-court.

TURNHOUT, in Geography, a town of France, in the department of the Two Nethes, built in the year 1272, by Henry IV. duke of Brabant. In the year 1545, after the peace of Munfler, Philip IV. gave it to his sister Mary, queen of Hungary, to enjoy during her life. In the year 1649, after the peace of Munfler, Philip IV. gave it to princes Amalia, widow of Frederick Henry of Nassau, from whom it came to the house of Orange. The quarter of Turnhout comprehends fifteen villages; 25 miles S.S.W. of Bois-le-Duc.

TURNING, in the Mechanical Arts, is the operation of shaping wood, metal, or other hard substances, into a round or oval figure, by the aid of a machine called a lathe; which see.

In turning, the work or substance to be operated upon is placed in the lathe, and made to revolve with a circular motion about a fixed right line as an axis of motion; and the exterior surface is worked to its intended figure by means of some kind of edged tool, which is presented to it and held fast down upon a fixed reft. The protuberant parts of the work, by its rotary motion, are carried against the cutting edge, and cut off, so as to reduce every part of the outside surface, to an equal distance from the axis of motion, and of course it will be of a circular figure.

The articles which admit of being turned to give them their figure, are all such as combine the three following properties: 1. That they may be supposed to have an imaginary right line or axis passing centrically through the whole length of the piece; 2. That all the sections which can be made by planes perpendicular to such axis shall be circular; and 3. That the centre of all such circles shall coincide with the axis or centre line.

It should be observed, that a piece of work may have two or more centre lines in different parts or in different directions; but it must in that case be formed or turned at two or more successive operations, because what can be done at once fixing in the lathe, must come within the above definition.

The work may be turned hollow, so as to make a cavity within side; or work may be turned on the outside, to give form to the external surface; and frequently work is turned both without and within; but in either case, the above definitions will apply.

Diodorus Siculus says, the inventor of the art of turning was a nephew of Daedalus, named Talus; and that the reputation which he acquired by this invention excited the jealousy of Daedalus, and induced him to put Talus secretly to death. Pliny ascribes it to Theodore of Samos, and mentions one Thericles, who rendered himself very famous by his dexterity in managing the lathe. With this instru-
ment, it is fuid, the ancients turned all forts and kinds of vases, many of which they enriched with figures and ornaments in baffle relievo. Thus Virgil says:

"Lenta quibus torno facili superadita vitis."

The Greek and Latin authors make frequent mention of the lathe, and Cicero calls the workmen who used it, *oficia*. It was a proverb among the ancients, to say a thing was formed in the lathe, to express its delicacy and juftnefs.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for many ornaments, both within and without highly finifhed houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not only to embellish their instruments, but also to give them the necessary dimensions and precision: in short, it is an art absolutely necessary to the mechanic, the goldsmith, the watchmaker, the joiner, the fmith, and others.

As the operation of turning is to be performed by the aid of the lathe, the structure of that machine is the first thing to be considered. In our article Lathe, we have given a definition of the most perfect kind of lathe, made in iron, with a triangular bar; and in the article Rose-Engine, we have described a curious lathe for ornamental turning; but it is to be obferved, that a much more fimple machine will answer all the common purpofes of turning.

The essential properties of a lathe for outside work are, firft, that it shall have two points which will firmly fupport the work at each end, by penetrating into the ends of the work, and, at the fame time, allow it to turn freely round upon the points: there muft be a reft or fupport to hold the tool upon, and also fome means of turning the work round upon the points. A lathe to turn hollow or inside work will not admit of a point of fupport at each end of the piece, and therefore the work is firmly fixed to the extremity of a fpinde, which is called a mandrel; when the mandrel is turned round, the work revolves with it, and the tool can be applied at the end of the work, to excavate or turn it hollow withinfide, or to turn it on the outside, as required.

Lathes are made in a great variety of forms, and put in motion by different means: they are called centre lathes, where the work is fupported at both ends; and mandrel, fpinde, or chuck lathes, when the work is fixed at the projecting extremity of a fpinde.

From the different methods of putting them in motion, they are called pole lathes, and hand-wheel lathes, or foot-wheel lathes. For very powerful works, lathes are turned by horfes, fteam-engines, or water-wheels.

The lathes used by wood-turners are generally made of wood, in a fimple form, and are called bed lathes: the fame kind will serve for the common turning of iron or fteel, but the bed work in metal is always done in iron lathes, which are fometimes made with a triangular bar, and are called bar lathes, (fuch an one is defcribed in the article Lathe); fmall ones, for the ufe of watch-makers, are called turn-benches, and turns; but there is, in fact, no proper definition between thefe and the centre lathes, except in regard to size, and that they are made of iron and brass instead of wood.

The centre lathe is the moft fimple of all others. Two beams of wood are fixed horizontally upon legs, like a bench, and form what is called the bed. The two beams are fixed togeth'er, parallel to each other, and at a small distance afunder, fo as to leave a space or narrow groove between them, nearly the whole length of the bed. This groove is to receive the tenons at the lower ends of the *puppets*, which are short pofts riling perpendicularly from the bed, and firmly fixed thereto by means of crofs wedges, put through the tenons beneath the bed; for the tenons are of fufficient length to de fend quite through the groove in the bed, and project beneath fufficiently to receive the crofs wedges, which being driven in, draw the bases of the puppets or pofts so firmly down upon the surface of the bed, that they will fland firmly erect upon it; or by withdrawing the wedges, the puppets become loofe, and can be fixed in another part of the bed, in order that the diftance between the two puppets may be made to conform with the length of the piece of work to be turned. One of the puppets has a pin or *pike* of irôn fixed into it, and the other one has at the fame level the centre *ferron*, working through a nut fenten in the puppet: both the crew and pike have fharp points made of fteel, hardened and tempered, that they may not wear away. They muft be exactly oppofite, and in a line with each other. The piece of work, fuppofe for inftance it is a roller of wood, is fupported by its ends between the points of the pike and the ferron, that it may turn round freely. The *red* for the fupport of the tool is a rail or bar, extending from one puppet to the other; it lies in hooks, projecting from the faces of the puppets.

The work is put in motion by means of the *treadle*, which is worked by the turner’s foot; a *fling* or catgut is fenten to the treadle, and paffing two or three turns round the work, it is fenten to the end of an elfatic *pole*, fixed to the ceiling over the turner’s head.

The workman stands before his lathe, having one of his feet on the treadle to give it motion; he places a sharp *gouge* or *chiffel* on the ref, and approaches the edge of it gently to the piece of work; then prefing the treadle down by his foot, the *fling* turns the work round, and the chiffel or gouge being held ffirm upon the ref, and fo as to touch the wood, it will cut it to a circular form. When he has brought the treadle to the ground, he relaffes the weight of his foot, and the elfacity of the pole draws up the treadle, turning the work back again; during which retrograde motion, he withdraws the chiffel from the work, as it would not cut in this direction, though it might impede the motion of the wood, and would injure the edge of the tool. He muft perform his work gradually, without leaving ridges; and when he meets with a knot in the wood, he muft go on still more gently, otherwise he would be in danger both of flitting his work and breaking the edge of his tool. For finishing light work, a bow, fuch as is used for shooting arrows, is fenten by its middle over the lathe; the *fling* is then tied to the middle of the bow-tring, in lieu of the pole, and acts in the fame manner.

The common centre lathe is a very imperfect machine, when worked in this manner; yet its fimplicity is a great recommendation, especially among country workmen, who ufe it to make various forts of common articles of houfehold furniture in foft wood, as ftool and table legs, flair-cafe rails, &c.

In centre lathes, the work is sometimes put in motion by means of a large wheel, turned by one or more labourers; the wheel should be heavy, that its momentum may be fufficient to overcome any moderate obfacle in the work; and the frame in which it is mounted muft be of fufficient weight to fland fleady, and not be liable to move, by the exertions of the man turning it. An endles fline is ufed, to communicate the motion of the wheel to the work; it paffes round a groove in the circumference of the wheel, and after crossing, like a figure of 8, goes round a small pulley, fixed upon the work. By this means, when the great wheel is turned, it gives a rapid rotatory motion to the matter to be turned, and with a much greater power than can be obtained from the treadle, with the additional advantage of the work turning always the
the same way round, so that the turner has no need to take his tool off the work.

The centre lathe will turn any kind of work which will admit of being supported at both ends; and it is used by millwrights and iron-founders, for turning mill-shafts, axles, rollers, and other iron-work. For such purposes, the lathe must be made exceedingly strong, and with nuts and screws to fasten the paddlets down upon the bed, instead of wedges; the reft must be made in iron, with the requisite adjustments for placing it close to the work, at that part where it is required to be turned. To put the work in motion, the centre pin or point in one of the paddlets is made to project considerably, and has a pulley fitted upon it, so that it can turn freely round upon the pin by means of an endless band or ftrap, which communicates the motion from a great wheel. In these large lathes for iron-work, the wheel is commonly turned by horsies, or by a water-mill or steam-engine.

From the pulley a pin projects in a direction parallel to the centre pin, and a piece of iron, called a driver, is screwed or clamped fast upon the end of the piece of work, fo as to project from it sufficiently either by a piece of line which is fastened into the pulley: by this means, the motion of the pulley is communicated to the work. The tools employed for turning iron and other metals are different from those used for wood, as we shall afterwards describe.

The spindle or mandrel lathe will turn hollow or internal work, and is equally well adapted to turn centre work as the centre lathe. In Plate Turning, fig. 1, we have given a representation of one of these, which is on a very good construction, made by Mefiers, Holtzapfel and Deyerlien; it is put in motion by the foot, fo that the turner has both his hands at liberty to direct the tools. A A are upright legs, to support the bed B, which consists of two pieces or bars of cast-iron, put together, and leaving a small crack between them: C D is a cast-iron frame, which is fastened down upon the bed B, and supports the spindle or mandrel a b: E is the back puppet, which is used to support one end of a piece of work, as is shown in the figure at G, when the other end is fixed to the end of the mandrel, and turned round by it: the back puppet, E, has a cylindrical pin accurately fitted into it at the upper part, and the end of the pin is formed to a sharp conical point, proper to penetrate and support the end of the work: this point is called the back centre. A screw e is tapped into the puppet, fo as to press on the opposite end of the pin, and force it towards the work; and there is likewise a clamp screw, E, at the top, to bind or fasten the pin into its socket. The back puppet is fastened down upon the bed, by means of a tenon entering into the groove, through the bed B, and a screw defends from the tenon quite through the bed, and projects beneath it: upon this screw a nut g is tapped, and by turning it, the shoulder of the puppet E is drawn down firmly upon the bed; but when the nut is loosened, the puppet is drawn along the bed to place it at any required distance from the end of the spindle, according to the length of the piece of work G. It is necessary that the point of the back centre should in all cases be precisely in the centre line of the axis of motion of the spindle a b; and for this purpose, the bed must be made very straight, and flat on the upper surface; the groove through it should also be perfectly straight and parallel, and the tenon at the lower end of the back puppet must be exactly fitted to the groove: the frame of the mandrel must be so fixed on the bed, that the centre line of the mandrel will be exactly parallel to the bed, and to the groove in the bed.

Mandrels are mounted in different ways, but they are always made of steel at the parts where they are supported in the collars, which collars should be also made of steel, and hardened, so as to have little friction. The neck of a mandrel must be very accurately fitted into the collar, fo as to have no shake or looseness, at the same time that it can turn round quite freely.

The neck at one end projects beyond the collar, and the projecting part is formed to a screw, for the purpose of fixing the work to it. A variety of pieces, called chucks, are fitted upon this screw, and each chuck is adapted to hold a different piece of work: the chucks screw up against a shoulder on the end of the mandrel, and by the motion of turning round in the direction in which the lathe works, the chuck screws itself fast on against the shoulder; but if the lathe is stopped, and the chuck is turned in the opposite direction, it will unscrew and come off, and a different chuck may be put on. In some lathes, the neck of the mandrel is perforated, and cut with a line, with a female fcrew adapted to receive a male fcrew on the chuck: the effect is just the same as the above defcribed. The opposite end of the mandrel to that on which the chucks are screwed, must be supported either by a piece of line which is fastened into the pulley; or the mandrel is made with a point at one end; and the other end, which has the screw to fix the work to it, is formed with a neck, proper to run in the collar, and with a shoulder on the neck, to flop the neck from going through the collar. The mandrel represented in the drawing has a neck and collar at each end, for a purpose which will be explained. When the mandrel is made with a pointed end, the point must be received in the end of a screw tapped through the part D of the frame of the mandrel, just in the place of the end a of the mandrel. By turning this screw, the mandrel can be adjusted to run very correctly in length; and to prevent the screw from turning back when the lathe is in motion, a nut is placed on the screw, beyond the part d: this caufes such a pressure upon the threads of the screw, that it is in no danger of turning back, as it would otherwise do with rough work. The mandrel, by this means, runs very steadily and accurately in its bearings, and it is plain that any piece of work, which is firmly attached to the end of it by means of the screw before mentioned, may be turned by a tool held over the reft, in the same manner as if it were mounted between centres, but with the advantage that it be turned at the end, to make hollow work when required.

The mandrel is turned round by a band of catgut paffing round the pulley b, and also round the large foot-wheel H, which is made of cast-iron, and fixed on the end of the axis I. This axis is bent in the middle, as in the figure, to form a crank, which crank is united, by an iron link K, to the treadle L, on which the workman preffes his foot. This treadle is affixed by three rails to an axis M, on which the treadle moves. The wheel H is of considerable weight in the rim, and being fixed fast on the axis I, turns round with it: the momentum acquired by the wheel is the power that continues to turn the work while the crank and treadle are rising, and consequently while the workman exerts no power upon them.

When the crank has paffed the vertical position, and begins to descend, the workman preffes his foot upon the treadle, to give the wheel a sufficient impetus to continue its motion until it arrives at the same position again. The length of the iron link K, which connects the crank with the treads, must be such, that when the crank is at the lowest position, the board L of the treads, to which the link is hooked, fhould hang about two or three inches from the floor. To put the lathe in motion, the turner gives the wheel a small turn with his hands, till the crank rife to the highest, and

Vol. XXXVI.
paffles a little beyond it; then by a quick tread he brings the crank down again, putting the wheel in motion with a velocity that will carry it several revolutions: he must observe to begin his next tread just when the crank paffles the highest point, and then it will continue running the same way with a tolerable regular motion, if he be punctual in the periods of his treads. The foot-wheel, by means of the band, caufes the mandrel to revolve very rapidly, fo that it will perform its work very quick, and the workman muft acquire a habit of standing steady before his work, that he may not give his whole body a motion when his foot rides and falls with the tread.

The head of this lathe is fixed on the bed of the lathe by its foot, which is divided in the manner of a fork, to receive a clamp-bolt: this bolt paffles down through the lathe-bed, and fallens the reft at any place along the bed, by a nut & beneath. The groove in the foot is for the purpofe of allowing the reft to be moved to and from the centre of the work, to adjust it to the diameter of the work which is turning. The height of the reft is a matter of some importance in turning, and in some work it should be fixed higher than others; therefore the piece upon which the tool is laid, is made with a flank of the form of the letter T. This flank is a round pin, and is received into a socket in the foot of the reft, and can be held at any height by a clamp-screw. As the socket and flank are cylindrical, the edge of the T of the reft can be placed inclined to the axis of the work when turning cones, or other similar work, though the fame purpofe may be accomplished by the screw, which holds the foot of the reft down to the bed of the lathe, admitting the fork to fland in an oblique direction across the bed.

The wood-turner employs gouges of all fizes, and chiffels of different forms: the gouges are used in the firft infance to rough out and form the wood, as they cut very rapidly, because they can take a very strong chip, and the angles will not fllick in, as would be the cafe with the chiffels. The latter are used to smooth the work, and to reduce it exactly to shape and fize.

The blade of the turning-gouge is formed nearly half round to an edge, and the two extreme ends of this edge are a little flopped off, in the manner of an apple-fcoop, that the middle part of the edge may cut away the prominetites of the work; and it has no corners, which would catch and get falt in the rough wood. The hollow part is whetten upon a piece of Turkey-flone, made with a convex edge, for the purpofe; the outside is whetten upon a common flat Turkey-flone, taking care to turn the gouge round, that all parts of the convex edge may fuccellively be sharpened. In turning, the blade of the gouge muft be held confiderably inclined, by deprefling the handle (fee fig. 42.), fo that the bevil, or outside of the edge of the gouge, may come very nearly in the tangent to the circumference of the work, and the cutting edge be above the level of the centre. The turner holds the tool down firmly upon the reft, keeping it steady, by placing the long handle under his arm.

The turner's chiffels are mostly ground with a bevil on both the flat fides, fo that either fide may be indifferently applied to the work: they are ground up and sharpened on the oil-flone to a keen edge. In fome chiffels, the line of the edge is inclined to the direction of the blade, instead of being perpendicularly across it, as in the chiffels used by carpenters; in others, the edge is rounded to a femicircle, instead of being a straight line; and others are made with angular points, like spears. It is dificult to decribe the proper ufe of each particular tool, as the turner muft employ one or other, according to the particular part of the work which is to be executed. In using the chiffel, the reft is raised confiderably above the centre of the work, fo as to be nearly on a level with the top of it (fee fig. 43.), and the line of the cutting edge muft fland oblique to the axis of the cylinder, fo as to prevent either angle of the chiffel from running into the work. It is neccessary to traverse the chiffel gradually along the work, but not too far, otherwife it will leave a roughnefs on the surface.

The turning-tools should be fixed in long handles, and the turner holds them firmly down upon the reft, steadying them by placing the end of the handle under his arm.

The turner should be provided with a grindstone, and an oil or Turkey-flone to sharpen his tools; and he muft have callipers and gauges to ascerten the dimensions of his work. In order to fix the work in the lathe, he muft have a great affortment of chuckes. The chuckes for wood-turning are blocks of wood, each having a fcrew, by which it can be attached to the mandrel. The end of the chuck being turned true, and the shoulder of the screw upon the mandrel being also turned true, the chuck fixes fo tight to the fpindle, that it becomes as it were one piece with it. Most of the wood chuckes are bored out like a box, and the work is jambed into the cavity. There are other chuckes, which are only flat round boards, and the work is cemented or frewed againft them; but the generalty of chuckes are cylindrical blocks, with a cylindrical or conical hole turned in the end, like a box, into which the piece of wood to be turned is driven falt, fo as to be turned round with the mandrel.

The chuckes are generally hooped with iron, to prevent them from splitting. When centre-work is to be turned in a mandrel lathe, a chuck muft be frewed on the end of the mandrel, which terminates in a fharp conical point.

The lathe should be fixed in a place very well lighted; it should be immovable, and neither too high nor too low.

The puppets should neither be fo low as to oblige the workman to floop in order to fee his work properly, nor fo high, that the little chips, which he is continually cutting off, should come into his eyes.

The piece of wood to be turned fould be rounded, before it is put in the lathe, either with a small hatchet made for the purpofe, or with a plane or rafl, fixing it in a vice, and faving it down till it is every where almoft of an equal thicknefs, leaving it a little bigger than it is intended to be when finifhed off. Before putting it in the lathe, it is alfo neccessary to find the true centres of its two end facefces, fo that they shall be exactly opposite to each other, in order that, when the centre points of the puppets are applied to them, and the piece is put in motion, no one fide may project out more from the centre line than another. To find these two centres, lay the piece of wood to be turned upon a plank, open a pair of compafes to almoft half the thicknefs of the piece, lay one of the legs on the plank, and let the point of the other mark on one of the ends of the piece when laid flat on the plane with the plank, like a roller, from which plank the point of the compafes stands up at a given height above the plane on which the piece lies. Deferibe four marks or arcs on that end at equal diatances from each other round the circumference of the end, by laying the piece fuccellively on four different fides, which arcs intersecting one another, the-point within the interfections will be the centre of the end. In the fame manner, the centre of the other end muft be found.

After finding the two centres, make a small hole at each of them, into which infert the centre points of the back centre and the mandrel, and frew up the back centre; to fix the
the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

This is the manner of fixing the work when it is to be turned between centres; but if it is required to be hollowed out, the back puppet is removed, and the work must be fixed in a chuck at the extremity of the mandrel. For this purpose, a chuck is selected which has a hole in it nearly the size of the piece of wood, the diameter of which being taken in the callipers (fig. 35.), the chuck is screwed to the mandrel: the reft is fixed in a convenient position, and the hole in the chuck turned out by a proper tool to the size measured by the callipers: the hole should be rather conical, and the wood, being rapped to the fame figure, is driven in half by a hammer. By turning the mandrel slowly round, it will be seen if the wood is fixed straight in a line with the mandrel, and if not, a blow or two of the hammer, properly directed, will reftify it.

If the piece of wood is not very long, the chuck will be sufficient to hold it firm whilst it is turned; but if it is not, then a small central hole must be made in the extreme end, and into that point of the chuck, that part which must be inserted to steady the work, until the rough part of the turning is done, and then it may be removed; but it is much more convenient to turn without the back centre, and therefore the turner fits the chuck to the wood with care, so that it will fix fast in the chuck.

The work being thus chucked, or fixed in the lathe, the reft is set, so that its edge is close to that part of the work which is required to be turned, and the top of the reft being raised considerably above the level of the centre of the work, it is there ferewed fast.

The turner now puts the lathe in motion by treading with his foot, and takes a gouge, of a proper size, in his right-hand, and holds it by the handle a little inclined, keeping the back of the hand lowermost: he grasps the blade of the tool with his left-hand, the back of which is to be turned upwards, and he holds it as near the end as possible on the front side of the reft; then leaning the gouge on the reft, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference: see fig. 42. This is the best position for cutting, and the tool must be held very firmly, to prevent the edge being depressed by the motion of the work, for if it does, it will take hold too deep, and tear the work. The gouge is applied first to one end of the work, and gradually advanced to the other, turning the work true all the way, and reducing it till the callipers (fig. 36.) determine it to be near the intended diameter.

The chiflel is next employed to smooth the cylinder: its handle is held in the right-hand, whilst the left grasps the blade, and keeps it steady upon the reft, holding the edge a little inclined over the work, as in fig. 41; so that one side of the flat part of the blade lies on the reft, and the other side is elevated, that the point of the blade, and consequently the line of the edge, is not horizontal, but inclined thereto, so that one corner of the edge of the chiflel is elevated above the work: then the bottom of the edge of the chiflel, or near the bottom, cuts away a shaving from the work, and this is the only way in which it will cut; for if the edge of the chiflel is held parallel to the axis of the cylinder, it acts parallel to the length of the grain of the wood, scraping away the fibres, one by one, without cutting, and leaves a very rough surface. In the same manner, the narrow chiflels, formers, and other instruments, are to be used according to the work which is to be done, taking care that the wood be cut equally, and that the instrument be not pulled suddenly forwards, or sometimes more strongly than at others; and taking care also that the instrument does not follow the work, but that it be kept firm on the reft, without yielding. The chiflel and chiffe] are the instruments by far the most frequently used, and the most necessary in this art. Soft woods are almost entirely turned by them.

To make the end of the work exactly flat, the thin side of the chiflel is laid upon the reft, so that the plane of the edge may lie exactly upright. The hand is depressed, that the lower corner of the edge may lie against the work, and cut a deep circle into it, near the end, and being steadily advanced, cut to the centre, separating a thin round chip, and leaving the end quite flat. The cutting corner of the chiflel must be directed exactly perpendicular to the length of the work, in advancing it, otherwise the end will be either concave or convex, and care must be taken to keep the plane of the edge truly upright, and hold it very firm, for there is danger of the work drawing the chiflel into the end of it, with a deep spiral cut, like a screw, and tearing the work out of the chuck.

A cylinder of wood being formed by the process, we have just described, if it is required to turn it hollow within-forwards, the reft is fixed opposite the end of it, with the edge of the reft perpendicular to the length: then a sharp-pointed tool is used, to bore such a hollow in the end as will form the required cavity, using the inside callipers (fig. 35.) to determine the size of it. The file-tool, which is made with a cutting edge on the side, like a knife, may be used, if it is required to make the bottom of the cavity square; or a hooked tool, with the cutting edge at the end of the hook, may be employed to enlarge the inside to the proper size: the gauge (fig. 34.) is used to determine the depth to which it is to be turned.

This is the process for turning soft woods, which are generally of a fibrous texture: but hard woods, ivory, and bone, are turned with different tools. The points or cutting edges of some such tools are represented in figs. 23. and 24; they are bevelled only on one side, and the angle of the edges is obtuse. The rounded-pointed tool, and the sharp angular-pointed tool, are those employed for firft roughing out the work, and by them a number of contiguous grooves are cut in the wood, until its grain is broken and divided, and the irregularities reduced; then an edged tool can remove the remainder: but as the edged tools will only cut or scrape off thin shavings, they are not used when the work is to be reduced to size, but only to finish it. The manner of applying the tools to the work is shewn in fig. 39. and is nearly the same as for turning brass, or other soft metal: the upper surface of the tool is directed to the centre of the work, the intention being to scrape away shavings in hard wood, and in soft to cut chips, as at figs. 41. and 42. The graver (fig. 40.) is a very useful tool for hard wood: the manner of using it, as well as other tools, will be described when we come to speak of turning in metal.

After the work is completely turned, it is next to be polished, and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear-tree, hazel, maple, &c. ought to be polished with shank-skin, or Dutch rubbies. There are different species of sharks, some of which have a greyish, others a reddish skin. Shark’s skin is always better when it has been used; at firft, it is too rough for fine polishing.

The Dutch ruff is the equineum hyemale: it grows in moist places, among mountains, and is a native of Scotland. The oldest plants are the boll. Before using them, they should be moistened a little, otherwise they break in pieces almost directly, and render it exceedingly difficult to polish with them: they are particularly proper for smoothing the
hard woods, as box, lignum vitae, ebon}', and chalk, finely pounded and put upon leather, or a linen cloth a little moistened with this: the piece is rubbed as it turns round in the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipped in water. To polish metals very finely, the workmen make use of a particular kind of earth called tripoli, and afterwards of putty, or calc of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces of tin or pewter, and then the which is rubbed into them and mixed with. The and silver are polished with a burnisher, and that kind of red stone called blood-flour. Iron and steel may also be polished with putty, putting it dry into shamoy-skin.

All kinds of articles in wood are turned in the above manner; but many contrivances are necessary to mount different things in the lathe.

The small figures in the plate represent various chucks, which are occasionally employed, and which are adapted for turning different kinds of work.

**Figs. 2. and 3.** exhibit a small wood chuck, which is adapted to be screwed to the mandrel at a, a hole being perforated in the centre of it, at b, into which a small piece of wood or ivory is to be inserted, in order to turn it. To hold the work fast in this chuck, it is divided at the end b by two saw-kers, at right angles to each other, as shewn in fig. 3, so as to separate the end into four segments, which admit of expanding or closing; a hoop or ferrule is fitted on the outside of the chuck, which part is made tapering, so that forcing the ferrule farther on, will close the four segments together, and bind the work, which is turned: this will hold the work. This is a very convenient chuck for holding small pieces of ivory, and particularly for the purpose of polishing.

**Figs. 12. and 13.** exhibit a similar chuck, made in brads, for more delicate work; it is only divided into two segments.

**Fig. 4.** is a brads box, to screw to the mandrel, and hold a wood chuck, such as we have before explained. Wood chucks are usually made to screw on the mandrel by means of a hole in the chuck, which is cut with a female screw within. The objection to this mode is, that the threads of the screw on the wood wear away by continual use. In fig. 4, a brads female screw, a, is cut to fit the screw of the mandrel, and at the other end, b, is a box, allo cut with a screw within, into which the wood block or chuck is screwed, as shewn by the dotted lines, so as not to come out without great force: by this means, the fitting of the chucks to the mandrel is not with a wooden screw, as in general, but with a brads one, which will not be liable to get out of the truth, but will always screw up to the same shoulder. The lathe should have at least two dozen of these wood chucks, with cavities of different sizes, and some of them looped with iron at the outer end, to prevent them splitting. The brads box is a great security against splitting.

**Fig. 5.** is a very useful arbor for turning wheels, collets, or any other flat piece of work that will admit of having a small hole in the centre of it. A brads screw-chuck, a, is fitted to the mandrel, and a female pin, b, is fixed into it, and projects an inch or more: the pin is turned true, and the work is fitted fast upon it, either by turning the pin to the size, or by broaching the hole in the work; and to prevent the work from slipping round upon the pin, it is pinched fast up against the flat surface of the chuck, as shewn by the dotted lines, so as not to come out without great force: by this means, the work will be held fast, and will be carried round by the chuck, so as to be turned by the application of proper tools upon the reft. These kinds of arbors should be of all sizes, to fit the holes in different wheels, &c.

**Fig. 10.** is a brads chuck, which is very useful for holding small pieces of brads work; it screws to the mandrel at the end a; the hollow part, b b, has fix screws tapped through it, and pointing to the centre, as shewn in fig. 11. By screwing in these screws, their points will pinch upon any piece of work which is put into the chuck, as shewn at d d, and hold it firm. The screws being regulated, of adjusting the work d to a true centre with the line of the mandrel.

**Figs. 16. and 17.** are views of chucks having similar properties to the preceding: a (fig. 16.) is the end which is screwed to the mandrel; b b is a circle of brads, having a mortise or opening across the centre of it, as in fig. 17; into this opening two brads dies are fitted, and screws d d, are placed behind them, to approach them together: the screws come through the outside of the chuck, and have square heads, which are to be turned by means of a key. The adjacent surfaces of the two dies are hollowed, so that they will embrace a piece of wire or other similar substance which is put between them, and the dies may be cut like a file, to hold it fast. By means of the two opposite screws d d, the work may be adjusted to the centre line of the mandrel.

**Figs. 20. and 21.** are a table-chuck, proper for holding wheels or flat plates by the circumference, while the centre parts are turned: a is the screw to fix it to the mandrel; b b, a large circular plate, turned perfectly flat on the front surface. In this plate are grooves, pointing from the centre to the circumference, as shewn in fig. 21: the grooves are adapted to receive clamp-pieces, d d, d d, by means of which the wheel or other work is bound fast against the flat surface of the chuck. The grooves admit the clamps d d, to be placed at any distance from the centre, according to the size of the work, and to place them at those parts where it will be most convenient to apply them.

The form of these clamps is shewn more particularly in fig. 22: f are slides of metal, which are fitted to the grooves in the chuck; and the grooves are dove-tailed, so that these slides can be put into the grooves at the back of the chuck, but will not draw through the grooves into the front. Screws are tapped into the slides, and draw the clamps, b, against the face of the chuck, and hold fast the work, which is placed beneath their claws. The clamps, b, have shanks projecting from them at right angles, which pass through the grooves, and keep the clamp from turning round to one side.

**Figs. 35. and 36.** represent the callipers used by turners to take the measure of their work: they are made of two curved pieces of steel-plate, united together by a joint. When they are opened, as in fig. 36, the dimensions of a round piece of work may be found by measuring between their points, as shewn by the dotted circle; but if the points are closed together, as in fig. 35, so that they pass each other, then the callipers are adapted for measuring the diameter of internal cavities, by the distances of their points from each other.

Several other kinds of callipers are used by turners, but these are the most convenient, as they serve equally well for inside and outside dimensions. Some callipers are made double, like a pair of scissors; and the points at one end are for inside measures, while the others are for outside measures; and the distances of all the points from the joint being exactly the same, the inside measure of any hollow work being...
being taken by one end of the calipers, the opposite end will be readily opened to the requisite dimensions for a solid to fill the hollow.

Fig. 34. is a gauge for measuring the depth of hollow work. A is a ruler, through which is a socket to receive another ruler B; and a clamp-screw is fitted through the side of the socket, to hold the ruler, B, fast in the socket. The edge of the ruler, A, is applied to the end of the work, and the other ruler is then shifted through its socket, until the end of B touches the bottom of the cavity; and in this state, the clamp-screw being fastened, the gauge may be applied to the piece of work in the lathe, to ascertain if the cavity is turned out to the required depth.

Fig. 6. is a chuck for turning wood when it is a long piece, which will admit of being supported at both ends, or between centres, as it is called. The chuck has a screw within the part a, to fix to the mandrel, and the other end is of steel, with a pin b in the centre; and on each side of the pin is a sharp edge c, like a chisel, the line of the edge pointing to the centre of the pin. When a piece of wood is mounted between the points of this centre pin and of the back centre, as we have before described, if the back centre screw is turned, it will force the piece of work against the mandrel and the pin b, and the edges c will penetrate into the opposite end of the wood; in this case, the motion of the mandrel and chuck a will be communicated to the wood, to turn it round. The centre pin b is made to project beyond the edges c, and by this means the work may be removed from the lathe, and put in again if required, because the centre pin will enter again into the fame hole in the end of the work, and restore the work to its original position.

Fig. 7. is a chuck for the fame purpose, but it is made with a flat circle of brass, and three pins, c, are fixed in it instead of the edges c, c. This kind of chuck is shown in use in fig. 1, to turn a pillar for a balustrade.

When a piece of metal work is to be turned between centres, the edges or points of the lathe chucks cannot be made to penetrate the end of the piece, and therefore a small chuck, b, (figs. 14 and 15.) is screwed to the mandrel: in the end of this chuck, at b, is a hole, which is made square withinside, and the work has a square filed at one end to fit the hole. The other end of the work is supported by the back centre, a small hole being made in the end to receive its point; or if the end of the work is sharp-pointed, the back centre pin is drawn out of its socket, and turned end for end: the end of the pin opposite to the point has a small centre hole for the reception of such pointed work. Iron and steel work may be turned very conveniently by means of a square, but not very accurately; and after the work has been turned out of the lathe, and the square cut off, if it be required to turn the work again in the lathe, it is very difficult to find the true centre.

All works requiring great accuracy, as arbors, screws, axles, spindles, &c. are turned between centre points, thus: a chuck (fig. 8.) is screwed to the mandrel by the screw in the part a, a steel centre point b being formed at the end of it. The point is turned very truly, to be exactly in the centre line of the mandrel. The work is mounted between this point and the point of the back centre; and to communicate the motion of the mandrel to the work, a driver (fig. 9.) is screwed fast on that end of the work nearest the chuck. The driver is an iron ring, with a screw d tapped through one side of it, to pinch the work so fast as to prevent the driver flipping round upon the work; and on the side opposite to the projecting pin, e.

The chuck (fig. 8.) has a fixed claw e fitted through it, and fastened by a screw: the edge of the claw is bent at a parallel to the direction of the mandrel, so that the end of it will catch the tail f of the driver, and turn it round, together with the work on which the driver is fixed.

The form of the chuck fits in and out of the socket, through the chuck, in order to remove the claw e to greater or less distance from the centre point b, and adapt the chuck to operate upon different sized drivers, for delicate or large work. This is the most accurate method of turning iron work in a mandrel lathe, because the centre points at the ends of the piece are preferred. When one end of the work is finished, the driver may be shifted to the other end. Such work may at any time be mounted again upon its original centre points, in any kind of lathe, to turn wheels, collets, &c. which may be fitted upon it.

The form of the driver is shown in fig. 30. In order to make it fit different sizes, the sides of the ring opposite to the screw d is made angular, and the point of the screw forces the work into the angular part.

This driver may be fixed on either end of the work, whilst the other end is turning; but when it is necessary to fix the driver on that part of the work which is finished, the end of the screw d is apt to pinch and bruise it; it is therefore proper to interpose a piece of iron between the point of the screw and the work. But it is better to use the driver shown in fig. 31: it is composed of two bars of iron, united by two screws passing through one bar and tapped into the other: both bars are somewhat hollowed out in the middle, that they may encompass the work. If this should be found to injure the work, a piece of sheet-lead wrapped round it before the driver is put on will prevent it from damaging the work; and if the screws of the driver are drawn very tight, it will carry the work about with sufficient force to bear turning.

When a piece of iron or fixed work is to be turned, the centre points at the ends must be found with great precision before it is turned, because it is difficult to cut away great protuberances in metal. The centres are first found by the compasses, and marks are lightly punched in the ends by a conical-pointed punch. The workman now places the work in the lathe, between the points of the mandrel and that of the back centre, but without fixing any driver on the work; he then fences up the centres, so as to hold the work just tight enough to prevent its falling down. In this state, by turning it round with one hand, while he holds a piece of chalk against it with the other, he ascertains whether it is pitched nearly concentric on the points; and if it varies much at any one point, he turns back the screw to take out the work, and punches new centre points, or alters the old ones, taking care to move them nearer to that side which appeared to project farthest in revolving, and was of course marked by the chalk.

When he has, by repeated trials, found the true centre, he fences up the centre point so hard, that it may effectually mark the end of the work, by forcing the points to the bottom of the marks punched; then taking the work out of the lathe, he drills holes in the ends, at the places which the centre points have marked, and to such a depth, that the points of the lathe will not reach the bottom. When the work is again returned into the lathe, it will run very nearly concentric, and the driver being screwed fast on either end of the work, as is most convenient, the work will be turned round by the chuck projecting from the chuck. The work is now ready for turning, which is done by different tools, and applied in a very different manner from the chisels and gouges for turning wood. Figs. 37. to 40. are different examples of the manner of turning metals: a tool applied in the manner of fig. 39. operates very well upon
upon brass and bell-metal. The cutting edge should be ground nearly to the angle which is there represented, and the upper side should be directed nearly to the centre of the piece; the edge will then scrape away shavings from the metal. The tool has some tendency to retreat backwards from the work, and must be held firmly thereto. The edges of tools, applied as shown in fig. 39, may be formed to any of the shapes shown in figs. 23 and 24, the angle of the cutting edge being in all cases nearly the same.

The graver (fig. 40) is an extremely useful tool, and fit for roughing any metal or hard wood: it is a square bar of steel, cut off obliquely, and the greatest obliquity of the cutting plane is in the direction from one angle of the square to the opposite angle. This produces a prominent point on one of the angles, which point is applied to the work in the manner shown in fig. 40, and cuts off continuous shavings instead of scrapings: this is owing to the direction of its edge, which is disposed obliquely to the motion with which the work meets the edge in its rotation. The turner should be provided with gravers of all dimensions.

Fig. 37, is the action of what is called a heel tool for turning wrought iron or copper; the edge of this is applied nearly in a tangent to the work, on the same principle as the chisel is applied to cut wood. The heel of the tool is placed upon the reft, and being just opposite to the edge on which the pressure or drift of the work lies, the tool cannot escape from its work, although the pressure upon it is very great, so much so, that it would be impossible to keep the tool to its work, if it were held upon the reft, as in the case of the chisel, merely by the lateral friction on the reft. The handle of the heel tool is long, and is held inclined upwards, so that the workman can rest the end of it on his shoulder, whilst he holds it very firmly down on his shoulder and on the reft with both hands. This firm position is very necessary, because the heel tool is liable to draw deep into the work, and take away too large a chip. This tool will cut away thicker chips than any other, being what the workmen term a greedy tool. The requisite height of the reft, to make the edge of the tool a tangent to the proper point, is a matter of importance, and requires the attention of the workman, who can only learn the management of this tool by experience. It is not well adapted for finishing work with accuracy, but is very expeditious in roughing out wrought iron: it generates so much heat in working, that it is necessary to keep it constantly wet; and in large lathes, a constant stream of water is made to fall on the edge at the place where it is cutting. The graver and all other tools work wrought iron and steel to the greatest advantage when wetted.

Fig. 39, is the tool used for turning cast-iron; this substance must be scraped away, and it is plain from the figure, that the cutting edge is presented very nearly in the same manner, with respect to the work, as in fig. 39; but from the hardness of cast-iron, it requires a very considerable force to press the edge against the work, and it would be impracticable to hold it up effectually on the plan of fig. 39; hence the tool in fig. 38, is bent at the end, and is lodged over the edge of the reft, in the manner of a lever; the handle is pressed down at the extremity, and lifts up the edge against the work with very great force. The workman must bear on the handle of this tool with the requisite pressure; and in large work, such as cannon and mill-shafts, he usually feats himself upon the end of the tool, which is made very long in the handle.

Different substances require different velocities of motion to cut with the greatest advantage. Wood can fearfully be made to move too quick; and it is always preferable to take a very thin chip, and move as quick as possible; than to move slowly, and compensate for the loss of time by cutting deep. Brasses and bell-metal may be moved very quick, but not with half the velocity of wood. wrought iron and copper must be turned more slowly, and the tool must be kept wet. Steel should go rather lower than wrought iron, for it is liable to have hard veins in it, which the workmen call pins: these will be cut through if the work moves too slowly, but with a quick motion they will destroy the edge of the tool: this makes some workmen think that the pins are actually formed, or that they become hard during the operation of turning, if too great a velocity is used. Cast-iron must move very slowly, indeed it can fearfully turn too slowly, and the tool applied as at fig. 38 will cut a thick chip.

To obtain these different degrees of velocity, the foot-wheel of the lathe fig. 1, is made with several grooves of different diameters, and the mandrel pulley $b$ has also different sizes. A band can be applied upon any of these grooves at pleasure, and the workman finds by experience what velocity is best for different kinds of work.

The most experienced workmen prefer a centre lathe to a mandrel lathe, when they have to turn accurate iron-work, which will admit of being poised between centres; and it is obvious, that the revolving motion of the centre point at the end of the mandrel is of no use; and if the point should be the leaf out of the centre line, or if the mandrel has any shake in its collar, the work would not be turned truly. But in a centre lathe, where narrow work is fixed immovably, or, as the workmen say, with dead centres, this cannot happen; and if the work is screwed up tight between the centres, so that there is no shake, the centre points at the ends of the work must be precisely in the centre line of the work.

The manner of giving motion to a piece of work in the centre lathe is, as we have before described, by a loose pulley fitted on the centre pin, and from this pulley a pin projects in a direction parallel to the centre line, so that it comes exactly in the place of the claw (fig. 8), and turns the driver round when the pulley is put in motion by the band, either from a foot-wheel or hand-wheel.

When the mandrel lathe is used for centre work, the centre of the chuck must be turned very exactly, so that it does not vary in the leaf from the same position when it turns round; and in all cafes, the mandrel must be fitted with the most scrupulous accuracy into its collar, so that there will be no shake; for unless this is the case, the lathe will not turn chuck-work with any accuracy.

Meffrs. Holtzapfel and Deyerlien make very excellent lathes on the plan represented in fig. 76. The bed and the puppets are made of cast-iron, and very correctly fitted, such lathes possess great strength: some of them are fitted up, as in the figure, with a pattern screw at the end of the mandrel, for the convenience of cutting screws on work. For this purpose, the mandrel is fitted in a collar at each end, and the necks are cylindrical, so as to admit of the mandrel moving endways at the same time that it turns round. On the extreme end of the mandrel, beyond the collar $D$, a pattern screw is fixed, which has the defiance of its threads corresponding with the screw that is destined to be cut upon the work, which is fixed in the lathe by a chuck: a piece of brafs, $n$, is provided, which is cut with threads adapted to the pattern screw, and which can, by turning a screw, be drawn up against the pattern screw, so as to work in its threads; and in this state the mandrel, at the same time that it turns round, will move endways in its collars with a screwing motion; and in consequence, a pointed tool being presented to the work, and held fast on the reft, will cut a spiral groove or screw upon its circumference. This contrivance is more fully
fully explained in the article Rose-Engine. It is the most
convenient method of all others for cutting screws, and very
accurate, if the pattern screws which are fixed on the mandrel
are correctly cut. For all purposes of wood turning, it is
undoubtedly the best method, and far preferable to the
common one of cutting screws flying, as it is called, that is,
by means of the tools 32 and 33, which are applied to
the work, and moved along endways at the same time
that the work turns round, so that they cut a spiral. (See
Rose-Engine.) The rapidity and accuracy with which some
workmen cut screws in this way exceed belief; but it is
only by long experience that this habit can be acquired, and
for those who have not had such experience, some mechanical
help is necessary. The objections made by accurate work-
men to the flying or screw mandrel are, that the necks
must be cylindrical, it cannot be kept so perfectly fitted in
its collars as the common mandrels, which have a point at
the extremity, and the neck at the other end is made slightly
conical, so that it can always be screwed up to fit in the
collar. Messrs. Holtzpafts mandrels are made of har-
dened steel at the necks, and the collars are also hard;
they are accurately fitted, and have no shake when new.
From the hardness of the materials, they will wear a long
time before they get any looseness.

Mr. Mauldlay has the most complete set of tools for all
kinds of mechanical works at his manufactory, and is particu-
larly well provided with turning apparatus. All his
lathes are made with triangular bars, such as is described in
our article LATHES, and the mandrels are all formed with
conical necks and collars. The bar lathes are very accurate,
particularly when the slide-refl is applied to them, as there
described. The bed lathe may also have a slide-refl applied,
as is shown under Rose-Engine.

If a piece of metal, after being properly turned, is to be
bored hollow within, like a gun-barrel, the back puppet is
to be removed from the bed of the lathe, and another sub-
fitted in its place, having a hole or collar through it, into
which the neck or end of the iron is to be correctly fitted,
the other end of the iron being supported and turned round
by being fitted into a chuck at the end of the mandrel,
and eyle by means of the centre point at the end of the
mandrel, and with a driver, as in figs. 8. and 9. The reft is to be fet
opposite the end of the piece where it comes through the collar,
and drills or borers are to be applied, similar to those used by
locksmiths in boring keys, beginning with a small one and
afterwards using larger ones, until the hole is made as wide
and deep as necessary. The borers must be held very firm
on the reft, otherwise there is danger of not holding the hole
straight. The boter should be withdrawn from time to
time, to oil it and clean the hole. As it is difficult to make a
hole quite round or concentric with the outside by means of
borers alone, it is necessary to have also a turning tool con-
derably smaller than the hole, one of the sides of which is
sharp, very well tempered, and a little hollow in the middle.
This instrument being fixed in a long handle, is to be intro-
duced into the hollow, and applied with steady hands to the
inner surface of the hole, and it will entirely remove every
inequality that may have been there before its application.
The collar puppet is only refitted to, when the piece which
is to be bored is of considerable length; for if it is short, it will
be held sufficiently fast in the chuck, without the necessity
of supporting the extreme end.

A collar puppet is sometimes necessary in turning centre
work when the work is long, and so slender, that it bends or
saggs by the fires of the tools: the collar is then applied
to support the work at the part where it is weakest and
bends most.

Turning of elliptical or oval Work, such as Picture-frames,
Snuff-boxes, &c.—This is performed in the same lathe,
and with the same tools, as the circular work; but the lathe
is provided with a chuck, which causes the work to traverse
in a very curious manner, by a motion given to it in a direction
to and from the centre of the mandrel as it revolves; so that
a tool held up against the work will cut an elliptical figure
instead of a circle. Elliptical work has a very singular
appearance when in motion; for after the work has been
turned truly elliptical, every part of the circumference,
except the exact point where the tool was applied, appears
to vibrate, or be eccentric in a great degree, but that one point
of the circumference runs perfectly true and regular, the fame
as the whole circumference of a piece of circular work does.
The mode of action of this ingenious apparatus is rather diffi-
cult to describe, and it is first necessary to understand the prin-
ciple of its action. This is the same as the trammel or elliptic
compasses; see fig. 29. An octagonal or square board
A A, B B, has two grooves cut in its surface, which in-
tersect each other at right angles; this board is held down
upon the surface where the ellipse is to be described, with
the centre lines of the cross grooves coincident with the
two diameters of the intended ellipse, and of course their
intersection will be its centre. The curve D D is traced be-
yond the circumference of the board, by means of a pen or
pencil, which is fixed at F, to a radical bar or beam F G H;
this bar carries two other points or pins, G and H, which
are attached to flinders, inserted into the cross grooves of the
board, as shown in the figure: the flinders are fitted in truly,
so that each of them will have a motion in its respective
grooves; thus the flider of the pin H will move along A A,
and the flider of G, along the groove B B. By turning
about the beam F G H, the flinders go backwards and for-
wards in their cross grooves with a simultaneous motion; so
that when the beam has gone one-fourth way abont, one of
the flinders will have moved from the circumference of the board
A B, to the common centre of the cross grooves; and when
the beam has gone half round, the fame flinder will have pro-
ceeded the whole length of the cross, and arrived at the
opposite side of the circumference. The fame applies to the ot-
er flinder, and when one flinder is at the centre, the other
will always be at the circumference.

The pins F and G H can be fixed at any part of the
beam at pleasure, (though this is not fo represented in the
drawing,) for the purpose of setting the trammel to draw any
particular ellipse: thus, place the beam in the direction of
the line A A, then the pin G will be in the centre of the cross
groove, now fix F at such a distance from the centre, as
is equal to half the small diameter of the ellipse, and let H fo
far distant from G, as the difference of the two diameters;
consequently, from F to H will be equal to half the longest
diameter. Now, in turning the beam round from the direc-
tion A A, till it comes to the direction B B, the point G
will depart from the centre along B B, and H will approach it
along A A, till it gets to the centre. Then will the pencil
F be so much farther from the centre, as G is distant from
H, and the pin has in its circuit traced one-fourth of an
ellipse. The beam being turned quite round, will complete
the whole curve.

This apparatus may be applied to turning by some modi-
fication. Suppose the two cross grooves made in a round
board, as large again as that represented in the figure; then,
if the whole apparatus be inverted, and the beam F H held
fast in a vice, or otherwise, the board with the cross may be
traversed round upon the fixed flinders, in the same manner
as the beam could be traversed round upon the fixed board.
Suppose a tracing point is held to the back of the board,
exactly opposite to the place where the tracing point \( F \) is fixed to the beam, and held fast; it is evident that its point will trace the name ellipse on the back of the board, that was described on the surface which the board lay upon in the former instance: or a chisel being held fast in the fame spot, will cut the board elliptical when it is turned round; and the chisel being successively applied at different points along the line of the beam, a series of concentric ellipses may be drawn in the board, to make mouldings for picture-frames or other ornaments. If the distance of the two fixed pins \( G \) and \( H \), and the chisel \( F \), is altered, it will vary the proportion between the two diameters of the ellipse, in the fame manner as before described of the trammel.

The oval chuck is constructed in a different manner from this, though it preserves the same movements. It consists of three parts, the chuck, the slider, and the eccentric circle. The chuck \( e e f \) (fig. 27.) is attached to the mandrel by a screw-focket, cut in a piece \( j \), which projects from the centre of it behind; and hence the chuck turns round with the mandrel with a circular motion.

The chuck has a dove-tailed groove, formed in it at the front side, for the reception of a slider \( g \) \( h \), (fig. 26.) which traverses freely in the groove; the groove is formed, as the figure shews, by pieces \( i, j \), screwed to the chuck on each side. In the centre of the slider, in front, is a screw \( b \); see also the plan, fig. 25. The screw \( b \) projects from the slider, and by means of it, a wooden chuck may be screwed against the slider \( i \) and any work can be fixed in the chuck in the usual manner. The work so fixed, at the fame time that it turns round by the motion of the chuck, has a sliding motion across the centre, which motion being given according to a certain law, produces an elliptic motion. The sliding motion is given by the eccentric circle (fig. 28.); this is a ring of brafs, attached faft to the puppet of the lathe, clofe to the collar, in which the neck of the mandrel runs. The mandrel passes through the aperture \( i \); the ring has a flat plate, \( m \), to strengthen it, and forming two bends at the ends \( m, m \), which bends have screws tapped through them, and pointing exactly to each other: these screws are sharp at the points, and are inserted into small holes in each side of the puppet, as is shewn in the plan, fig. 25. at \( C \), the back of the plate \( m \) of the circle lying flat against the front of the puppet \( C \); by this means the circle is fixed faft; the two screws are horizontal, and both point to the centre of the mandrel \( j \); therefore, by screwing one screw in, and the other out, the whole circle may be moved sideways horizontally, so as to give it any required degree of eccentricity from the centre line of the mandrel, and it will be held stationary wherever it is placed.

Fig. 27. is a back view of the chuck, and shews two grooves made through it in the direction of the length of the slider; these admit the shanks of two pieces of steel \( n, n \), to pass through the chuck, and they are firmly attached to the slider \( g \), by a screw for each in front of the slider, as shewn in fig. 26. The two infae edges of the pieces \( n, n \), are exactly parallel to each other, and the distance between them is exactly equal to the diameter of the outside of the ring 28, which ring is included between them, when the chuck is screwed to the mandrel \( b \), and the circle fixed to the puppet \( C \), as shewn in fig. 25.

Suppose then the circle is let concentric with the mandrel; if the mandrel is turned round, it will caufe the chuck \( e \), and slider \( g \), together with the work attached to the slider by the screw \( b \), to revolve. The work will now run in a circle, and turn circular work as usual, because the slider is guided by means of its claws \( n, n \), which embrace the circle, and will keep the same position in its groove in the chuck during all the parts of a revolution, because the circle is concentric with the mandrel.

To fet the chuck for an ellipse, place the point of a tool opposite the work, at such a distance from the centre of the work, that it will describe a circle of a diameter equal to the breadth or smallest diameter of the ellipse intended to be turned. This is best done by fixing the tool in the slider.

Now turn about the mandrel, till the slider \( g \) comes horizontal, and set the circle 28 eccentric from the mandrel by its screws \( m, m \); it will of course move the slider \( g \) in the groove of the chuck, and also the work will move with it to a greater distance from the centre, because the two pieces \( n, n \), at the back of the slider include the circle between them. The quantity of eccentricity given to the ring, must be equal to the difference between the two diameters of the required ellipse, so that the work shall move, or throw out a sufficient distance, to bring the point of the tool as much beyond the circle first described, as the length of the ellipse exceeds the breadth. The point of the tool will now be at one end of the longest diameter, and here we will commence to trace the curve all round. In turning the mandrel round till the slider comes vertical, it must return in its groove to the place it first occupied. This is the centre; because the eccentric circle which guides the slider is not eccentric in a vertical direction, though it is in the horizontal. In this motion, the point of the tool has cut or described one quadrant of an ellipse, but it is gradually approached to the centre by a quantity equal to the eccentricity of the circle. By continuing to turn the mandrel round farther, the circle will caufe the slider to move out the other way from the centre in its groove until it comes again horizontal, when it will be at the greatest throw out, as the turners term eccentricity, and the point of the tool will be at the other end of the longest diameter, having described one half the curve; continuing to move forwards till the slider becomes vertical, it will become eccentric again, and the tool will be at the breadth of the ellipse, having finished three quarters of the ellipse; and in turning the next or fourth quarter, the slider throws out till it comes horizontal, and brings the work to the position where we first fert out, viz. at its greatest eccentricity; and with the tool at the end of the longest diameter of the ellipse.

The simple trammel (fig. 29.) is not easily recognized in this complicated chuck, although it has all the same movements. Thus, let us return to our first idea of a board with two crofs grooves in the back of it, turning round on two fixed pins, which enter the sliders in those grooves. Suppose that one of the pins is extended to a large ring, and the groove proportionably widened to receive it, this will have the same effect. Such a groove is formed by the two pieces of steel \( n, n \), which have ftrait edges made truly parallel to each other, and perpendicular to the length of the slider which carries them. The other fixed pin is represented by the mandrel; and the slider being always confined in a right line across it, has the same effect as a pin entering a ftrait groove.

This ingenious apparatus was invented early in the last century by the celebrated mathematician Abraham Sharp. Before his time, oval-work was always turned in a rofe-engine, which had an elliptical pattern.

In turning oval work, the tools must be delicately used, because the circumference moves with an unequal velocity at different parts of its revolution.

Method of ornamenting turned Articles by an Eccentric Chuck.

This produces a similar effect to the rofe-engine; but as a chuck of this description can be applied to any lathe which has a mandrel and slider, it has been referred for the present article.

Figs. 18. and 19. are two views of an eccentric chuck: a
is a socket, which is screwed to the mandrel; and bb the chuck, which is formed in the fame piece with the socket a; a dove-tailed groove is formed in the front of the chuck, by means of two pieces d, d, which are screwed to the chuck, and into this groove a slider, e, e, is fitted; to this slider a centre pin is fixed very firmly, and upon the centre pin a figure, f, is fitted, so as to turn round freely; in the front of the circle a screw, g, projects, for the purpose of fixing chucks to the circle. The slider is applied to the chuck, just the fame as in the oval chuck, but is not left at liberty to slide in the groove, for a screw, k, is applied, which will move the slider gradually in the groove, but always holds it fast where it is placed. By means of this screw, the centre pin of the circle, f, can be made either to coincide with the line of the mandrel, or it can be set with any required degree of eccentricity from the mandrel, as is shewn in fig. 15, by the difference between the line of the screw g, and that of the socket a. The circle is divided round the edge with notches or teeth, cut at equal distances; and a tooth or catch, h, is fitted on the slider by a centre screw, and has a tooth which can be inflected into any of the teeth at pleasure, and will hold the circle fast from turning round upon its own centre pin. In this case, any piece of work, which is fixed to the screw g, will turn round with the mandrel, just as though it was fixed immediately thereto. The manner of using this tool is as follows: when the excentric chuck is screwed to the mandrel at a, the screw, k, is turned, until the screw, g, is brought exactly into the line of the mandrel. A wood chuck is now screwed on at g, and a piece of work fitted into it; which work is turned to its required figure, just as though the wood chuck was screwed to the mandrel itself, without the interposition of the excentric chuck, which hitherto has been passive. The work being turned, it can be beautifully ornamented on the flat surface, by tracing a number of circles upon it. To do this, turn the screw k, until the centre of the circle, f, is removed to a given distance from the line of the mandrel; now apply a tool to the end or flat surface of the work, by means of the slide-reel, and turn the mandrel round, until the tool has cut a fine circular line in the surface of the work. Now it is evident that this circle will not be in the centre of the work, but removed from the centre thereof a distance equal to the degree of excentricity given to the slider. Having thus described one circle, flop the lathe, and release the catch h; then turn the circle, f, round one tooth or notch.

Put the lathe again in motion, and describe another circle by the point of the tool, held exactly in the fame spot as before; but the circle so described will fall on a different part of the work to that circle which was before made, although its centre will be at the same distance from the centre of the piece of work. The lathe is flopped, and the circle, f, turned round another tooth: a third circle is then described; and when as many circles are described as the whole number of teeth in the circle f, the ornamenting is finished. It will consist of as many circles as there are divisions in the circle f, all of an equal size, and their centres arranged at equal distances, around the circumference of a small circle, which is concentric with the work. The whole produces a rosette or engraved figure upon the surface of the work, and the numerous interjections of the excentric circles have a very pleasing effect to the eye. This kind of work is seen on the cafes of many watches; and when well executed, is much esteemed.

**Turning Horizontal Hand-Mill, in Rural Economy, an useful contrivance of the hand corn-mill kind. It was invented by Mr. Wright, and consists of a fort of tub or box; the frame of the mill-part of which is three feet square, and three and a half in height. The mill-stones are eighteen inches in diameter, and inclosed in the tub or box, supported by two crofs-beavers, under which is a lever, having an iron pin or pivot, which runs through the centre of the bed stile into a socket in the bridge of the upper stile or runner, to which is attached the shaft and spindle, running through the eye of the runner and hopper, and supporting the fly-wheel and crank. A piece of wood of a round form, fastened on the shaft, serves as a feeder; and above is a screw to regulate the feed according as the mill is turned. On the side of the tub or box is a thumb-screw, fixed to the lever underneath, which regulates the stones, according as they are turned. The shaft runs through the crown-tree or crofs-bar at the top of the frame, on which is the horizontal fly-wheel and crank; to which are attached one or two handles, by means of which the mill is put in motion. Under the stones is a drawer; in which are placed three sieves of different fizes; one for taking away the broad bran, another for the coarse pollard, and the third for fopping the fine pollard, and letting the flour pass into the drawer, which is effected by a fort of iron fork running through a hole in front of the drawer, and fixing on one of the fieves.

Small hand-mills of this nature are extremely convenient and uful in many cafes.

**Turning Palisades.** See PALISADE.

**Turning-Evil, in Cattle,** a difeafe that caufes them frequently to turn round in the fame place. It is also called the **furdy**; which fee. See TUR in the Head.

The common remedy, recommended by Mr. Markham, is to throw the beast down, and bind him; then to open his skull, and take out a little bladder, filled with water and blood, which usually lies near the membrane of the brain, and then gradually heal the wound. Boyle's Works, abr. vol. i. p. 87.

**Turning to Rot, in Agriculture,** a term used in tillage to signify ftriipping, ribbling, baulking, and combing, according to the manner in which it is performed. It is the leaving of a narrow strip of ground whole, on which the furrow-flunce is turned. It is much used in Devonshire, Cornwall, and fome other diocifts.

**Turning to Windward, in Sea Language,** denotes that operation in failing, in which a ship endeavours to make a progreas againft the direction of the wind, by a compound course, inclined to the place of her destination. This method of navigation is otherwife called plying. See TACKING.

**TURNIP, or TURNIP, in Agriculture,** a moft uful and nutritious bulb-rooted plant, of which there are many different sorts in cultivation by the farmer. It has been long known in this country, but only more lately introduced as a field-crop, probably from Holland, or the Low Countries. It is from a more general introduction of this root into field-husbandry, that much improvement and advantage have been produced, not only in the management of arable land, but in the general system of feeding and supporting different kinds of live-stock. The culture of this root has, indeed, contributed much towards exploding the expensive and wantful practice of naked following, as well as to cleanse and ameliorate the foil, and render it more abundantly productive.

The turnip belongs to the genus brassica, and is well-known by its having a round, or rather long, fleshy, catable root, that varies considerably in these respects, as well as size and colour, in different sorts, under the state of cultivation. The leaves proceeding from the top of the root in 3 M
the middle part are large, and mostly of a full green colour, being ragged on the edges. The item arises from the midst of these in the second season of the growth of the plant, to the height of four feet, or more, producing a yellow flower, with cylindrical pods of some length, filled with small purple, or reddish-brown coloured seeds. See Brassica.

All the different sorts of this excellent plant are, for the most part, distinguished by the form or shape of the bulb or root, which appears in some measure to depend upon the diversity of soil, and the nature of the culture of the plant. But the sorts that have been had recourse to as field-crops, with the greatest success and benefit in different parts of the country, are principally of these two kinds; those having a round or flattish-formed root, that rests much on the surface of the land, and those in which the root is of the more long tap-rooted form, penetrating deeper into the mould with the lower part of the root, but flanking higher above it with the upper portion of the bulb.

In the first, or round flat-rooted sort, there is likewise much variety in the appearances of the tops as well as the roots, though the latter are mostly a little round and flattish. They are commonly distinguished in field-culture into the red-round or purple-topped, the green-topped, the white-topped, the yellow-topped, the black or red-topped, the hard or stone, and the Dutch turnip.

In the latter, too, or long tap-rooted sort, there is some degree of variety in their roots. They are usually known and discriminated by the farm-cultivator under the titles of the tankard, the tap-rooted, the pudding, the oblong, the long, round, and the hardy or French turnip.

It may be noticed, that the different varieties of the former of these kinds of turnips, in consequence of the roots of them being formed more on the ground close to the surface, than in those of the latter kind, which often stand high, naked, and much exposed in their upper parts, above it, are better suited to the purposes of general field-culture, in cases where there is much risk of their being hurt by the effects of frosts in the more severe winter months; but that in other cases, as where they are to afford an early feed, as for suckling cows, and in the fattening of forward sheep at an early period, the latter kind may be had recourse to as the most proper and beneficial. This is said to be the practice of some districts in the vicinity of the metropolis, where it is of importance to have forward lambs.

In different districts where this root is largely cultivated, different sorts of this plant are employed; and it is not improbable that some sorts may be more proper for some qualities of land than others, though little has yet been done in the view of deciding this point. Nor is it unreasonable to suppose, that among the many varieties of this highly valuable plant, there may not be some which, in addition to their superior hardiness, posses a greater proportion of the nutritious principle than others. It has, indeed, been stated that, in a great northern turnip district, the green-topped and white-topped are generally esteemed as more sweet and nourishing than the red-topped sort, which posses a degree of bitterness, and is diploped soon to become stringy and bad as food: that the white-topped sort, on the better kinds of land, is probably the most proper and beneficial, as while it has the property of being hardy, it grows to a large size; and that this and one of the stone or small hard sort, are the most commonly grown, and held in the greatest estimation in some of the best turnip districts still more towards the north. The latter of these sorts is, indeed, by some farmers in those districts, supposed to offend the fertility of the winter season much better than most of the other sorts; but then the produce on the acre is commonly much less. And by others in more southern districts, it is thought to bulb quicker, to have a greater solidity, a finer grain, a thinner skin, and to be smoother in the crown of the bulb; consequently to be less liable to injury from wetness and severe frost. And that although it may not grow so quick, or to so large a size, the latter of these defects may be obviated by leaving the plants a little thicker on the ground at the time of thinning and setting them out. Indeed, both the white and green-topped sorts are also much grown and approved in all these districts, and by some highly extolled on account of the qualities just noticed, as well as their being of a large growth, and continuing longer in a flate fit for use, especially the latter. The yellow-rooted or straw-coloured turnip, too, is found to be a firm-flaved and sweet-talled nourishing sort, but it has not yet been much cultivated, so that its properties are but imperfectly known. The red sort, which was formerly much esteemed, has now mostly given way to other sorts. And the black-rooted sort is very rarely cultivated in any district of the kingdom; nor even those of the Dutch sort, though the early kind of them might answer well for forward crops. Much might probably be done in getting good sorts, by collecting food from such as are the most hardy, and which grow to a large size, and fowing it in continuance.

In some northern and other districts turnips are grown much in mixture, which is a bad plan, as they have different growths, and of course rise unequally. And in the southern ones, the white globe prevails much in some instances; and the green round sort is found to stand well, and be larger as well as more certain in the produce.

The turnip is a sort of crop which is grown after many other different kinds, as those of a wheat flubbl, a pulse lay, a turn, potatoe, or any other similar kind of crop, as well as after the process of paring and burning the layers of old grass-lands. It is the practice too, in some districts of this sort, to have two turnip crops in succession, as the means of cleaning the land more effectually, which has been found to answer greatly in the barley or other crops that may be grown after them.

The foils which are the most proper for the growth of this sort of crop, are all those of the more light, friable, loamy, medium sandy, and other kinds, which have a sufficient depth; but it may often be raised with successe and advantage on many other sorts, which have the surface mouldy parts sufficiently fine, without there being too much moisture below, as those of the thin gravelly, loofe chalky, and many other sorts and qualities; even on the loamy clays, in some cases, when properly managed in their tillage preparations, and other ways.

A late practical writer has well remarked, that from the successes of the culture of this useful crop, on lands that differ greatly in their nature and qualities, it is plain that the plant admits of more latitude in respect to soil than many other sorts; though an opinion appears to have been too general among the cultivators of it, that it is only capable of being had recourse to with advantage, on such as are of a light, mellow, and open texture and quality. It is suggested too, that this has probably had considerable influence in preventing the culture of the turnip from becoming so general as, from its great utility and importance, it ought at present to have been. But though the turnip may be grown with successe and benefit on soils that vary considerably in their natural friabilities and compositions, it is constantly necessary, for the perfect growth of such crops, that at least the more superficial parts of the soil, or the beds of earth in which they grow, should be in as fine a reduced powdery condition as possible, as more is found to depend
depend on this, than even on the nature or qualities of the soil.

In the view of bringing land into a state of suitable preparation for this fort of crop, much breaking down and reduction of its parts are, of course, requisite. This fort of breaking and pulverization is sufficiently and beneficially performed in many different ways, as by rendering the land more penetrable to the roots of the plants, by promoting the growth of the small weeds more fully on the surface, and thereby making them capable of being more perfectly eradicated, and the young turnip plants, of course, be less endangered by them; while, at the same time, a more fine and mellow bed of mouldy earth is provided for the reception of the turnip-seed, and its vegetation and growth rendered more quick and strong in consequence of the more equal diffusion of moisture that must take place among the parts of the soil. Without such a state of mould in the soil being produced, it is found to be in vain to expect good crops of this fort. In order to provide this state of preparation in the soil, it is the practice in some of those districts where turnip husbandry is carried on in the most complete and successful manner, when the seed is to be put in on a fallow, to have recourse to three, four, and frequently five ploughings or tarrings of the land, having the cloddy parts of it well broken down, between the times, by harrowing in different directions, and the occasional use of the roller or other such means, as by these modes almost every particle of the soil becomes divided, and excep tedly to the influence and action of the atmosphere, and perfectly aerated and saturated with moisture. In these cases, some advise that the first operation should be performed towards the close of the year in a shallow manner, so as merely to take off the rough surface; the land may then remain in this state until just before the beginning of the spring, when it should be well broken and reduced by harrowing, and then crossed-ploughed to the full depth. When the land is weedy, it should be again broken down by the harrow in the course of a little time; but when clean, it is better to remain in its rough state. In this condition it may then be left until the spring be a little advanced, when it should have another ploughing to the full depth, and where the seafon is dry, and the soil of the more heavy or stiff kind, be immediately after harrowed, but where it is light, this may be deferred for a week or two. By repeating these operations sufficiently, the soil is most soon brought into a fine clean state of preparation for the crop.

Others, however, think the first ploughing should be deep, and the after ones and harrowings be continued to a later period, but at the same time, suggest, that they must, in general, be much regulated by the nature of the soil, the circumstances of the seafon, and the convenience of the cultivator.

In preparing fallows, as well as other lands for turnip crops, some, in different places, besides these means, make great use of scarifiers and feafifiers, and find them particularly beneficial in foul states of them.

Where the seed of this fort of crop is, however, to be put in after corn, early peas, tares, or other such crops, the preparation of the land is seldom carried to such an extent of ploughings and other operations. Much fewer are commonly thought sufficient for the purpose, as two, or three at most.

In preparing for this crop, after the surfaces of coarse pasture or other grassy lands that have been long in that state, old flintstone beds, or downs, have been taken off and reduced by means of paring and burning them, the practice is to have recourse to once ploughing over the lands in a light manner, the ashes having been previously spread out equally on the surface. In this way the most advantage is afforded to the turnip crops, and they have been well produced by it.

There are some other local practices of preparing for turnip crops, but they need not be noticed in this place, as being only of little use in certain cases.

In the application of manure in the preparing of land for this crop, in the first of these ways, and where it is of the calcareous kind, such as lime, marle, or other similar forts, it may be the best mode to make use of it after the second or third ploughing, especially in the former of these kinds, in the proportion of from one and a half to about three chaldrons, or thirty-two bushels; and in that of the latter, from eight to ten or fifteen ordinary cart-loads to the acre, as the circumstances and nature of the land may be; as in this manner such matters may become the most perfectly blended and incorporated with the mould of the soil. Each of these forts of substances has been found highly useful, in this way, in several different districts of the kingdom.

It is, however, clear, from the success of different cultures of this fort of crop, that the substances of the dung-kind, where they can be fully supplied, and used in the preparation of the land, or other ways, are the most fitted to the growth of the root. And that for such soils as possess a proper degree of lightness, and are in a fine mellow state of mould, those which are in the more reduced, or rotten short condition, may be the most suitable, as they are capable of being the most intimately mixed and incorporated with them; but that where they are more close and heavy, the longer and less reduced kinds may be more proper and beneficial, as they will not only tend to preserve these soils in a more open and loose state, but by their more gradual decay in them, render the earth more friable and mellow. Some, however, think them best applied in the medium state between these extremes. This fort of manure, when used in preparing land in this intention, should vary, in some measure, not only as the nature of the soil may be, but according to the manner in which the crop may be cultivated; in general, however, it should be put into the soil as nearly as possible to the period at which the seed is sown; as, in this case, in consequence of the new fermentation that necessarily takes place in the soil, the crop receives the most benefit from it. When, therefore, the crop is to be put in, in the broad-call manner, the dung may be spread out equally over the land, and be turned in with the seed-furrow; though some advise it to be lightly turned in by the ploughing that precedes the seed-earth, and to be well intermixed with the mould of the soil, by harrowing immediately before that earth be given. The former would appear, however, to be the better practice, especially when the manure is in a sufficiently reduced state, as the plants will have the most full advantage of it. The quantity must necessarily depend in a great measure upon the different circumstances of the soil, and the richness of the duny material; but less than from ten to twelve good three-horse cart-loads can seldom be made use of with advantage on the acre.

Where earthly and other matters, in mixture with dung, are had recourse to in this way, after being well prepared, as is sometimes the case, the proportion should mostly be considerably larger.

In cases where the crops are put in, in the ridge or drill manner, as the manure is wholly confined to the middle parts of the ridged-up earth, and does not occupy all the superficial portions of the land, a somewhat less quantity of it may answering the purpose; though a full and rather liberal allowance
allowance should always be made, as the safety and success of the crops depend much upon the rapidity and strength with which the young plants are at first pushed forward by such means.

In whatever way this fort of manure is made use of in this preparation, it should constantly be applied in an even manner, and be turned into the soil as soon as possible afterwards; as where this is not the case, great loss must often be sustained by the diffipation of the more liquid parts of it.

There are many different practices, in the preparation and application of this kind of manure, recurred to in different districts, in using it for the purpose of raising turnip crops, as may be seen by consulting the Corrected Agricultural Report of the County of Norfolk; and different kinds of it are sometimes preferred by cultivators, as that from fattening beasts, hogs, and the sheep-fold. But good clean dung of any sort is capable of answering the purpose.

The dung of rabbits, poultry, and pigeons are occasionally used with success in the raising of crops of this sort, after being rendered dry, and dispersed over the surface of the land in an equal manner. They are mostly used for this purpose in the quantities of from about twenty to thirty bushels to the acre, just before the time of sowing the feed. And as they require to be put into the soil to only a slight depth, harrowing may, in many cases, be sufficient for the purpose, or a very light and shallow ploughing. Rape-cake has long been employed as a manure in some districts, in preparing for turnips, as that of Norfolk, by having it fown over the land in a carefully reduced state, five or six weeks before the time at which the feed is to be put into the soil, in the quantity of about a ton to three or four acres, and leaving it in, or turning it in very lightly at the period of sowing. But it is considered a great improvement by some, and practised to much extent by Mr. Coke, of the above district, to have it ground by proper mills into a perfect state of powder; and applied at the same time with the feed over it, in the drills or small openings in the land made for the purpose. It is effected by a contrivance of the drill kind, that contains alternate divisions, with small and large cups for delivering the feed as well as the cake into the same drills. The stream of powdered cake is thus rendered constant and regular, the proper cups and funnels being capable of ready application. In this way, it is not necessary to have the cake applied before hand, and a ton is sufficient for six acres, by which there is a considerable saving in labour as well as the material. It is said to answer perfectly in the practice, though some dislike it.

Different other sorts of manures that can be reduced into a powdery state may likewise be employed in this manner, in the growth of this crop, with great economy and advantage in many cases. Malt-dust or combs too, might be made use of in the same way with advantage, though it is commonly applied over the surface in the proportion of about twenty facks, of three bushels each, to the acre.

Sheep-folding, in some districts, is used as a means of providing manure for the growth of turnips, from the effect of first ploughing over the land, to that at which the feed-earth is given. From the treading and consolidating of the soil in such cases, it may however be held only to fold during dry weather, and always to plough over the land in a light manner as soon after the sheep are removed as possible.

The quantity of feed, which is necessary must be different in different cases, as a great deal must constantly depend on the nature and quality of the soil, the period of sowing, and the manner and circumstances under which it is put into the ground. In some good fertilized districts in the southern parts of the country, where the turnip culture in the broad-cast method is carried on to a considerable extent, the quantity made use of is commonly from about one pound to one pound and a half; but on those of a more light, and those of the sandy kind, a pound is mostly found quite sufficient; while on some more heavy turnip soils, nearly two pounds are employed. On the calcareous and loofe chalky soils too, a large quantity of feed is mostly necessary. It is indeed, in common, a good practice in sowing for turnips, not to be too sparing of feed, as the unnecessary plants are readily capable of being removed by the first hoeings and thinnings of the crops.

In the culture of the crops in the ridge or drill method, as is commonly practiced in some northern districts, in consequence of the feed being deep in, it is intended to be sown in a regular and exact manner, and the whole of the land not being occupied by plants, a somewhat less quantity of feed may be sufficient.

As the success in the growth of turnip crops has been found to depend greatly on the quick early sprouting of the feed, and the young plants being expeditiously pushed into broad leaf, it may be useful to have the feed steeped a little in water, or some other liquid, before it is put into the ground, especially in dry seasons; but it must become externally dry before it be fown in all cases.

Soaking the feed in strong lecited oils, and drying it by means of brimstone, have likewise been practiced in the view of preventing the destruction of the crops, but probably with but little success.

The time which is most proper for sowing crops of this sort, must be principally regulated by the intentions of the farmer in respect to the dilpofal and use of them; but for the general more early consumption of them, the most proper season for putting them in may be about the beginning of the month of June; but it is intended that the crops should serve as food for flock in the more early spring months, or at late periods, the sowing should take place proportionately sooner or later. Indeed, where the root is grown on a large scale, it may often be of great utility and advantage, as well as very convenient, to have the times of sowing still more considerably varied; as the crops by such means not only come more suitably in succession to the hoe, but are likewise ready for the purpose of consumption by different sorts of live-flock, at the different periods when they may be most wanted.

In cases where the practice of lamb-fuckling is had recourse to for getting them ready foon, it is essential to have crops of turnips as early as possible, in which intention the seed is to be put into the soil often a month sooner than the above period; such land being let aside for the purpose as is well enriched with manure, in a fine state of tillth, and perfectly free from weeds.

In common, however, early sown crops of turnips are not only left sweet and nutritious for flock, but more exposed to injury from mildew and other cases of the same kind, than those which are sown later in the season; but though this may be the case the sowings in no circumstances should be deferred so long as that the plants cannot have time to fix themselves fully in the soil, and cover it well before their growth is checked and restrained by the coldness of the approaching autumn and winter seasons, as in such cases the crops never answer well for the farmer.

In regard to the methods of sowing or putting this sort of crop into the ground, they vary in different districts, but are chiefly of two different kinds, the broad-cast, and the ridge
ridge or drill. In the great turnip district of Norfolk, and most of the southern parts of the country, it is the most prevailing practice to sow this sort of crop in the broad-cast manner on the level surface: while in the large turnip districts of Northumberland and Berwickshire, where this kind of husbandry has undergone complete change, and in most of the more northern parts of the island, it is more common to have recourse to the drill mode, depositing the seed in rows, either in hollows or ridges mostly raised by one bout of the plough, or in drills on the level surface; at the distances of from twenty-four to thirty inches in the former cafe, as the circumstances of the land and the intentions of the cultivator may be, and from ten to twelve or thirteen inches in the latter.

These different general methods may each of them probably be had recourse to with propriety, success, and benefit under different circumstances and qualities of the soil. As on the light, mellow earthy, deep sandy, gravelly, and other similar sorts of land, which are apt to part with their moisture too quickly, and consequently liable to become too dry and parched for the healthy perfect growth of the turnip, it may be the best and most successful practice to sow in the broad-cast or drill mode on the plain or level surface, as by such means, the moisture which is necessary for the crop, may be more effectually retained in the land for the supply of the plants. And on the contrary, where the lands are of a somewhat more heavy quality, and not so much disposed to part with their moisture, but to retain it in a sort of stagnant state, the ridged-up drill method may be the most suitable and advantageous, as by the mellowness and fineness of mould which it affords, and its tendency to keep it dry and preserve the plants from being hurt by the retention of too much wetness about their roots, the growth and security of the crops will be much promoted. It has a superiority too in some cafes in other ways; as on soils which are rather thin in the staple, this plant, in consequence of its long tap-root standing in need of a good depth of mould, can seldom be grown in a perfect or beneficial manner; by ridging up the land considerable advantage may be gained in providing a more suitable depth of cultivated soil for the plants to grow in, and a better bed for putting in the seed, as the operation has been found to more than double the common depth of mould in some such cafes. The plants in this way grow more strongly, and besides, by the manure being confined to the ridges on which they grow, are less exposed to the atmosphere, and not demanded in so large a quantity, in consequence of which more land may be employed in raising this sort of crop; while by its concentration, and the seed being placed more immediately upon it, the nourishment and means of support to the plants may be more fully and effectually supplied, and a larger produce, of course, be afforded. This mode of sowing may be beneficial too in affording the means of more easily and readily getting up the crops, as food for flock in particularly severe feasons, when cattle off very early in the winter months. It is of importance also in several other circumstances, as the hoeing, working, and cleaning of the land between the rows of the plants can be easier, better, and more perfectly executed, less expert persons can be employed in much of the work, and from the earth or mould being laid up to the plants by the use of the plough or some tool of that kind, the roots of the crops are better protected and preserved from the effects of severe frosts and other causes of injury. They can be raised in this way like-wise on land that has been less prepared and is less dry, as the tops of the ridges are preferred by it in a proper state, and the crops are mostly more abundant in this manner of sowing.

Different objections have, however, been made by some to the ridged or raised drill method of putting in the seed; but the principal of those that appear to have any fort of weight or importance are, that in consequence of the roots of the crops, in such cafes, being more elevated or standing higher, they are, on account of being so much exposed, less capable of standing the severity of the winter season; and that larger spaces or distances are allowed than are necessary for the roots to attain a proper size in, consequently that the quality of produce on the acre will not be so great. Notwithstanding the latter supposition, it is probable, however, that from the nourishment or food of the plants being so greatly increased, and the growth of the crops thereby rendered so much more healthy and strong, the amount of the produce must be increased rather than diminished. Different statements and calculations would indeed seem to shew this to the cafe, and that even a greater weight of turnip is raised on wide intervalled ridges than those that are narrow within certain limits.

It has been contended too, in opposition to the raised mode of sowing, that there is difficulty in restoring the land to the level it was again, and that the ground in the intervals becomes injurious in consequence of the want of moisture; but by forming the ridges in a suitable and proper manner, according as the nature of the soil may be, all these inconveniences may readily be removed. In this intention, it has been advised to form the ridges in diagonal and other directions over the fields, keeping the lands dry. It is further objected to the raised practice of sowing, that in lands of the more heavy turnip kinds, which have little irregularity of surface for taking away moisture when in excess, though larger crops of this root may often be produced, the grounds are so much injured by being poached in getting them off, that the crops of grain or other kinds which succeed them, are lessened in a far larger proportion than it is compensated by the greater value of the turnips. In such cafes and circumstances, it is advised, as more beneficial, to form the land into large ridges, so convex as to throw the wetness quickly into the furrows, as about fifteen feet in width, that a cart may be easily passed along them without prefilling the earth in and obstructing the furrows on the sides, the seed, where the land is different to throw up weeds of the annual kind, being sown in the drill manner on the surfaces without being raised, as by that means the work of hoeing may be rendered more easy and convenient; but where this is not the case, and where the seed is put in at a late period, or the land much infested with the grub, it may be preferable to have recourse to the broad-cast mode of sowing, as being more certain, from the plants being left so much closer to each other at the first hoeings, as to admit of thinning out and removing the bad and unhealthy ones in the succeeding operations of the same sort. Besides, they are supposed to have the advantage of growing more strongly, from the shelter being more complete, and from the ground being left's flourished about them in their early growth, before their tap-roots are sufficiently fixed in the foil to support them perfectly.

It would, however, appear from the success which has attended the sowing and raising this fort of crop in the ridged-up or other drill made in different districts, and from the greater facility and cheapness of performing the necessary after-culture, that it is, in many instances, the most beneficial manner of sowing; but that the nature of the ridges or drills, and the distance of the rows, must often require to be varied according to the quality of the soil, and many other circumstances. See a paper in the second volume of "Communications to the Board of Agriculture," for the
comparative benefits of the drill and broad-calt methods of fowing, as ascertained by experiment.

In explaining the practices which are mostly made use of in putting in turnip crops in the above two different methods, it may be observed, that where the former or broad-calt manner of fowing is in use, which may be proper and advantageous in some cases, as has been just shewn, it is of much consequence to their success, that the more superficial parts of the land be brought into as mouldy and fine even condition as possible previously to the putting in of the feed, and that in fowing, the feed be dispersed over the surface of it in as perfectly even and exact a manner as may be, as soon as it can be done after the ground has been made ready, as upon these circumstances being well attended to, the goodness and abundance of the crops in a great measure depend. An expert feed-man is required for performing this sort of work, but as it can seldom be done by the hand in a suitable manner by persons who have not been long in the habit of putting in small feeds in this way, a fort of box or trough has been invented and constructed for the purpose, which is in frequent use; and when proper care is taken to prevent the perforations of it from becoming obstructed by two or more feeds being fastened in them, it is of great utility in dispersing the feed in an uniform and regular manner over the surface of the land. After this has been properly effected, the feed is mostly covered in, in a shallow manner, by means of harrowing, a light short-tined harrow being used for the purpose, as from the turnip plant forming its bulb in some measure above the surface of the ground, it should not probably be put in to too great a depth in the soil. Some advise the palling of the tool twice over the land only in the same direction, in the first going slowly, and in the latter more quickly, in order to give a nearer finish and finer surface; the ridges having been laid out to the breadth of from four to ten yards, as the land may be inclined to be more or less hilly. This is the Norfolk practice of some measure, and found to be extremely beneficial in many cases of broad-calt fowing for this crop.

In the drill method of fowing turnips, the land, after being prepared in the manner already described, is either formed into little ridges by the plough, and the feed put in, in drills upon them, or these are strick in the level surface, as noticed above; but the first is by far the most common. In the great turnip-drilled district of Berwickshire, the little ridges or drills, in cases where the ground is not well reduced, but remains in rather a rough and cloddy state, are, it is said, formed with the common fowing plough, drawn by two horses, which lays together three or four small rinds or furrow-slices for one fuch ridge or drill. But that the most common and expeditious method of laying up these ridges or drills is by a double mould-boarded plough, which has the boards hung on the sheath with hinges, and which can be fet wider or narrower, as may be necessary. This too is drawn by two horses abreast, and forms two sides of the little ridges or drills at the fame time; the width of the ridges or drills being commonly, as has been seen, from twenty-seven to thirty inches. In cases where the large ridges or lands are not much rounded, the little ridges or drills for fowing on are not laid in exactly the course of them, which is mostly parallel to one or other of the sides of the fields, but are angled a little, for the purpose of having the manure better mixed with the soil, when it comes to be ploughed up into ordinary ridged lands or banks for other crops, after the turnips have been eaten or taken off the ground, as already suggested.

But in another district, where this mode of fowing turnips is largely practised, in the extensive cultivation of the root by some, the manner of performing the work is, after the land has been prepared and made very fine, as directed above, for the ploughman to set up three flarks or poles in a right line where it is thought most proper to begin, and by having the horses yoked double, and driven by himself with cords, these poles are seen between the horses, and by keeping the plough to bear always upon the poles, the first furrow is drawn as straight as possible. In returning, the far-side horse is kept in the new-made furrow, and the plough at such a distance as to form a one-bout ridge or drill in a complete manner, which has somewhat this appearance $\Delta$: by proceeding in this manner over the whole, the land, when finished, displays the forms of alternate little ridges and furrows in this way $\Delta\Delta\Delta$; the distances of which are mostly as stated above, as smaller ones do not admit of ploughing between the little ridges or drills. However, in the practice of the former of these districts, the land when ridged up or formed into narrow raised divisions, the ridges have a left sharp form: thus $\Delta\Delta\Delta$

In the latter of these districts, or that of Northumberland, the next proceeds are those of applying and turning in the dung or other manure into the little ridges or drills, which is effected in this way: a cart goes down every third interval between the small ridges or drills, and lays such matters in small heaps in it; when labourers, as women and children, are ready, and with small three-pronged forks place them out evenly in the bottoms of the three furrows of the ridges or drills; that is, in the one where the matters are dropped, and in those on each side of it. This being done, the ploughman splits the one-bout ridges, and covers up the manure exactly in the middles of new-formed ridges of the farm fort: but before the fowing can take place, the tops of the ridges require to be flattened, which is done by means of a small roller, four feet eight inches in length, and nine inches in diameter, which flattens two ridges at once. On the tops, and exactly in the middles of these flattened ridges, the feed is deposited in small openings, made by one or more drill-fowing implements tied to the roller by a rope of fix or even feet in length, at which distance the roller is followed, the fowing-drill or tools being guided by a man, the work when finished appearing in this form $\frac{d}{a} \sqrt[\alpha]{d} \sqrt[\alpha]{a}$; the letter $r$ shewing the place of the feed, and $d$ that of the substance used as manure. The ridging-up the land, and covering in the manure, are done in the same way as in the first district, by ploughs of the fame kind.

And in the mode of this district, or Berwickshire, the work of manuring and covering it in go hand in hand, and succeed each other as fast as possible; the matters thus used being laid in heaps in the furrows of the different ridges or drills, from the third to the fifth; the distance of from eight to ten feet, and immediately put carefully in along the furrows of them, when a few being completed from end to end, the double mould-boarded plough is used, as before, to split the ridges or raised drills, and cover in the manure, which it does at one bout, leaving the ridge-tops immediately above the manure put in, rather high. These are sometimes here, in some cases and circumstances, a little levelled down before fowing, in a fort of sharp convex manner, by a light harrow run once or twice over them. But the most usual mode of flattening them is by the light wooden roller, as above, to which the drill or fowing-plough is attached, in the manner already seen. Sometimes, however, instead of the roller, a kind of sled, made of wood or iron, is had recourse to in some places, for flattening the tops of one or more
more about ridges; but the light rolling mode is much the neatest, most convenient, and ready manner of executing
the work.

There are different other modes and practices of perform-
ing the business of putting in the feed, in the ridged-up and
drill manners made use of in different places; but as they
are not common, or of much practical importance, they
need not be mentioned here.

In putting in the feed of turnip crops in this way, a great
number of different kinds of drill-owing implements and
contrivances are made use of; but those wrought by horses,
and which are so formed and attached in their different parts,
as to perform all or most of the several operations of the
process at the same time, are, in general, the most proper
and convenient for the purpose. Whatever contrivance of
this nature is, however, employed, it is constantly necessary
to take care that the feed be regularly delivered and put into
the furrow; as from the smallness of the perforations in the re-
volving cylinders of most of them, the feed is liable to be
obstructed in falling, and the regularity of the delivery and
owing thereby prevented.

Every district has mostly its favourite drill-owing imple-
ment for this purpose. In the first of the above, they, for the
most part, make use of a tool of this sort forowing turnips,
which has a cylinder or small barrel of white iron or copper,
and that is mounted on an axle with two wheels. The bar-
rel is perforated with holes at equal distances, and as it turns
round with the wheels, the feed falls equally out, and ex-
actly in a straight line. This cylinder and wheels are fixed
to a light frame-work, which has two rollers, and is kept on
the top of the ridge or drill by them, by a man or boy, who
walks behind, as in managing a common plough. Before
the cylinder there is fastened to the frame-work a fort of
counter, which makes a kind of small rut-like opening for the
feed, and behind is fixed a rake with two or three teeth,
which mixes the feed that is dropped with the mould of the
furrow, and covers it; and as the horse and implement return
by the next furrow or interval to the right or left, the oppo-
site end of the roller rolls the ridge down, and compresses or
flattens the top of that on which the owing implement fol-
lows. When it is necessary to do much work at a time, two
owing tools are had recourse to, which follow the same
roller, and two ridges at once, and the feed is rolled in by a
second roller.

An improved tool of this kind has been invented, which
flattens two ridges or drills, forms the little ruts or openings
on their tops, puts in the feed, and covers it in all at the
same time, by which much faving in tools and labour is made.
It is a very complete implement forowing in the raised
ridge or ridge method. It is made and much used in Ber-
wickshire.

Sometimes the roller used for the feed in these cafes is a
kind of low broad wheel, which is attached to the owing
tool, and rolls only on the track or rut where the feed is put
in, which may answer where the work is on a small scale.

On fine land, fully prepared with reduced dummy matter,
and on which it is considered unnecessary to horse-hoe, a
owing implement of this sort is sometimes used, which is
attached to the common fowing-plough; and one tool follow-
ing the other, the feed is sown in rows, at a regulated dis-
ance and depth. This tool and mode of owing answer
well in such cafes, and are much employed in some parts of
Yorkshire.

In cafes where powdery substances of the rape-cake, or
other such kinds, are to be put in as manure with the turnip-
feed, in this way, a owing implement of this sort has lately
been contrived and had recourse to in some of the southern
turnip districts, with much utility and benefit. It sows the
feed and duff in regular lines and quantities, on two ridges at
the same time, the horse passing in the furrow or interval be-
tween them. This is effected by having proper cups and
funnels for depositing the cake in addition to the other parts,
as seen above. It is a very complete and useful tool for the
purpose.

Where, however, the feed is to be sown in the drill man-
nery on the level surface, without its being raised in ridges, as
is the practice in some districts, especially when formed at
narrow distances, as not more than twelve or thirteen inches
apart, the larger contrivances of this sort, which sows a
number of rows or drills at the same time, may be the most
proper and advantageous, as being more quick in performing
the work. There are many other implements of the same
kind, which are useful, and suited to different cafes of owing
in this way. See Turnip-Drill.

In whatever manner turnip-feed is put into the ground,
experience has shewn that it is of much consequence to have
it done in such a way, and under such circumstances, as
that the germination and early growth of it may be in as
ready a manner as possible, as upon this a great deal in the
goodness of the crops depends, as has been already seen.
It has been supposed by some that the feed, in order to se-
cure these effects in the most certain manner, should be put
into the soil to the depth of three or more inches; and that
the superiority of the drill method of sowing partly arises
from the feed being placed to a greater depth, and growing
more rapidly, on account of having more moisture, so as to
have the plants become sooner out of danger from insects, or
other such causes of destruction; while others think, from
these circumstances, that it should be covered in only in a
light manner.

A late able practical writer, however, suggests, that as
air is necessary as well as moisture to the vegetation of feeds
when placed in the ground, it would seem probable that the
quick sprouting and growth of such crops may be the best
and most effectually secured, by only putting them into a
middling depth, and according as the particular nature of
the land, and state of the soil may be, as from an inch and
a half to about two inches, as the soil or seed may be in-
clined to be wet or the contrary. In this way, it is be-
lieved, the inconveniences arising from the feed being too
much parched and dried by being exposed near the sur-
face, and from the want of the action of the air on account
of its too great depth, may be equally avoided. As crops
of this sort are, for the most part, put into the earth during
the hotter months, there is another circumstance that may be
of equal consequence, it is supposed, in promoting the
quick shooting and growth of the young plants; which is,
that the feed, especially in such hot seasons, will imbue
with moisture by soaking it, and consequently with the oxy-
gene principle of the air, as already suggested, before it is
committed to the ground; as by such means, there will be left
required to be drawn from the mould of the furrow which fur-
rounds the feed, and the processes of vegetation almost imme-
diately takes place. Sir George Staunton, in his account of
the "Embassy to China," as well as Mr. Gillet, in the
"Bath Papers," have likewise ascribed the preservation of
turnip-crops in that country as well as this chiefly to this
practice; and by it good crops of this sort may often be pro-
duced, where they would otherwise almost wholly fail. And
the correctness of the practice and principles on which it de-
pends, is further supported by the success of the general cus-
tom of putting in these crops on the moist, new or fresh turned-
up mould. Some interesting and useful observations and
experiments on the shooting and growth of turnip-feed, may
be
be seen in a pamphlet "On the Failure of Turnip-Crops," by the Rev. H. B. Stacey, but which we have not room to introduce here.

After-culture of the Crop.—It is of much consequence in the production of good crops of this fort, to have this part of the culture of them well performed, and at such times as are most suited for promoting the growth of the young plants, as well as preventing those of the weed kind from rising and injuring them by the shade and obstruction which they produce; as without considerable attention to these respects, the labour and expense employed in preparing the land, and putting in the crops, must, in a great measure, be thrown away. From the want of a sufficiently adequate re-turning, this end is often not accomplished. This is usually accomplished by means of the hoe, in some way or other. Where the crop has been put into the soil in the broad-cast manner, the hand-hoe only can be made use of for the purpose; but where the feed has been sown in rows by the drill, or in other ways, and a sufficient space of interval allowed, those of the hoese kind may be employed, either alone, or in addition, after the plants have been properly set out in the hand manner, to suitable distances.

It is the common practice, when the plants have produced four or five leaves, or when they cover a circle of three or four inches in diameter, which mostly happens, in favourable seasons, in the course of about a month or six weeks from the time of the feed being put in, to begin the different operations in this fort of work. In the first of which, such plants as stand too close are to be struck out, to leave the others at a suitable distance, according as the circumstances of the feason, the nature of the foil, the period of fowing, and the use to which the crop is to be applied, may be. When the feason is hot and dry, the striking out of the plants in the firft hoese should not, however, be fuch as to leave them at too great a distance; as by keeping the remaining plants pretty clofe together, the moisture may be better preserved in the land, and the crop rendered more fecure; but in rich soils, when early fown, and when intended to be continued by flock at an early period, a greater striking out of plants at first may be advantageous.

In the practice of some, the moft ufual custom is to leave the plants in the firft hoese at the distance of from fix to eight inches from each other, but others prefer a fll greater distance. In the second hoese, which should be performed in the course of about a fortnight, or three weeks, from the firft, according as there may be a neceffity, the plants that are to remain for a crop may be left at the distances of from eight or nine to twelve or more inches in the broad-cast practice, and at those of from nine or ten to fifteen, or a greater number, in the rows where the drill method is employed.

In these second hoesings, the mould between the plants should always be well firred, in order that it may be rendered perfectly mellow and well aerated, and any weeds that may have rifen be effectually destroyed. The future hoesings that may be neceffary in crops of this fort are to be regulated by the particular circumstances of the fields; but the mould should never be allowed to become too thick and compact about the roots of the plants, or any weeds be suffered to interfere with them.

It is the practice in some places, especially with the broad-cast crops, to pass a light harrow over the land once in a place, as soon as the plants are sufficiently strong, in order to render the first hoeding more effectual; and even in particular cafes, where they push forward rapidly, it is made use of after a second time in the contrary direction. In performing the work, however, great care is neceffary, particularly when the plants are thin upon the ground, as otherwise too many of them may be dragged up, and the crop be much injured from the want of a fufficient plant.

In the ridged crops in the latter of the above drilled turnip districts, it is the practice, when the plants have got four leaves, to begin to hoe, leaving the plants at only eight or nine inches distance in the rows; and as they have to much room sideaways, or from row to row, the hoers go in that manner and pull out the surplus plants, weeds, and other matters into the furrow or hollow space between ridge and ridge, and the turpis plants are let as regular as if they had been planted out with the greatest care and exactness, the work being performed by women and children at but a trifling expense. After this, when the plants left have perfectly recovered and established themselves again in the foil, as is mostly the cafe in about eight or ten days, the earth is taken from the rows where the turnip plants stand, by a light plough contrived for the purpose, and turned upon the pulled and struck-out plants and weeds left by the hand-hoers, in the furrows or intervals of the ridges, and when they have once more recovered themselves from this part of the work, and are become again in a vigorous state, or when other circumstances render it neceffary; the mould, which was in the former process turned from the turnip rows, is now divided and laid up equally to the different rows by the fame tool, or a similar one with a double mould-board. By these means, where the land is clean and free from weeds, the work is completed; but when the contrary is the cafe, additional hoesings and ploughings are given, according as the state and other circumstances of the land may be.

But in the former of these districts, where the horse as well as the hand methods are had recourse to, they proceed in a different manner. In the former or horse mode, when the turnip plants are from one to three or four inches high, or when weeds begin to appear, a small light common plough of the swinging kind, drawn by one horse, goes along one side of the ridge or drill, and turns off the earth from the young plants, and returns on the other side, doing the fame, leaving the plants standing on sharp ridges. But sometimes, instead of this plough, the work of turning the earth off from the different sides of the plants on the ridges is done by a tool of the fame nature, mounted with two sharp coulters, which cut or pare from both sides at once, and which on smooth fine land performs the work equally well and much more expeditiously. It is indeed an excellent tool for the purpose, when properly formed and made use of in the work.

In the latter or hand method of hoeding, which is had recourse to two or three days after the earth is turned off from the plants, the hoers go to work, making use of a hoe of from five to eight inches in breadth, and at one stroke of the foil, cross the ridge, cut out the weeds and unnecessary turnip plants, and leave the crops sufficiently thinned and let out for air.

When the crop has been hoed and hand hoed in this manner, the field is left in that state for ten or fifteen days, and if weeds grow fast, the fame work is repeated. In ordinary circumstances, the whole work of hoeding and hand hoeding only costs about 7s. the acre.
TURNIP.

It has been suggested by a large cultivator of this fort of crop, that these advantages may be equally well attained, and with more success and less danger and inconvenience, by means of paring only one side of a ridge at a time, leaving the other to be performed some time afterwards. It is thought too, that this practice of paring one side only at a time with a single plough, and leaving the other untouched for several days, has many important ufses and some superiority. The tool, in this manner, is capable of going nearer to the plants; the drought has not so much imprefion on their growth; and the land has more benefit from the atmosphere by being flurred at different times, than when the mould is directly thrown into its first bed, as in the common manner.

In this mode of proceeding, the work is reversed at times in an alternate manner, and continued as long as a paflage is allowed to the plough by the flemes of the turnips; and they are never set up at all.

Much advantage in the hocking of turnip crops may often be gained by having the feed plow in at different times, as by this means fix labourers have been found capable of performing the work twice over more than one hundred acres, while in the contrary circumstances, a much larger number is always necessary for the purpose. See Hocking.

In the hocking culture of turnips, many different tools of different forts are in use; but in the horfe method, the work can be well and correctly performed by any light small plough. In this work, some one which is about five inches in width at the bottom, and eleven at the top, which answers well for working the intervals of the drills or ridges. But in letting or earthing up the rows, one of the double mould-boarded fort is probably better, as being more expeditious and convenient. Improved tools of this fort have been contrived, with coulers that are moveable, for cleaning these crops, which by their capability of being readily set to different distances, fo as to fit the different widths of the rows, not only perform the work of paring off and removing the earth from the different fides of rows at one operation, but which, by having their earth-boards fo attached, as to be set differently as to width, effect the work of moulding up the plants. In managing the bufh-nea by this tool, there is evidently not only an advantage in double the quantity of work being performed, but in the different operations and proceedes of it being effected in a more correct manner, such as that of flurring the mould in the intervals of the ridges or drills, and the application of it to the flemes of the young plants on or in them. For these purpofes, the tool of this fort, which has lately been invented by Mr. Waifall, may also be found very ufeful in different cafes. See Turnip-He.

In whatever way the work may be performed, or whatever tool may be employed for the purpofe, it will always be of great utility to have the earth and mould well loosened near to the roots of the plants, when they are iff in any way, and to have all weeds well cleared out from about them.

Dangers to which exposed.—Turnip crops are liable to danger from different caufes during the more early ftages of the Growth of the plants, but the principal of them are thofe of the attacks of the fly, the flug, and the black caterpillar.

The fly chiefly preys upon the sweet tender feed-leaves of the young plants, and its preffure is rendered sufficiently evident by its leaving many little brown spots on them, and by its eating away their flehy green parts down to the fibres of the leaves. It is faid to increafe in fize, and the number to become larger, until the plants be wholly de-

froyed. It is fuppofed by fome, that from these infects being extremely numerous on fuch leaves of turnip plants, and not eating, but, as it were, fucking their sap or juice through long proboces or organs, that ferve to attach them to the leaves in somewhat the manner of leeches, they may, in fome measure, be the caufe of the very slow progrefs that is fometimes made in fuch plants to put into rough leaf.

The ravages of the flug are readily ascertained by looking to the edges of the leaves, as it begins firt to feed upon them, gradually afterwards proceeding from one part of them to another, until each is more or lefs consumed, fometimes exhibiting in the whole of the crop a partially eaten flate. In many cafes, almost the whole of the plants is destroyed.

The depredations of the black caterpillar mofly take place after the crops are in a more advanced flate of growth, and the plants have formed confiderable tops, and are in what is ufually termed rough leaf; the green parts of the plants being eaten through and deflroyed, consequently the growth of the plants greatly retarded.

A great many different practices have been proposed and had recourse to at different times, for guarding against the defftruction produced in these ways, but hitherto probably without any great success in eftectually preventing it. In this intention, the blending of new and old turnip-feed togethe, or fuch as has been moistified, and fuch as is dry, and uifing them as feed for raising the crops, has been ad-vised by fome, as by this means the plants, as crops, coming up at different times, may be lefs in danger of being wholly deffroyed, or may eflape in fufficient quantity for the purpofe, especially as fuch infects are well known to frequently make their attacks suddenly in large numbers, deflroying the plants as they rip, and as suddenly disappearing again, leaving those that come a few days afterwards untouched.

On the fuppoftion that other forts of plants are more defirable and liable to be fed upon by this defftructive infect than that of the turnip, the old practice of mixing and fowing other kinds of feeds with turnip-feed, as thole of the radifh and fome other forts, has lately been revived, and much extolled by different perfoas, but probably the method is extremely uncertain, as it cannot be fuccesful, except when the different kinds of plants rife pretty exactly at the fame time, which, from the great difference in the vege-tative powers of different feeds, will rarely be the cafe. Any ufe that can be gained in this way, must probably be by employing the feeds of fuch preferred plants, as are rather more quick in their proifuting and growth than thole of the turnip, as, where this is not the cafe, the turnip plants may often be deffroyed before the others are in a flate to be fed upon. The difting of the leaves of turnip crops over with caulfic juice in the flate of fine powder, has been tr.id, and found uifeful in faving them in fome cafes. The fame fubfance, as well as thole of vegetable alhes and foot in their reduced flates, when uifed by being thrown over the crops by the hand in pretty large quantities, have likewife occasionally been uifed with benefit against this infect as well as the flug. The sprinkling of tobacco-water, either fimpdy, or in mixture with fop-puds and urine by proper means upon the plants and land, has been found to deffroy the flags in a ready manner and to prevent their increafe. Heavy night-rolling has long been practiced with upposed succes against both the fly and the flug. And the practice of treating with sheep, by keeping them in conflant motion on lands cropped with turnips, as well as that of fowing barley-chaff over them, has been thought
thought useful against the latter. This last, as well as the tobacco mixture, has been tried with benefit against the black caterpillar, a huff-harrow being previously pulped over the crop to dislodge the insects. The harley-chaff is to be applied over the crop on their first appearance.

A great variety of other means has been proposed in these intentions, but probably with no very great success. See Black-Canker, Slug, and Turnip-Fly, Prevention of.

In turnip crops, the roots of the plants are liable to have a large fort of excrecence formed below the small apples or bulbs, which, after becoming in a state of something like maturity, takes on the putrid process, and tends for a most offensive smell. Plants in this condition are generally flung to in their growth, and the crops indifferent. It is laid to depend on soil, and that the soils of some turnip districts are subject to it until they have been clayed or marled, which is almost a certain remedy for this. It is the case with Norfolk; the soil is perhaps too light. The knobs often contain a small worm in the centres of them, which may be the cause. Taking out the affected plants and stirring the earth about the others may be useful. See Anbury.

On some thin light soils too, especially in dry seasons, these crops are sometimes liable to be affected with a fort of white mouldy blate, which injures and checks the growth of the young plants greatly; the chief means of removing which, is that of proper thinning and stirring the mould about the roots of the plants. When it occurs in deeper soils, benefit may be derived from rendering them more dry by deeper furrowing between the ridges. See Mildew.

Turnip-plants often hang off numerous thinning roots with knobby lumps at the ends of them, which are liable to decay and come to nothing, or what farmers term fringes, in the state of battling or forming bulbs. This mostly happens in new or fresh land, and with no mode of preventing it has probably yet been discovered. Utility in such cafes may, however, be derived from better tillage and preparation.

Where these crops have been destroyed by the fly, or in other ways, the same lands should not be resown without a flight ploughing, as it is too often the practice, as there must always be great danger of the crops of the second sowing in such cafes. It is better either to leave the land wholly for wheat, or to give a shallow ploughing or scuffling before the turnip-feed is again put in. Transplanting is laid to have been employed with benefit in such cafes, as the young turnip plant is found to succeed in this way.

The seafon most favourable to crops of this sort, are those in which the weather is warm and flowery, without much continued rain. In the autumn and winter periods, when the changes from frosts to thaws are frequent with rain, the roots are liable to much injury, by becoming decayed and rotten; and where they stand well in them, seldom afford the quantity of nourishment and support for flock that may be fed on them that is usual under other circumstances. They are liable too to be much hurt in the winter seafon by the wounds and punctures made in them by different forts of birds, as wood-pigeons, rooks, and some others; against which they should be guarded as much as possible.

The expenses of raising crops of this sort must necessarily vary considerably according to the nature of the soil, the crops which they succeed, the methods of putting them into the ground, the situation, and many other circumstances of different kinds; but in the ridge or drill practice, they may in many cafes stand in this way.

\[
\text{Total Expenses} = 5 10 4
\]

In the broad-cast practice, the expenses may modify perhaps a little lower than in the above estimate.

It is in most cafes the practice to sow barley after turnip crops, but in some northern districts, wheat, and other crops with seeds, are occasionally put in after them, when fed off with sheep, and cleared early and one ploughing.

The quantity of produce or food for flock which is afforded by crops of this sort, must, of course, differ much according to the differences of season, the nature of the soil, and the mode of culture that is pursued; but a medium crop, where the land is good and suited to the purpose, may afford fifteen tons or more on the acre; in many cafes, however, it will be much less. The value of such crops must depend upon many different circumstances, as their quality and abundance, the manner in which they can be consumed, as on the land, or in cribs and halls, in feeding or rearing live-flock of different sorts, and on the state of the market for the sale of such flock; but in common, it may be from about three or four to fix or seven pounds of the acre, and in some cafes considerably more, as ten and upwards. An acre of good turnips will fatten a beast of forty stone and more, or about eight sheep.

**Seedling Crops.** — In raising crops for feed, which is the produce of the second year's growth of the plant, considerable attention is necessary in the view of producing such as is good; as when it is collected from such crops as have been sown three or four years in succession, without transplanting, the roots are liable to be numerous and long, and the necks, or parts between the bulbs and leaves, coarse and thick; and when taken from such as have been transplanted every year, these parts are apt to become too fine, with too great a diminution of the tap-roots. The belt and moist certain way is, therefore, to take seed from turnip plants that have been transplanted one year, and sow the next; or transplanting once in three years is sufficient for preserving it good. The moist suitable manner of performing this is to select such turnips as are the hardest, the belt of their kinds, and that have the most perfect forms, from the common crops; and after cutting their tops off, to transplant or remove them, in the latter end of the autumn, into ground that has been well prepared for them, where birds can be kept off. The seed will become ready for gathering towards the close of the ensuing summer. Some prefer that the seeds taken from a few roots, transplanted in this manner, should be preferred and saved in the drill method, for the purpose of providing plants for affording feed for the general crops, taking out all such as are weak and improper, leaving only those that are strong, and which have the belt growth; and that when these have unripe, or formed bulbs, to again take out such as do not appear good and perfect; and, by this means, turnip-feed may be procured.
procured, which is not only of a more vigorous quality, but which is capable of vegerating with less moisture, and which produces stronger and more healthy plants, and, of course, better crops. The custom of transplanting the whole of the turnips in this intention is said to be too expensive, as well as injurious in some respects.

In either of these modes very good turnip-feed is capable of being railed and provided. When the feed, in these cases, is become fully ripe, the crops are mostly reaped by cutting part of the stems with the feed-pods upon them, afterwards tying them up into wads or sheaves, which, when properly dry, are carried and put into long narrow flacks, to be kept through the winter, and threfhed out near the time when wanted in the spring. As in this way, however, much feed is liable to be fed and lost, on account of its residuas to escape from the pods in which it is contained, it is probably a much better practice to have it immediately threfhed out, either upon a cloth in the place where it grew, or in some other more convenient spot, being then put into proper bags, and placed in a situation which is perfectly dry.

As crops of the feed kind are subject to injury and loss in many different ways, the quantity of produce must be different under different circumstances; but it may be said in common to be about twenty or twenty-four bushels on the acre. And as the price of turnip-feed is seldom less than seven or eight shillings the bushel, from the great demand for it, the culture may seem at first to be very beneficial; but from the exhausting nature of the crop, the loss in that of the grain, and the quantity of manure afterwards necessary, it is probable that turnips can only be fed with advantage in particular circumstances of soil and situation. As often as possible, however, the farmer should raise his own, as that of the shoppas is in general less to be depended upon.

**Application and Use of the Crop.**—The turnip is a plant or root that is capable of being made ufe of in different intentions, but the principal are those of feeding, supporting, and fattening different forts of live-flock, in which there are great differences in the practices of different districts of the kingdom; but the most economical and beneficial modes of applying and confuming it, under different circumstances of soils, situations, and animals, have probably not yet been sufficiently investigated and ascertained from what engaged in the cultivation of the root. It is flated by a practical writer, that though few trials have been made to determine the particular flatte or condition in which these roots afford the greatest and most suitable proportion of nourishment for different animals that are fed on them, it would seem, from their containing a much larger quantity of rich nutrient matter in their fresh flatte, before being taken from the ground, than afterwards when removed and packed up, as shewn by the shrinking and lofs of weight that takes place, to be a more saving and ufeful practice, particularly where the nature and situation of the land and feafon will admit of it, as on dry lands in moft of the southern parts of the country, to confume them under the former rather than the latter circumstances; but in more cold and expofed situations, as in many places in the northern districts of the kingdom, and wherever the lands are inclined to moiture or heaviness, as the roots may be greatly injured by frosts and other causes, and the animals receive much harm from the coldness of such places, while feeding on them, as well as the lands be much damaged by their treading, it may be better to eat them under the latter conditions. There are likewise other situations and circumstances, it is supposèd, in which it may be particularly necessary, as well as bene-

**TURNIP.**

Wherever crops of this sort are, however, taken from the land, to be consumed by animals in other places, as from their nature and large growth they must exhaust and deprive it of its fertility greatly, it will conffantly be proper and necessary to return an equivalent in manure, otherwise the harm done in this way may more than equal the benefits of the crop. And in all such cases, the tap-roots and other waste parts should always be removed and left on the land, that neither foil nor manure may be taken away, by adhering to them.

In cases where the lands are properly dry, in a high state of fertility, and under good management, it may often too be an advantageous and economical practice to have a partial recourse to both the methods, by having one part of the crop drawn, removed, and eaten off the land, in some adjoining convenient place for the purpose, and the other fed off on the field where they grow; as, by such means, a much larger quantity of land may be benefitted and improved, without injury to the crops that may afterwards be grown on the turnip land.

In this mode of improving lands, a great deal more is yet probably capable of being done than has hitherto been the case, when its vail utility and powers in different ways are fully considered.

Some difference in the ufe and manner of confuming this fort of crop likewise takes place, from the kind of flock to which it is applied; as when used in the rearing, keeping, and fattening neat-cattle flock, it is, for the most part, pulled up and eaten, either or having been removed to some proper dry field or spot of ground of the graps or flable kind, or to some feld or other building near the straw-yard or feeding-house; in the latter case, being given the flock in bins, troughs, or cribs, or placed before the heads of the cattle in flats, when tied up, that are contrivèd for the purpose. The latter of these two modes of eating the root is supposèd the better, though lefs frequently made ufe of, as there is the lealf possible waste, while, at the fame time, the dung and urine of the cattle are the most extensively and effectually confumed. In the former of these methods, the usual practice is firft to admit the fattening flock, and then to allow the lean to follow them, and cut up what may remain. In this way there is the lealf loss.

The cattle are mostf frequently used when the roots, except when prevented by the state of the feafon, when they are confumed in other places, or as above. In some cases, the lands to which the roots are removed, in this method of feeding, are those intended to be used for other crops in the ensuing year, by which the different fields, of course, in their turn, have the benefit of being improved in this way moft conveniently; and the practice is found more ufeful than feeding them on the land where they grow. The roots, in these cases and modes of confuming them, should not be scattered over the ground in too thick a manner; as, where that is the case, much lofs mutt necfarily be fustained by their being crushed and bruised by the feet of the flock, while upon them.

Thfe several different practices are much had recourse to in fome southern turnip districts, where great numbers of different forts of this kind of flock are every year fattened on turnips.

In cases where milk is a principal object with the farmer, this plant and root are also capable of great ufe as a proper juicy food for cows, care being taken that the decayed

\[N\]
leaves and other parts be not given, as they are apt to communicate a disagreeable flavour to it. The offal produced in such cafes may be given to the dry flock, by which little or no loss will be sustained in the consumption of the root. This taste in milk is said to be completely removed by the use of a very weak solution of nitre in water.

These roots, too, have been usefully applied in the feeding of work-horses, as by their means the usual quantity of corn may, it is said, be lessened nearly one-half, and the horses rife in condition at the same time, as well as perform their labour equally well, and be more free from bowel complaints than in the common manner of feeding them. When used in this way, they should, however, be chopped, and have dry food of some sort joined with them in proper quantity.

The most extensive use and application of this crop is, however, in its consumption by sheep, particularly where the more suitable improved fats prevail, in which the most general practice, where the lands are properly light and dry for the purpose, is that of confining them upon a suitable proportion of the crop by hurdles, or other means, and removing them to fresh parts, portions, or breaks, as they are sometimes called, every eight or ten days, or oftener, according to circumstances, or as the spaces may be eaten and cleared by the flock. Where the crop is used as that of corn, the former bands, the former confined in this way, and the latter left at liberty, as feeding more readily in this manner. But where the soils are of a more deep and heavy retentive quality, it is more usual, and a better and more beneficial method, to have the roots drawn and removed, as wanted, to some adjoining field to be conserved by the sheep, somewhat in the way noticed for cattle; as, in this manner, there is not only less injury and waste by feeding and treading the turnips into the ground, but the sheep get a more certain and regular supply of fresh roots, by which they do better, and the shales, being kept clean, are more fully and completely eaten up by the flock cattle that are afterwards put upon them for the purpose. In some cafes and flats of the land too, in the former mode, it is the practice to have the crop partly eaten off on the land on which the turnips grow by sheep, and partly drawn and removed, to be conserved in other places. In such cafes, the method is usually to turn the sheep upon them as they stand in the field; but, except the bulbs be much exposed above the soil of the land, it is probably a better practice to have the roots pulled up on the ground before they are turned in and confined on it, as in this way they are not only less apt to break and fill the turnips, but feed and fatten much better upon them. This practice is much in use in some southern districts.

In some situations, the hilly parts have the turnips fed off in this manner by sheep, with a certain quantity of hay allowed for every acre thus eaten off, beginning with a break or portion from the lowest part of the field, and allowing a new portion or break every day, still gradually rising, clearing the whole off in time for preparing the land for the following crop. The crops on the more flat and heavy parts of the lands are drawn and removed, to be eaten with hay or other dry food in proper places.

It has been suggested, that much loss is often sustained in these modes of feeding off turnips by folding sheep upon them, particularly where the crops are raised in the broad-cut manner, and it is the custom to give the sheep large felds or breaks at a time, in confluence of frost or snow taking place. In such cafes, it is supposed, the ridge or drill method is far preferable, as it is easy to have the pens or trays made and fixed in such a manner as to constitute a fort of moveable crib or trough, the bars being set near the

fides of the rows, and the boards from ten to twelve inches in breadth, having flakes of suitable lengths, as the depth of the foils may be, nailed to them, and secured on the fides from which the sheep feed. The narrower the spaces the turnips are included in, the better. As it may be imagined that the animals may get in among the turnips so fenced off, it is said that, supposing the roots may occupy a regular space of about twelve inches, the troughs may be made little more than a foot in width at the bottom, having a flopping direction upwards. The bars may likewise have an inclination towards the sheep, and hang over the troughs or the parts in which the turnips are inclosed, and thus prevent them from getting in. It is supposed that in this way the sheep will have their food quite clean, and that by setting off only at a time the quantity necessaary for a day, they may eat it with more avidity, and without the danger of spoiling so much by their discharges, as is moaily the case in the common circumstances of feeding upon the root.

On examination, it is contended that this mode, when even largely employed, will be found to be better in many respects, as well as a great deal cheaper, as, on the most moderate calculation, three sheep may be kept in this way to two by the common old method, or perhaps even double the number, and they will fatten much sooner. And on the other side of the account, this last time may be turned into the advantage of the inhabitants, as it is thought that if the sheep, in such cafes, were driven into the straw-yards for the night, and even to eat straw in the morning, they would retain the turnips longer, and fatten quicker; while, in the mean time, the persons employed in looking after them might move the hurdles a row further, and thus little time be lost. If both fattening and f more sheep should be kept in this manner, it would be proper to give the feeding flock rather more roots than are sufficient for the day, and to turn in the f more sheep the succeeding day to consume what may be left. In this mode, the length of turnips that may be necessary, without wasting being committed, may soon be discovered. It would seem, however, that from the constant trouble, difficulty, and expense of the plan, in providing hursles, and fixing them for the folds, they would render it incapable of being put in execution, except in cafes of a small number of sheep, where it may be an improvement, and a more economical manner of feeding off turnips crops by such forts of flocks.

In the practice of feeding off this purpose, great attention is necessary to see that the hurdles are at first well let into the ground, and secured by flakes of sufficient length, with proper withs for tying them together, as after frosts and thaws, or snows, they are very apt to be thrown down by the wind, and other causes. The beft fort of hurdles for this use is that of the flatted kind; and a material of the netting kind is sometimes employed, which is called tailings, but it is more expensive. See Hurdle.

In whatever manner the feeding off turnips by sheep is done, the hurdles should always be set in such directions and forms, as that labour and expense may be saved as much as possible.

In some districts, the practice of feeding off these crops in a partial manner, or that of pull and throw, has given way to that of consuming them wholly upon the land, from the full conviction of its greater utility and profit; while in others, the mixed method of eating the root is still had recourse to, as being preferable for the purpose, and affording more benefit.

As it is found, in the fattening of sheep on this crop, that they make the greatest progress just before the turnips begin to run and form their feed-items, which is supposed
The only perfectly secure mode would be that, probably, of having them drawn, topped, and piled up with layers of dry straw in houfes properly formed and constructed for the purpose, and conveniently situated for the sheds and other feeding places; but it would be liable to objection, except on a small scale, as being both troublesome and expensive.

A method of preferring this root, which is much in use, very effectual, little expensive, and attended with no great trouble, is that of drawing and piling the turnips up in different portions on the field where they are raising, with layers of dry straw put between each of thofe of the turnips. In this mode, which is much practifed in fome fouthern counties, a load of straw is used to about thirty or forty tons of the turnips. The manner of effecting the work is faid to be this: the turnips, on being drawn in a dry time, and the tops and tap-roots removed, a layer of straw is spread out on a dry part of the ground, and a layer of turnips placed upon it to the thicknefs of eighteen inches or two feet; after this another layer of straw, and then a layer of turnips; proceeding on, alternately in the fame manner, until the pile or heap be brought to a fort of ridge or point; when the edges of the different layers of straw are turned up and fainted, which ferves to prevent the roots from falling out, and at the fame time affords a fort of external covering to the heap or pile, which is completed by well thatched over the top with long straw.

It is fuppofed too, by fome, that the difficulty of getting them out of the ground, and the dangers they are exposed to in fevere froifty feafons, as well as the inconvience the flock experience in feeding upon them from their coldnefs, and the hazard of their injuring the land by remaining too long, may all be avoided by piling them up in a familiar manner, in small heaps in the flack form, the tops outwards, near to the places in which they are to be confined, covering them over with waffles or hurdles lined with straw.

In fome cafes, turnips have been attempted to be preferred by being formed, without straw, after the tops and small roots have been taken off, and the former used green, into a fort of heaps termed pier, in the manner in which potatoes are sometimes kept, being well thatched over on the outsides by straw or fome other more cheap material.

They have been attempted to be preferred in the field by covering them by deep ploughing in different manners, when perfectly dry.

A great many other modes of preferring these roots have likewise been fugged and practifed by farmers and others, but they need not be noticed here, as they moftly appear lefs ufeful than the above.

In all cafes of preferring these roots in the heap manner, care must be taken not to have them made too large, or too confantly packed up together, as the danger of their heating and being spoiled, may thereby be, in a great meafure, avoided.

By fome means of these forts, turnips may moftly be preferred, kept ready, and fit for ufe as food for live-flock, even in situations and feafons which are the moft exposed and severe, which under different circumstances are often matters of much confequence to farmers. See TURNIP, supra.

TURNIP, Swedish. See RUTA BAGA.

TURNIP, Stubble. See STUMBLE-TURNIPS.

TURNIP-Cutter, or Slicer and Chopper, contrivances of the cutting kind, which are made ufe of in preparing this fort of root for being eaten by different kinds of live-flock. Implements of this nature are formed and constructed on very different
different principles, but those which have the greatest simplicity are almost always to be preferred, as performing the work in the most easy and ready manner. There is a very useful tool for this purpose, in which the roots are cut by means of a knife fixed upon a fly-wheel, the turnips being forced upon it through an inclined hopper or fort of trough. Some turnip-slicers are so effective as to cut a bushel of the root in a minute.

The chopper is made by a fort of sharp small spade, either fixed or loose, working in a box, into which the roots are thrown for being cut or chopped. The work is readily executed in this way by those who are in the habit of performing it in this manner.

**Turnip-Drill**, that fort of drilling implement which is employed in the fowing of turnip-feed in the row manner. An improved tool of this fort for one-bout ridges is in use in some districts, which obviates the defects of fowing too much or too little feed. It consists of a solid cylinder, made of iron or brass, about two inches in diameter, and one inch broad, on the surface of which are formed fifteen or sixteen cavities, resembling the shape of a semi-egg when cut longitudinally, and as deep as to hold four or five feeds each. On the back of the cylinder a little from the top, is placed the hind part of the hopper, to which is fixed a piece of iron or brass, one inch long and half an inch broad, hollowed on the inside in the form of a Gothic arch, the sides of which meeting the sides of the cavities in an oblique angle, prevent the feed from being bruised; at the lower end of this piece of iron, or gatherer, there is a slit, three-tenths of an inch long and one-tenth wide; and at the back of it, a thin flat piece of iron moves up and down by means of a ferew at the top of the hopper, which enlarges or lessens the orifice directly above the cavities, and increaseth or diminiseth the quantity of feed delivered, as the workman may think proper. This slip of iron, or regulator, is let into a groove made in the board, which forms the back-part of the hopper. The cylinder is fixed, before the cavities are made, on an iron axle one inch square, turned very true, as well as those parts of the axle which turn in the collars fixed in the handles. To the ends of the axle are fixed two wheels, twenty-six inches in diameter, which turn the axle and cylinder round, and which, in passing through the hopper containing the feed, bring forward in each cavity a number of feeds and drop them into the spout, by which means they are conveyed to the couler, which forms a rut or channel on the top of the one-bout ridge in order to receive them. If the cavities in this fowing implement be made to hold five feeds, when the regulator is ferewed close down, and there be sixteen of them, it will deposit eighty feeds each revolution; and from the diameter of the wheels being twenty-six, and the circumference eighty-one inches and a half, eighty feeds will be fown in eighty-one and a half inches, or nearly twelve feet. This being the minimum quantity, by screwing up the regulator, the number may be increaseth gradually to fifty or sixty in a foot, which is far more than is necessary in almost any cafe.

There are various other improved implements of this nature, which suit different purpoeses of this fort of culture made use of in different circumstances and places. See Dril and Turnip.

**Turnip-Hoe**, a hoe employed in the culture of turnips, which is of the hand as well as the horse kind: the latter is the most ready and effectual, but both are frequently made use of in raising the crops.

A turnip-hoe chopper has lately been contrived, which is both useful in this way and for cutting the roots in feeding flock on the land. It has in the first part the make of the common nine-inch hand-hoe, but forming an oblong square, with an eye to receive the handle from the centre of the first part or hoe, another crosses it at right angles, but this second is not made solid, as in the first common one, but, like the Dutch-hoe, the centre part is open the whole length of it. In working, the turnip being pulled out of the ground by the angles of the hoe, is immediately struck with the centre, which divides it into four pieces, and if these be not small enough, the stroke is repeated upon each of the pieces until they be sufficiently so. It is imagined capable of much improvement, by having two floutith prongs on the back or reverfe part of the hoe, proceeding from the neck of the eye; these prongs would pull up the turnips with a great deal more expedition, it is suppoled, and the increased weight of the hoe would rather be in its favour, by stiffening the force necery to split the roots. The whole is simple and the expence trifling, which render it more valuable.

It is said that by means of this tool the turnips may each readily be fliccd into as many parts, according to their sizes, as that each piece may be small enough for wether lambs, or, which is of more conuenience, for being eaten by the crows, or old toofplews ewes, which may hatch out this way, with nearly equal facility as the young sheep, as they are capable of picking them up, and by a slight toss of the head, to place them so as to be properly conformed. They can thus feed on the root, when they would otherwife find it difficult to supply themselves with a sufficient quantity of food in the usual manner of nibbling the turnip, either while in the ground, or when picked up without being cut. It is the invention of Mr. Malcolm, and is in much use in the county of Surrey, and may be beneficial in many other districts, where the practice of feeding off the crops on the land by flock is a material object to the farmer.

Hand-hoes of from four to twelve inches in width are in use, in this kind of culture, for fetting out the plants and other purpooses, as the nature of the crops may be. See Hoe and Turnip.

**Turnip-Rack**, a contrivance of the rack kind, for sheep eating this and some other sorts of food out of with less waife than in some other ways. It is usually made about eight and a half feet long, and on one side two feet high, and on the other two feet three inches, without the feet, which are about three inches long. In the top, the middle part folds back on the rack, and on the lower part or side of it there is a bend, which serves as a gutter for preventing the rain-water falling from it on the sheep's back. The bottom opens the other way and leaves against the ground, for the convenience of carrying it. It is sometimes placed on low wheels. It is very useful and convenient in many cafes of feeding and fattening sheep.

**Turnip-Sowing Trough**, a contrivance of this kind for the purpose of fowing turnip-feed with regularity in the broad-call manner, where it cannot be done by the hand. It is somewhat in the box form, and fo conformed as to difperfe fuch small feeds with great exactness over the land. See Turnip.

**Turnip-Tray**, a long narrow shallow fort of trough or box contrived and made use of for the purpose of sheep eating turnips out of in confuming them upon the land, in order to prevent waife in fuch modes of feeding.

**Turnip-Roasted Cabbage**, See Cabbage.

**Turnip-Roasted Celery**, a root of that fort of the turnip form. See Apium.

**Turnip-Fallow**, in Agriculture, a term applied to that fort of preparation for the crop which is made by repeatedly working
working over the land in some way or other. The most improved practice is that of not having the autumn broken-up lands tilled again, until the surface-working in the early spring has well loosened the mould, to favour the growth of weeds, which is best performed by means of tools that operate the more superficially, as by this tillage keeping the upper parts fine and unburied that have been broken and reduced by the plough, it is more suited to the rising of such plants than that of turning it down in a deep manner, and the work is done with greater expedition, which is a material object at such a season. This is a most excellent method; but much must constantly depend on the nature and state of the land in such sorts of work. See Fallowing and Turnip.

Turnip-Fly, Prevention of, the means of guarding and protecting young feeding turnip-plants against its attacks and ravages. Though many different means of this nature have been proposed, few have been attended with much success in preferring the crops. The substances which appear to be the most promising in this intention, are those of foot and quick-time, and urine, and quick-time, in a state of mixture proper for being thrown over the plants on the land, in a watering manner, by some form of contrivance for the purpose, or for being put in with the feed. It is suppos'd that the volatile alkali which is given off by these mixtures, may be offensive to the insects; whilst at the same time they afford nourishment and readiness growth to the plants. In a trial with lime flaked in urine, in mixture with three parts of foot, applied by means of a small barrel, perforated all round with little gimlet holes, so as to let the quantity of about four bushels to the acre pass out, and fall into the drills with the turnip-seed, the adjoining rows were found to be eaten away, while those to which the composition was applied were scarcely touched at all. The mixture of sulphur with lime has been used, but on a full trial found wholly inefficient. Ammonial fumes are said to be efficacious by some, but further trials are wanted, and they are not very well suited for the farmer's purpose. See Seed, Steeping, and Turnip.

TURNITZ, or Turnonice, in Geography, a town of Moravia, in the circle of Brunn; 30 miles S.S.E. of Brunn.

TURNNO VICECOMITUM, in Law, a writ that lies for those that are called to the sheriff's turn, out of their own hundred.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, wagons, coaches, &c. to take toll of them, or money towards repairing or keeping the roads in repair. See Road.

There are several statutes, which have established regulations relating to turnpike-roads, the principal of which, besides those recited under Highway, are as follow. No person shall be capable of acting as a trustee in superintending turnpike-roads, who is not possessed of lands, &c. of the clear yearly value of 40l, or personal estate to the value of 800l; to which purpose he makes oath before two trustees, or their apparent of a person possessed of an estate in land of the clear yearly value of 80l. No alehouse-keeper, nor persons retailing liquors of any kind, are capable of acting as trustees, or holding any place under them, or collecting the toll; but they are not precluded from farming the tolls, provided some other person collects them. No gate-keeper, or person renting the tolls, and refunding in the toll-house, shall gain a personal settlement, nor shall the tolls, or toll-house, be assessed to the poor-rate, or any other public or parishal levy. Any gate-keeper, permitting a violation of the orders pertaining to carriages and horses, and not proceeding with

in one week for the recovery of forfeitures, shall forfeit 40l. and both he and the surveyor shall render upon oath, when required by written notice from the trustees, an account of all money received, on pain of 5l; and all officers shall deliver up their books, &c. relating to the execution of their offices, within ten days after written notice, on pain of 20l; and all persons concerned in the execution of acts relating to turnpike-roads, neglecting their duty, shall forfeit 10l. The Trustees, whole meetings are assembled by ten days' notice affixed on the toll-gates, or other conspicuous places, and adjourned for no longer time than three calendar months, or any five of them, may cause weighing-engines to be erected at the toll-gates, order the weighing of carriages and their loads, and take an additional toll for every hundred weight, over and above the following weights: 2½. for every four-wheel carriage, having the fellies of the wheels sixteen inches broad, eight tons in summer, and seven in winter; for every wagon and wain, with axles of different lengths, having the distance of the nearer pair of wheels on the ground not more than four feet two inches, and the distance of the other pair such, that the fore and hind wheels shall roll only a single surface sixteen inches wide, at the leaf, on each side of the carriage, and the fellies nine inches from side to side, fix tons ten hundred in summer, and fix tons in winter: for every four-wheeled carriage, having the fellies of the wheels nine inches broad, fix tons in summer, and five tons ten hundred in winter: for every cart, having fellies of nine inches, three tons in summer, and two tons fifteen hundred in winter: for every wagon, having the fellies of the wheels fix inches broad, four tons five hundred in summer, and three tons fifteen hundred in winter: for every wagon, rolling a surface of eleven inches, five tons ten hundred in summer, and five tons in winter: for every cart of the same dimensions, two tons twelve hundred in summer, and two tons seven hundred in winter: for every wagon, having the bottom of the fellies of the wheels of breadth than fix inches, three tons ten hundred in summer, and three tons in winter: and for every cart of the same dimensions, one ton ten hundred in summer, and one ton seven hundred in winter: fummers, in all these cases, being determined from May 1, to October 31; and winter from November 1, to April 30. (13 Geo. III. c. 84.) The additional toll shall be as follows: 2½. for the first and second hundred of over-weight, the sum of 3½. for each hundred: for every hundred above two, and not exceeding five hundred, 6½.: for every hundred above five, and not exceeding ten hundred, 2½. 6d.: for every hundred above ten, and not exceeding fifteen hundred, 5l.: and for every hundred above fifteen hundred, 20l. The Trustees, however, of the several turnpike-roads within ten miles of London, Westminster, and Southwark, are allowed to lower these additional tolls at pleasure. (14 Geo. III. c. 82.) The toll-taker offending against these regulations, incurs a forfeiture of 5l; but the preceding regulations of weight do not extend to any carriage employed in husbandry, and carrying manure for land, hay, straw, fodder, or corn unthreshed; excepting hay or straw carried for sale; nor shall any toll be taken for horses belonging to officers or soldiers upon their march, or upon duty, or for any horses, cattle, or carriages, employed in carrying their arms or baggage, &c. It is required that a table of the several tolls be put up at every toll-gate. (18 Geo. III. c. 63.) For the encouragement of broad wheels, the Trustees are empowered to reduce the toll of carriages, having wheels six inches broad, so that it may not be greater than that which is taken for four-wheeled carriages drawn by four horses; and for carts, having the fellies of their wheels six inches broad, no more than for carts drawn by.
by three horses; but for every carriage, having the fellies of the wheels of less breadth than six inches at the bottom, and for the horses, &c. one-half more than the toll payable for the same respectively, except carriages carrying corn in the straw, hay, straw, fodder, dung, lime for the improvement of land, or other manure, and implements of husbandry. The fellies of the wheels of carriages entitled to the above exemptions, and the tire upon them, are required to be so flat, as not to deviate more than one inch from a flat surface. And all carriages, moving upon rollers sixteen inches broad on each side, with flat surfaces, shall pay only so much toll as shall not exceed half of the full toll payable for carriages having the fellies of the wheels six inches broad, and not rolling a surface of sixteen inches on each side; and half-toll shall be paid for waggons having the fellies of the wheels nine inches broad, and rolling a surface of sixteen inches on each side. These regulations do not extend to any chaise-marine, coach, landau, berlin, chariot, chaise, chair, calash, or hearse; nor to the carriage of ammunition or artillery for his majesty's service; nor to any carriage drawn by one horse, or two oxen; nor to any carriage having the fellies of the wheels nine inches broad, and laden with one block of stone or marble, one cable-robe, and one piece of metal or timber; and no toll shall be paid at any turnpike-gate for carriages employed in carrying materials for the repair of any turnpike-road, or public highway. No four-wheeled carriage, having the fellies of the wheels of less breadth than six inches, shall pass on any turnpike-road with more than four horses. Two oxen or neat cattle shall be considered as one horse. For other regulations relating to the number of horses, see Highway. Any carriage may be drawn with any number of horses upon a turnpike-road, where a weighing-engine shall be erected, provided the carriage be weighed at such engine; and the trustees may allow for hills, the rise of which shall be more than four inches in a yard, such number of horses as they shall think necessary, not exceeding ten for waggons with nine-inch wheels, nor fix for carts with nine-inch wheels; and not exceeding seven for waggons with five-inch wheels, nor five for carts with five-inch wheels; and not exceeding five for waggons with wheels of less breadth than six inches, nor four for carts of such dimensions. There is also an exception in favour of carriages that are drawn in deep snow or ice. No carriages, with the fellies of the wheels of less breadth than nine inches, shall be allowed to pass upon any turnpike-road, if the same shall be drawn by horses in pairs; except such, having the breadth of the fellies fix inches, authorized by seven or more trustees, and carriages drawn by two horses only. The penalty, on conviction, by confession or oath of one witnies, is a forfeiture not exceeding 3l. nor less than 10s. The penalty on evading the tolls, by unloading goods, is 3s.; by turning out of the road, for the owner, any fum not exceeding 3l. nor less than 20s.: but for the driver, if he be not the owner, any fum not exceeding 50s. nor less than 10s.; by taking out horses, 5l.; or by taking the benefit of any exemptions fraudulently, a sum not exceeding 3l. nor less than 40s. Exemptions in favour of cattle going to or from water, or pails, shall extend only to such as shall be driven from one parth to the next adjoining, or that shall not pass upon the turnpike-road more than the space of two miles. Turnpike roads are kept in repair by the statute-duty, required by the severall acts, or if this be insufficient, by contracting for labour, &c. The surveyor of any turnpike-road, who shall suffer to remain in any part, within ten feet on either side of the middle of it, for four days, any heap of stones, rubbish, &c. obstructing the passage of it, shall forfeit 40s.; and any person encroaching on it by a ditch, fence, &c. shall forfeit 40s.; and the trustees may direct prosecution by indictment for any nuisance, at the expense of the tolls. See Highway and Road.

If any person shall wilfully or maliciously destroy any turnpike-gate, poll, rail, wall, chain, bar, or other fence, set up to prevent passengers from passing without paying toll, or any house erected for the use of such gate, or any weighing-engine, or refuse any person in custody for such offences, he shall be found guilty of felony, and transported for seven years, or committed to prison for any time not exceeding three years. The indictment for such offences may be inquired of, heard, and determined in any adjacent county; and the hundred shall answer damages, as in cases of robbery. If the trustees erect a gate where they have no power, the justices upon complaint may order the sheriff to remove it. As for direction-tolls, &c. see Highway.

The trustees are empowered to let the tolls to farm, in consequence of public notice, to the best bidder; and if the farmer of the tolls shall take a greater or less toll than he ought to do, he shall forfeit 5l. and the contract; and every other gate-keeper, offending in the same way, shall forfeit 40s. The trustees may also let the tolls during such time as they shall think proper, provided that the persons entitled to five-sixths of the money remaining due upon such tolls content. The penalty for obstructing the execution of any turnpike-act is a forfeiture of a sum not exceeding 10l. nor less than 40s. to be paid to the surveyor for the use of the road, or commitment to the common gaol, or house of correction, for any time not exceeding three months, unless the money be sooner paid. Persons aggrieved by proceedings in the execution of turnpike-acts may appeal, with previous notice, to the general quarter-fellions, when the justices shall determine the appeal, and award costs, &c. But all actions are limited to thirty-three calendar months after the fact committed, and to the county where the defendant resides, or the fact was done; and the defendant may plead the general issue, and if he prevails in the action, have treble costs. 13 Geo. III. c. 84. 14 Geo. III. c. 87. 16 Geo. III. c. 39. 17 Geo. III. c. 16. 18 Geo. III. c. 28. c. 63. Burn's Justice, art. Highway.

The first turnpike-road erected by law was A.D. 1663. 16 Car. II. c. 1.

Turnpike is also used, in the Military Art, for a beam fuch full of spikes, to be placed in a gap, a breach, or at the entrance of a camp, to keep off an enemy. See Cheval de frite.

TURNSOLE. See TURNESOIE.

TURNSIT, VERSATOR, in Zoology, a variety of the dag (which see), which belonged, in the arrangement of Dr. Caius, to the clafs of degeneres, curs, or mongrels.

This breed is much on the decline in England; though still used in some other countries.

TURNSTONE, in Ornithology, the English name of a bird, the tringa marinella of Linnaeus, called by authors marinella marina, or sea-dotteder.

It is a little larger than the blackbird; its head moderately thick; and its body of a length that its back and wing. Its length long, thick and whitish at the base, and sharp and black at the point; and its head, neck, shoulders, wings, and the upper part of its breast, are of a brownish colour: its throat and forehead are ash-coloured; the back and rump are white; the middle of its back is marked with a very large triangular black spot; the tail confines of twelve feathers, the lower half white, the upper black, and the tips white; the quill-feathers are dusky, but from the third or fourth the bottoms are white, increasing to about the ninetneth, when the
the feathers are entirely of that colour. Its legs are short, and of a reddish-yellow or orange-colour.

These birds take their name from their method of feasting. In the act of swallowing, they turn up small flumes with their strong bills, to get at the insects that lurk under them. Ray and Pennant.

Mr. Pennant mentions another species, which is the turn stone from Hudson's Bay, and the *tringa interpres* of Linnaeus; often shot in the north of Scotland and its islands, and also in North America. This bird is of the size of a thrush; the forehead, throat, and belly are white; the breast black; the neck surrounded with a black collar, whence another bounds the sides of the neck, and paffes over the forehead; the head and lower part of the neck behind white; the first streaked with dark lines; the back ferruginous, mixed with black; the coverts of the tail white, crossed with a black bar; the tail black, tip with white; and legs rather short, and of a full orange.

TURN-UP COMPASSES. See COMPASSES.

TURNWRIGHT PLOUGH. See PLOUGH.

TURO, in Geography, a town of Naples, in the province of Bari; 22 miles S.S.W. of Converano.

TUROE, a small island of Denmark, in the Little Belt; 12 miles S.W. of Aarhus, in the island of Funen.

TUROK, a mountain of Persia, in Khorassan; 15 miles S. of Mefchid.

TURON, a sea-port town of Cochinchina, in a bay to which it gives name, and which is deeply indented, so as to afford shelter in some or other of its inlets from every blast of wind; the bottom is mud, and the anchorage safe, with a smooth water throughout. N. lat. 16° 5'. E. long. 108° 6'.

As this harbour affords a safe retreat for ships of any burthen, during the most tempestuous feasons of the year, Mr. Barrow undertook to draw a plan of it agreeably to geometrical admeasurement. The particulars of the operation and its result are described in Macartney's Embassy to China, and minutely illustrated by means of a chart. This chart exhibits an irregular mountainous peninsula, inaccessible on every part of the coast, except that adjacent to the harbour, and at two small sandy bays in the entrance. This peninsula was named New Gibraltar, on account of the local natural advantages which it possesseth, and which renders it capable of being made, like our Gibraltar, impregnable. The natives call this peninsula *Tien-tcha*. United to this peninsula is a level isthmus, from three-quarters of a mile to a mile in width, containing several small villages and patches of ground, under cultivation, chiefly of rice, tobacco, pulse, and fugar-canes. The chart presents also to view the principal town in the vicinity of the harbour, at which the market is held: the adjoining land is well cultivated; and the name given to the place by the natives, as well as to the harbour, is Han-fan. Connected with the peninsula by a reef of rocks, unobserved at low water, is the northern point of a small island clothed with trees and thick bruwash; and as the depth of water is three fathoms within a ship's length of the southern extremity of the island, a convenient place might be prepared, at a small expence, for heaving down and repairing ships. The rocks might be the foundation of a pier or caufway, and thus an excellent dock might be constructed between the island and this peninsula. Such a place would be well adapted for a repository of naval flores, magazines, or warehoufes.

The appendages to this harbour are described and represented in the chart; and particularly a valley with a small village, and about forty or fifty acres of land under tillage, mostly bearing rice; a large village on the banks of a considerable river, meandering through an extensive and apparently fertile and plentiful valley, a cove with plenty of water for ships of any burthen, good anchoring ground, well sheltered, especially from the north-east monfoon, and having at its head an extensive plain, with two villages separated by a small running stream, with forty or fifty acres employed in the culture of rice; and a group of curious marble rocks, extending across the isthmus, one end being washed by the sea, and the other end of the river, without exchanging the river. The adjacent country is suppos'd to be in general, healthy, the violent heat of the summer months being tempered by regular breezes from the sea. September, October, and November, are the feaon of rains; which are also frequent in December, January, and February, attended at this time by cold northerly winds. The inundations, which take place, generally, once a fortnight, and last two or three days at a time, have an effect similar to that of the periodical overflows of the Nile, in rendering the country one of the most fruitful of the globe. In many parts, the land produced three crops of grain in the year. Its most valuable produce, besides the precious metals, confitiled in pepper, cinnamon, fugar, filk, and cotton, which the natives give in exchange for a variety of European manufactures. Not far from the harbour of Turon is the town of Fai-foo, a place of some note, and about eight miles E. of the mouth of a considerable river on the coast of Cochinchina, on the banks of which lies Fai-foo; and opposite to the said mouth of the river is Callao, or, as the Europeans call it, Campello, the bearing of its hightest peak from the harbour of Turon being about S.E., and the distance from it thirty miles. Stausont Emb. to China, vol. i. See Callao.

TURONES, or TURONI, in Ancient Geography, a people of Gaul, described by Lucan (i. i. v. 437.) under the epithet of unfable.

"In tabiles Turonea circumsita caldra coerent.

According to Ptolemy, they had a town, which he calls "Cesaradunum," and he names the people "Turupii." Their city was situated in the mid of the Loire, and they inhabited the territory that lay to the N.W. of it, and belonged to the third Lyonne, of which their city became the metropolis. They had the character of not being fond of war: Tacitus calls them "Turonii imbelle," and Sidonius Apollinaris says of them, "bella timentes defended Turones." When the Roman empire was destroyed in Gaul, the Visigoths became masters of this city under the reign of Euric, and it belonged to them under that of his son Alaric in the year 506. But Clovis, having vanquished and killed this prince in 507, took possession of the whole territory from the Loire to the Pyrenées, and also of the city of Turon, the name of which has been since changed to that of Tours; which fo.

TURONILLA, in Ichthyology, a name given by some authors to the common little prickly fish called the stick-back, or barnflickle.

TUROOT, in Geography, a town of Hindoostan, in Lahore; 25 miles S.E. of Jummo.

TUROQUA, in Ancient Geography, a town of Spain, on the route from Bracara to Alturica, between Burbias and Augus Celtinus. Anton. Itin.

TUROWLA, in Geography, a town of Poland; 20 miles S.E. of Ploczkow.

TURPE, a town of Welshphalia, in the bishopric of Padruh; 3 miles S.E. of Salzkotten.

TURPENTINE, TURBENTHIA, a transparent fluid of resinous juice, flowing either naturally, or by incision, from several unctuous and resinous trees: as the turbarthia, larch, pine, fir, &c.

Medical writers differ in the kinds of turpentine ; as
TURPENTINE.

That of Chio, or Cyprus, that of Venice, that of Strafburg, and the common turpentine.

The turpentine of Chio, or Cyprus, which is the finest genuine kind, and that which gives the denomination to all the rest, is generally about the composition of thick honey, very tenacious, clear, and almost transparent, of a white colour, with a call of yellow, and frequently of blue, of a warm, pungent, bitterish tafe, and a fragrant smell, more agreeable than that of any of the other turpentines.

This is the produce of the common terebinth, or pistacia terebinthus of Linnaeus (see Pistacia), an evergreen bacciferous tree or thorn, growing spontaneously in the Eastern countries, and in some of the southern parts of Europe. The turpentine brought to us is extracted in the islands whose name it bears, by wounding the trunk and branches a little after the buds have come forth; the juice is thin and clear as water, and by degrees thickens into the confiidence in which we meet with it. A like juice, exuding from this tree in the East, infiltrated by a flow fire, is used by Kempter to be used as a medicinal by the Turkish women, for preferring the teeth, sweetening the breath, and promoting the appetite.

The turpentine of Venice is usually thinner than any of the other sorts, of a clear whitish or pale yellowish colour, a hot, pungent, bitterish, disagreeable taste, and a strong smell, without the aromatic flavour of the Chian kind. The true Venice turpentine is said to be obtained from the larch-tree, or pinus larix of Linnaeus (see Pinus), growing in great abundance on the Alps and Pyrenees, and not uncommon in the English gardens. For this purpose, incisions are made at about two or three feet from the ground into the trunk of the trees, and into these they fix narrow troughs, about twenty inches long. The end of these troughs is hollowed, like a ladle; and in the middle is a small hole bored, through which the turpentine runs into a receiver placed below it. The people who gather it visit the trees morning and evening, from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, it is clear, like water, and of a yellowish-white, but as it grows older, it thickens, and becomes of a citron colour. No trees under twelve inches in diameter are tapped; but vigorous trees will yield annually seven or eight pounds for forty or fifty successive years, or during the term of their life. Though this kind of turpentine bears the name of Venice, it is not the produce of the Venetian territories; it is brought from some parts of Germany, and one greatly resembling it, as it is said, from New England. It is also procured, in great abundance in the neighbourhood of Lyons, and in the valley of St. Martin, near Lucern, in Switzerland.

The turpentine flowing naturally, and called by the peasants bijon, is a kind of balm, not inferior in virtue to that of Peru. That drawn by incision, after the tree has ceased to yield spontaneously, is also of considerable use in several arts, and it is even of this that varnish is chiefly made. It must be chosen white and transparent; and care should be taken it has not been counterfeited with some other turpentine.

In the shops, turpentine of Venice is often supplied by a composition of rosin, and the distilled oil of common turpentine.

Turpentine of Strafburg is generally of a middle confidence between the two former, more transparent and less tenacious than either, in colour yellowish-brown, in smell more agreeable than any of the other turpentines, except the Chian; in taste the mottler, yet least acrid. This juice is extracted, in different parts of Germany, from the silver and red firs, (see Pinus Picea), by cutting out successively narrow slips of the bark, from the height which a man can reach, to within two feet of the ground. In some places, a resinous juice is collected from certain knots, under the bark; this, called lactyma abiegn, and oleum abietinum, is accounted superior to the turpentine. Neither this turpentine, nor any thing under its name, is at present common in the shops.

Common turpentine is about the confidence of honey, of an opaque, brownish, white colour, the coarser, heaviest, and in smell and taste the most disagreeable, of all the kinds of turpentine. It is obtained from the wild pine, (see Pinus Sylvestris,) which is extremely resinous; infomuch that, if not evaporated of its juice, it often swells and bursts. The tree is at its perfection when between seventy and eighty years old; but is fit to yield turpentine at the age of forty. Thoé trees which are most exposed to the sun, and have the thickest bark, afford it in the greatest abundance. Of the operations for procuring it commence in the month of May; the oil is first stripped off for six inches, so as to expose the inner smooth bark, near the foot of the tree, and a wound made with a sharp tool three inches square, and an inch deep. The resinous juice flows begins to exude in transparent drops, which fall into a hole previously dug at the foot of the tree; fresh incisions are successively made till September, when the cold begins to check the further evaporation. The warmer the weather is, the greater quantity of turpentine is obtained; and a healthy tree may thus yield from six to twelve pounds of turpentine annually, for a century of years. Part of the juice concretes in the wounds, and is called galiop in Provence, and barea in Guienne; but although it contains oil, yet it is not used for the purpose of procuring it. The proper turpentine is purified by being exposed to the sun's rays in barrels perforated in the bottom, through which it filters when liquefied by the heat.

The juice, as it issues from the tree, is sometimes received in trenches made in the earth, and afterwards freed of its greater impurities by colature through wicker baskets. The oil of the tree appears to contain a resinous matter, of a more grateful kind than that of the trunk; distilled while fresh, the are said to yield a fine effental oil, called by the Germain carpathicum oleum, much superior to that of the turpentines.

The oil of turpentine is obtained by distilling the resin with water in a common still, when the oil is found in the receiver swimming on the water, from which it is easily separated: the average proportion is 60 lbs. of oil from 250 lbs. of good turpentine. This process is carried on both abroad and at home; but the oil drawn in this country is always preferred.

The Canada turpentine (see BALSAM) is obtained from a tree which is a native of North America, that flowers in May, and is brought to this country in casks, each of which contains about one hundred weight. It has a strong not disagreeable odour, and a bitterish taste; it is transparent, whitish, and has the confidence of Copaiva balm.

Although Linnaeus, and several other writers on the Materia Medica, refer the common turpentine to the pineus sylvestris, and the terebinthina argentoratensis, or Strafburg turpentine, to the siber fir-tree; yet upon the authority of Murray, who follows Du Hamel and Haller, Woodville has ascribed the terebinthina vulgaris to the pinus picea, which pours out the turpentine so freely, that it is seldom necessary to make incisions through the bark for the purpose.

All these juices diffusse totally in rectified spirit, but give out little to watery menstrua: they become miscible with water.
water into a milky liquor, by the mediation of the yolk or white of an egg, and more effectually by mucilages. Distilled with water, they yield a considerable quantity of a subtilike, penetrating, effiential oil, vulgarly called spirit. Neumann says, that fifteen ounces of Venice turpentine, being distilled with water, yielded four ounces and three drachms of effiential oil; and the same quantity, distilled without water, yielded with the heat of a water-bath, two ounces only. The effiential oil cannot without great difficulty be distilled in spirit of wine; one part of the oil may be distilled in seven parts of rectified spirit of wine; but on standing a while, the greatest part of the oil separates, and falls to the bottom. After distillation of turpentine with water, a yellow or blackish resin remains in the still, which is the common rosin of the shops. See Rosin and Burgundy Pitch.

The effiential oil, re-distilled by itself in a retort, with a very gentle heat, becomes more subtilike, and in this state is called etherial; a thick matter remaining behind, called balsam of turpentine. A like balsam is also obtained by distilling with a stronger fire, the common rosin; from which there results, first, a thin yellow oil, and afterwards the thicker dark-reddish balsam, a blackish resin, called colophony, remaining in the retort.

All the turpentines are hot stimulants and corrupbants and detergents. They are given, where inflammatory symptoms do not forbid the ufe of them, from half a scruple to half a drachm and upwards, for cleansing the urinary passages, and internal ulcerations in general, and in laxities of the female and uterine vessels. They seem to act in a peculiar manner on the urinary organs, impregnating the water with a violet smell, even when applied externally, particularly the Venice fort. This laft is accounted the most powerful as a diuretic and deterrent, and the Chio and Strauburg as corrupbants. They all loofen the belly, but the Venice mol; and on this account they are suppofted by Riverius and others to be lefs hurtful than fuch irritating diuretics, as are not accompanied with that advantage. Dr. Cullen remarks, that terebinthine glifiers, in offinute colinvenes, are much preferable to falfes, as being more certain and durable. When turpentine is carried into the blood-vefSels, it ftimulates the whole ftystem; and hence its ufe in chronic rheumatifms and paralysis.

Turpentine readily paffes off by urine, which it imbues with a peculiar odour; also by perpiration, and probably by exhalation from the lungs: and to these repective effects are to be ascribed the virtues it may pooffes in gravelly complaints, fcoury, and pulmonic disorders. In all these diseases, however, and especially the laft, this medicine, as well as some of the gums and balfams of the terebinthinace kind, by acting as ftimulants, are often productive of mischief, as was first obferved by Boerhaave, and fince by Forthcgill.

Turpentine has been much ufed in geats and fluor albus; its efficacy in the former of thefe disorders is ascribed by Dr. Cullen, to its inducing fome degree of inflammation of the urethra: in proof of which he fays; "I have had fome inftances, both of turpentine and balfam of copaiva producing a manifeft inflammation in the urethra, to the degree of oc-

cationof a suppression of urine; but when these effects went off, the great which had fubfifted for fome time before, was entirely cured." Of thofe turpentines which we have defcribed, the Venice and Canada turpentines are more generally employed for internal purpofes, the Chian not being easily procured; and the common turpentine is offensive to most inftomachs, fo that its principal ufe is in fome external applications, among the farriers, and for the dilution of the oil.

The oil is a molt potent, ftimulating, deterrent diuretic. It is fometimes given, in dores of a few drops, in rheuma-
tilms and fixed pains of the joints; and fome have ventured on much larger quantities. Cheyne recommends (Eff. on the Gout, p. 199, ed. 10.), as a perfect cure for fepticisms, though of many years standing, from one to four drachms of the ethereal oil, to be taken with thrice its quantity of honey, in a morning fafting, with large draughts of fack-

The oil of turpentine, taken in too large a dofe, hath often very bad confefquences; fuch as a drangury, bloody urine, and its total fuppreffion, with a fever, violent third, and vomiting.

In the Medic. Eff. Edinb. vol. ii. art. 5. we have an account of fuch symptoms produced by the taking of two drachms of this oil in warm ale. The patient was cured by a warm bath, and drinking plentifully of Fuller's emuljo Arabica.

The oil has lately been given with beneficial effect in unusually large dores for the expulfion of the tape-worm. It differs in its action from the other remedies which have been employed inftant tape-worms, by killing the worm before itthrows it out, and hence it promises to be more permanently useful. The oil is ufeful when dropped into the ear in deafnefs occafioned by defect of wax. As a diftinent, it is applied to indolent tumours, and is an ufeful primary application to burn.

Turpentines are ufed in dores of grs. x to 3j; either made into pills with powdered liquorice-root, or dif-

subset in water by means of almonds, mucilage, or yolk of egg. The dose of the oil may be m x to 3j, to produce its diuretic effect; but for the expulfion of tapeworms, it is ne-

cessary to give from 3f to 5j, repeated every eight hours till the worm is thrown out. In these large dores, it is more easily taken when exhibited uncombined. The official preparations of turpentine are, the "oleum tere-
bintinum;" the "emphalium Galbani comp.;" the "un-

guentum elemi comp.;" and of the oil, "linimentum tere-
bintinum."

This oil is generally ufed as a drier, to mix with the other oils; for which purpose it has greatly the advantage of drying-oil, with regard to colour, as it is perfectly trans-

parent and white. It is ufed without any other preparation than mixing it, either alone or together, with drying-oil, with the other oils and colours. Turpentine is sometimes ufed with other bodies, to render spirit of wine a fit vehicle for colours.

The balfam and the infilipated refins are ufed chiefly exter-

nally: the balfam is lefs pungent than the oil, and the refins much lefs so than the turpentines in substance. The common yellow refin, in taffe considerably better, is some-

times given as an internal corrupbant, in preference to the turpentines themselves, as being dividted of the ftimulating oil. Turpentine, formerly much ufed as a digestive appli-

cation,
Turpentine may be of use to preserve the bodies of insects. Mr. Boyle took clear Venice turpentine, and evaporating to two-thirds, obtained a reddish transparent gum, clear of bubbles, easily soluble by heat, and as easily rendered brittle by cold. Having first pulverized it, he melted it for use, with a gentle heat, and dipped the body to be preserved several times in it, till it acquired a coat of due thicknesses.

**Turpentine, Balm, Oil, and Spirit of.** See Turpentine, supr.

**Turpentine-Tree.** See Pistacia.

This tree, besides its proper fruit, which succeeds the flowers in the usual way, is remarkable for producing what authors of little curiosity have named another fruit, called its horn. This horn is a membranous production, of the length and thickness of a man's finger; and what surprised those authors who esteemed it a sort of pod, was to find that it produced, not seeds, but living animals, which they called flies.

The true history of this horn is, that it grows from the surface of the leaves, not from the stalks, in the manner of fruit, and is no natural production of the tree, but a mere accidental thing, occasioned by the wound of an insect on the leaf.

A certain species of animals called pucerons, is peculiarly fond of the juices of the turpentine-tree, and always takes its abode upon its leaves; and these horns are produced in the same manner with the galls of other plants. See Puceron.

**TURPETH.** See Turrith.

**TURPIN, F. H., in Biography, an historical and biographical writer, was born at Caen in 1709, where he became a professor, but afterwards removed to Paris, and employed himself as a copious writer. As he avowed free principles of government, he was under a necessity of quitting France for some time; but he died at Paris in a state of indigence, betraying neither impatience nor regret, at the advanced age of 90 years. Nov. Dict. Hist.

**TURPINIA, in Botany, according to De Théis, is a new genus, dedicated by Humboldt and Bonpland, in their 5th fasciculus, to the honour of M. Turpin, an able botanical draughtsman, as well as a dotinglynaturalist, the author of several articles in the *Annales du Musée d'Histoire Naturelle.* Respecting the characters, clas, or order of this genus, we have no information; but the abilities of the person whose name it bears are conspicuous in the *Flora Parisiensis,* published by M. Poirot and himself, in folio, with splendid plates, printed in colours, a work which unfortunately remains imperfect, for want of encouragement.

**TURPINI, in Geography, a mountain of Silezia, in the principality of Tifehen; 4 miles E. of Jablukhan.

**TURPO, a town of Peru, in the diocese of Guamanga; 36 miles W.N.W. of Guanaca Velesa.

**TURQUOIS, See Turcois.

**TURREA, in Botany, received that name from Linnaeus; but whether he designed to commemorate George à Turre, superintendent of the botanic garden at Padua, in the latter part of the 17th century, or Anthony Turra, a botanist of his own time, remains uncertain. The former published at Padua, in 1685, a folio history of plants, without figures, entitled *Drydumam, Amadrydum, Cloridique Triumphus,* which Linnaeus, when he wrote his *Bibliotheca Botanica,* had never been able to meet with, and which, when he afterwards acquired it, certainly could contribute little to his information, being a mere compilation of obsolete opinions. Anthony Turra, who lived at Vicenza, printed in 1765, a 4to. dissertation on the *Farfettia,* a genus now established by Mr. Brown in *All. Hort. Kew.* v. 3. 96. He also published, in 1780, a *Flora Italica Pomediana,* and is the author of an Italian dissertation on the febrifuge virtues of Horle-chesnufi bark. We cannot but regret that so distinct a genus, remarkable for its elegance as well as rarity, should not be more decidedly or satisfactorily appropriated.—Linn. Mant. 2. 150. Sm. Plant. Ic. f. 1. 10. Schreb. Gen. 285. Wild. Sp. Pl. v. 2. 555. Mart. Mill. Dict. v. 4. Cavan. Diff. 7. 360. Juff. 264. Lamarck Illust. t. 351.—Cliffs and order, *Decandria Monogyna.* Nat. Ord. Tribulata, fett. 1. Linn. Mites, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, five-toothed, small, permanent. Cor. Petals five, linear, moderately spreading, very long, slightly dilated upward. Nectary a cylindrical tube, as long as the petals, or longer; its margin in ten acute spreading segments, sometimes divided. Stam. Filaments ten, very short, inserted between the teeth of the nectary; anthers erect, nearly ovate, emarginate. Pifl. German superior, roundish, style thread-shaped, about the length of the nectary; stigma rather obtuse, corrugated. Peric. Capsule roundish, depressed, five-lobed, five-celled, with ten valves, burbling lengthwise. Seeds kidney-shaped, two in each cell.

Eff. Ch. Calyx with five teeth. Petals five. Nectary cylindrical, bearing the anthers between its segments. Capsule superior, five-lobed, five-celled. Seeds in pairs. Linnaeus knew but one species of *Turrea,* sent him by Koenig. The writer of the present article has delineated that, with two new species, in his *Plantarum Icones,* and has now an opportunity of adding a fourth, making, with one described by Cavanilles, and another by Hallenius, six species in all. The whole are of a shrubby habit, with alternate, flaked, entire, simple, mostly undivided, leaves, without *fipalus,* and flaked, lateral flowers, remarkable for their great length.

1. T. virens, Evergreen Turrea. Linn. Mant. 237. Wild. n. 1. Sm. Plant. Ic. f. 1. t. 10. Cavan. Diff. 361 n. 524.—Leaves elliptic-lanceolate, emarginate, very smooth. Calyx and fruit silky.—Gathered by Koenig among the lava of extinct volcanoes in the East Indies. This is an evergreen *tree,* or *shrub,* with scattered, divaricated, round, brown, leafy branches, slightly silky in their youngest state only. Leaves about three inches long, on short thick stalks, smooth and shining on both sides, terminating in a short, broad, notched point; furnished with a strong midrib, and innumerable finely reticulated veins; their under side much the paler. Flowers in little, short, axillary *tufis,* on angular partial *flalks,* and accompanied by a few small leaves, as well as many linear silky *bratellas.* Calyx very small, silky, with five angles, and five small teeth. Petals and nectary smooth, slender and delicate, above an inch long; we should suppute them to be white, or pale flesh-coloured; Linnaeus thought the former, at least, were yellow. *Capsulat* a quarter of an inch in diameter, clothed with silky prominent hairs.

2. T. pubescens. Downy-leaved Turrea. "Hellenius in Stockh. Trans. for 1788. p. 256. t. 1e. f. 3." Wild. n. 2.—Leaves ovate, undivided or emarginate; down beneath. Flowers aggregate. Calyx villous.—Native of the island of Huanan. The fruit of this species has not been observed. We have never seen a speciment, nor are we peculiar of that particular volume of the Stockholm Transactions, in which alone it is described and figured. Having formerly however examined that work, in order to contrive this with the other species, we have no doubt of its being well defined.

TURRELL, in Geography, a market-town in the district of the same name, and shire of Aberdeen, Scotland; is situated on the banks of the Deveron, 34 miles N. by W. distant from Aberdeen, and 155 N. by E. from Edinburgh. It is a free burgh of barony, by a charter of James IV. granted in 1514, whereby it was entitled to hold a weekly market and two annual fairs; the market is well supplied; and the number of fairs has been increased to seven. The principal manufactures are those of linen-yarn, thread, and brown linen; and here is a considerable bleach-field. The church was rebuilt in 1794. Here was formerly an hospital belonging to the knights Templars; and also one for the poor of Old Aberdeen, founded in 1272 by Cumyn, earl of Buchan, and richly endowed in the succeeding century by king Robert Bruce. The parish of Turrell extends round the town about 34 miles in every direction, except to the N.W. where it is bounded by the Deveron. Agricultural improvements have been lately introduced; and here are several considerable plantations. In the population return of the year 1811, the inhabitants of the parish are stated to be 2227; the number of houses 502.

TURRETS, Moveable, in the Roman Art of War, were of two sorts, the lef and the greater; the lefs fort were about 40 cubits high, with square turrets, 17 cubits broad; they had five or six s, and sometimes ten or more divisions, each of which was open on all sides. The greater turrets were 120 cubits high, and 23 cubits square, containing sometimes fifteen, sometimes twenty divisions. They were of great use in making approaches to the walls, the divisions being able to carry soldiers, with engines, ladders, calling-bridges, and other necessaries. The wheels on which they moved were contrived to be within the planks, to defend them from the enemy, and the men who were to drive them forwards laid behind, where they were most secure; the soldiers within were protected by raw hide thrown over the turrets, and guarding those parts that were most exposed. See Tower.

TURRETED ISLANDS, in Geography, a small island in the Merigui Archipelago. N. lat. 10° 24'.

TURRÉTINI, BENEDICT, in Biography, an eminent Protestant divine, was the descendant of an ancient family of Lucca, and born at Zurich in 1588, being the son of a refugee from his country on account of his attachment to the principles of the Reformation; and in 1612 became a pastor and professor of theology at Geneva. He was employed in several successful missions, by the conduct of which he gained distinguished reputation; and died in 1631, with the character of an eminent theologian, and a man of prudence and moderation. His works were, "A Defence of the Syllogism in the German Version of the Bible," written in French, and comprised 400 pages, published in 1612; with a sequel in 1626; a variety of theological disputations in Latin, on the Calvinistic system of divinity; and sermons in Italian and French. Moreri.
His son, Francis Turrutini, was born at Geneva in 1623, and received his education under several eminent German professors, alio at Leyden, and afterwards at Paris, where he attended the lectures of Galiani. Returning to Geneva, he was admitted to the exercise of his ministry. Having for some time officiated as pastor of the Calvinist church at Lyons, he became, on his return to Geneva in 1653, professor of theology, in which station he continued through life. He was employed in various departments of public business, and died in 1687. Among other theological writings, didactic and controversial, he published "Institutionum Theologiae Elenchicae Partes tres," 1679—1685, exhibiting a fair and candid view of the points that were controverted between the different communions. Morei.

A son of the preceding, John Alphonso Turrutini, and the most celebrated of the name, was born at Geneva in 1671, and having, in consequence of distinguished talents and application, the tuition of able masters, access to a well-stored library, and an ample patrimony, laid the foundation of learning at home, he commenced, in his 20th year, his travels, and at Leyden studied ecclesiastical history under Spanheim. During his residence here he published, in 1692, his "Pyrrhonismus Pontificius, five Theses Theologico-Historiae de Variationibus Pontificiorum, circa Ecclesiae Infallibilitatem," designed to counteract the influence of Buffet's book "Les Variations des Eglises Protetantes," by shewing that the Roman Catholic church had been equally fluctuating in its opinions. At this time he visited England, and being introduced to Burnet, Tillotson, and Wake, he laboured to correct the false notions that were entertained by some English divines concerning the Genevan church. Upon his visit to Paris, he is said to have afforded the doctors of the Sorbonne, in a public disputation, by the purity of his Latin, the depth of his reasoning, and his polite manner of arguing. When he returned to Geneva, he commenced the exercise of his ministry in 1694, and was much admired as a preacher. The magistrates established for him, in 1699, a professorship of ecclesiastical history, the duties of which he discharged without any salary. These lectures were introduced with an oration, "De Sacramentis Ante Christum et Præchristianis," and the substance of these lectures comprised a body of ecclesiastical history, divided into more than 300 dissertations. In 1701 he was chosen rector of the academy of Geneva; and in this station, which he occupied for ten years, he delivered ten annual discourses, displaying eloquence united with erudition and excellent moral sentiments. Upon being appointed to the office of professor of theology in 1705, he delivered an inaugural speech, "De Theologo Veritatis et Pacis Studio," in his course of divinity lectures, he discussed the most important topics of divinity, without the formality of fylem; such as natural religion, the excellence and evidences of the Christian revelation, the perfections of the Deity, the interpretation of Scripture, and similar subjects. It was very much the object of his will to unite all Protentists; and with this view he took part with the German ministers who, in 1706, obtained a dispensation from the necessity of signing the formulary, intitled "Confessum," introduced during the violent disputes that had occurred concerning Grace and Predestination. Some other public offices were devolved upon him, which engaged his attention, and occupied much of his time and labour. His affable exertions, together with the uneasiness that was occasioned by the perturbed state of Geneva, are thought to have shortened his life, which terminated in May 1737, at the age of nearly 66 years. His works in 3 vols. 4to. were published in 1737; and after his death appeared his Com-

All botanists, who have examined into the subject, have found great difficulty in distinguishing this genus from Arabis (see that article); the character of the four prominent scales, or nectariferous glands, in the latter, being very uncertain. The best attempt at discriminating these genera that has ever perhaps been made, is Mr. Brown's, in the Hortus Kewensis, which is founded on the seeds of Arabis being ranged in a single row in each cell, while those of Turrutini compose a double one; for this is, in fact, the only real difference in our learned friend's characters. By his rule, Turrutini bifida and alpina are removed to Arabis; while Brafjica arvenis and Sifymbrium Loewfi, with probably some others, become species of Turrutini. In the latter case, great violence is offered to natural affinity, but perhaps the character itself is not clear in S. Loewfi, and its merit is therefore not invalidated by this species, whose close relationship to S. irdo we have noticed in the proper place. (See SYMIRNIA.) We are almost perverted of the merit of the above definition, in sending away to Arabis all the species of Turrutini which have a single row of seeds, and some of which have always been ambiguous. They meet in their genus with their natural allies. Nevertheless, as we have not yet treated of these species, we shall retain them here, for the present at least, indicating under each Mr. Brown's alterations, for the guidance of those who may wish to judge of his sentiments, and hereafter to conform to them. On subjects connected herewith, the reader will find some remarks under TETRADYNAIMIA.

1. T. glabra. Common Smooth Tower-multer. Linn. Sp. Pl. 930. Willd. n. 1. Ait. n. 2. Fl. Brit. n. 1. Eng. Bot. t. 777. Curt. Lond. fæc. 4. t. 47. Fl. Dan. t. 809. (Turrutini; Ger. Em. 272. Turrutina vulgaris; Clus. Fl. H. v. 2. 126.) — Radical leaves toothed, hairy; the root entire, clasping the stem, very small. Native of dry open gravelly places, in most parts of Europe, from Sweden to Greece, flowering early in summer. In England it is not one of the most common plants, being confined to a gravelly, chalky, or limestone soil. The root is annual, or biennial, tap-shaped. Stem simple, erect, wand-like, two or three feet high, round, smooth; covered with numerous, somewhat crowded or imbricated, erect, very smooth, ovate, acute, glaucous leaves, arrow-shaped at their base; while the
the numerous spreading radial leaves are very rough with partly forked hairs, toothed, or pinnatifid. Flowers cream-coloured, corymbose, very numerous, their common flaky greatly elongated, after flowering, into a dense cluster of long, slender, smooth, erect, flaked pods, each two inches long, and full of numerous small seeds, imbricated in two rows, as we have already mentioned, and not alternately crossing each other, so as to form a simple row. These seeds were formerly an article of the Materia Medica, being esteemed hot and dry, stimulating to the generative faculty, preferring against apoplexy, &c. virtues scarcely intelligible, or confusant.

3. T. trifida. Slender Tower-mustard. Allioni. Auct. 18. Willd. n. 3. — Leaves all smooth and shining: radical ones ovate, somewhat flaked, slightly toothed; the rett lanceolate, strongly toothed, fessile. — In meadows, and rather moist pastures, in several parts of Piedmont. Root white, woody. Stem two feet high, erect, quite simple, round, smooth, firm, clothed from top to bottom with alternate, close-pressed leaves, which are tapering, not arrow-shaped, at the base. Flowers small, white. Pods linear, flat, acute, erect, above an inch long, thin at the margin; the lower ones on longish flanks, and leaf crowded. This species is akin to T. hirsuta. Allioni.

4. T. hirsuta. Hairy Tower-mustard. Linn. Sp. Pl. 930. Willd. n. 4. Fl. Brit. n. 2. Engl. Bot. t. 587. Jacq. k. Rar. t. 126. Fl. Dan. t. 1048. Ehrh. Herb. 159. (T. n. 456; Hall. Hift. v. 1. 168. Arabis hirsuta; Scop. Carn. v. 2. 360. Brown in Ait. n. 91. Enyfimo simila hirsuta alba; Bauh. Prodr. 42. Barbarea muralis; Bauh. Hift. v. 2. 869.) — Leaves all rough, toothed in the middle. Stem hairy; the hairs simple and spreading. Branches straight, erect. Pod slightly quadranular. — Native of dry open pastures, and old walls, in most parts of Europe; not very common in England; flowering in May. The root is strong, woody, and, we believe, perennial. Stems generally several, one of which is much stronger than the rest, erect, a foot or eighteen inches high, leafy, branched, round, clothed with thick-facet, prominent, simple hairs, the flowering part only being smooth. Leaves toothed, chiefly about the middle, bluntish, all more or less hairy; the radical ones obovate, flaberd at the base, but not flaked; thoe on the stem fessile, or partly embracing it, rarely dotted at each side into a small auricle. Flowers numerous, small, white, not coloured. Pods forming a very long, close, erect cleft, all narrow, compressed, but the valves are more or less strongly keeled, so as to render the pod quadrangular; its surface is smooth and shining, beaded, in a manner, with the projecting seeds, which though inferted, of course, alternately, in two rows, range in one fimple series. When ripe the pods droop a little. Linnaeus originally confounded with this his T. alpina, whose leaves are all smooth on both surfaces; and also the following.

5. T. pascu. Early Tower-mustard. (T. n. 2; Ge-
The term *Turlut* (see Fl. Suec. 236.), but afterwards corrected that error. The *ros* is apparently bimodal. *Stern one*, or more, from two to twelve inches high, simple, erect, leafy, round, molyly smooth. *Leaves* all smooth on both sides, fringed with simple or forked, scattered, spreading hairs, a few of which are often clustered into a little tuft at the tips; the radical ones are greatly tinged with red. The more evidently the leaves are toothed, the less they seem to be fringed, as observed in Engl. Bot. Flowers white, larger than in *T. bifida*, forming a simple corymb, soon becoming a long cluster of narrow smooth *petals*, whose valves are very perceptibly keeled. Reyer's original specimen from Favrod proves his plant, and confluently that of Schleicher and Wildenow, to be the *Linnacean T. alpina*.

The *T. carules* of Allioni, Fl. Pedem. v. 1. 270. t. 40. f. 2, being considered as an *Arabis* by Wulfen, who is followed by Wildenow, *Sp. Pl. v. 3. 537*, as well as by Mr. Brown in Alt. Hort. Kew. v. 4, 1844, we shall leave it there. However naturally allied this plant may seem to be to our last-described *Tursis*, it is at least as much akin to *A. alpina*, bellidifolium, and others of that genus.

**TURRORAH**, in *Geography*, a town of Hindoostan, in Gooodwana; 20 miles S.W. of Coomath.

**TURROW**, a town of Hindoostan, in Bahar; 26 miles S.W. of Arrah.

**TURRUNG**, a river of Aizia, which empties itself into a lake, 18 miles S. of Candahar.

**TURSHISH**, sometimes written *Terchis* and *Terzib*, a town and district of Persia, in the province of Kho-rran, 63 furfungs W.N.W. of Herat, lately taken possession of by the troops of his Peruvian majesty. The old city, called Saltanabad, is small; but to this a new one has been added, where the governor and his principal officers reside. They both together contain about 20,000 people, amongst which are 100 Hindoo families. The trade of this place arises principally from the importation of indigo, and other drugs, from the westward; wool and cloth, and rice, from Herat; and the chief export is iron, wrought in thick plates. The trifling quantity of European goods required is brought from Mazanderan. Between this city and Herat the country is in general mountainous, wild, and uncultivated. Kinnir's Mem. of the Persian Empire.

**TURSI**, a town of Naples, in the Basilicata, the fee of a bishop, suffragan of Matera; 24 miles S. of Matera. N. lat. 40° 17'. E. long. 16° 30'.

**TURSIO**, in *Ichthyology*, a name by which Bellouius, Scaliger, and several others, have called the *phocaen*, or porpoise, difinificantly from the dolphin, with which it is confounded by the vulgar. See PORPESSE.

**TURSOSKA**, in *Geography*, a town of Hungary; 16 miles N. of Bolesko.

**TURTALA**, a town of Sweden, in Weft Bothnia; 45 miles N. of Tornea.

**TURTEREBES**, a town of Hungary; 14 miles N.N.E. of Zatmar.

**TURTLE**, in *Ornithology*. See COLUMBA.

**Turtle**, in *Ichthyology*, the name by which we commonly call the great sea-tortoise. See TORTOISE.

**Turtle-Shell, See TORTOISE and TORTOISE-Shell.**

**Turtle Bay**, in *Geography*, a bay on the west coast of Africa. S. lat. 14° 56'.—Allo, a bay on the south coast of New Ireland, so called by captain Carter. Dampier before called it "St. George's Bay"; and from Bougainville it obtained the name of "Prafin Bay."

**Turtle Creek**, a branch of the Monongahela river. At the head of this creek general Braddock was killed in 1755—Allo, a township of Ohio, in the county of Warren, containing 3442 inhabitants.

**Turtle Inlet**, a channel between two small islands, on the coast of New Jersey. N. lat. 35° 2'. W. long. 74° 47'.

**Turtle Island**, a small island in the East Indian sea. S. lat. 6° 35'. E. long. 132° 51'.—Allo, a small island in the South Pacific ocean, surrounded by a reef of coral rocks. S. lat. 19° 50'. W. long. 177° 57'.

**Turtle Lake**, a small lake of Canada. N. lat. 48° 54'. W. long. 71° 31'.

**Turtle Point**, a cape on the south coast of Java. S. lat. 7° 42'. E. long. 109° 58'.—Allo, a cape on the coast of West Florida, in the gulf of Mexico. N. lat. 29° 54'. W. long. 89° 4'.

**Turtle River**, a river of the state of Georgia, which runs into the sea. N. lat. 31° 12'. W. long. 81° 40'.

**TURTON**, a township of England, in Lancashire, with 1782 inhabitants; more than half employed in trade and manufactures; 6 miles S. of Blackburn.

**TURTOCAIA**, a town of European Turkey, in Bulgaria, on the Danube. In 1773, it was taken and burned by the Russians; 34 miles S.W. of Drifta.

**TURTUR**, in *Ornithology*. See COLUMBA.

**Turtur**, in *Ichthyology*, a name given by Paulus Jovius, and some other writers, to the fish called the *pallinaca marina*.

**Turtur, the Turtle-shell, in Natural History,* the name given by the collectors of shells to a very beautiful species of murex, common in the cabinets, but not found anywhere on the shores. This is owing to its having greatly altered its appearance in polishing; for it is not other than the white and brown-mouthed murex, which is common in its rough state, with its outer coat taken off.

**TURUTRA**, in *Geography*, a town of Naples, in Basilicata; 40 miles S. of Potenza.

**TURUTRANO**, a town of Naples, in the province of Otranto; 5 miles S. of Brindisi.

**TURUCHAN**, a river of Ruffia, which rises from a lake, N. lat. 67° 42'. E. long. 84° 14', and runs into the Enfei, a little south of Turuchank.

**TURUCHEA**, a town of Ruffia, in the government of Tobolsk, on the Enfei, formerly called "Mangafea." According to an old tradition delivered down from father to son, a colony from Archangel built the old oelrog of Mangafea, before any other Russian town existed in Siberia. It derives its name from a Samoidean tribe, who inhabited this country, calling themselves Mangale; who, by promising to pay tribute to the Russians, occasioned the building of the town. Old Mangafea, which stood on the river Taz, gradually fell to decay; in 1600, the present town was built, and the inhabitants of the old oelrog were removed hither. This new oelrog was also called "Mangafea," but as it lies at the mouth of the river Turukan, it had also the name of Turukanik, which it retains to this day. This oelrog proved the means of several nations becoming tributary to the Ruffians, it was probably on that account afterwards endowed with the privileges of a town. The houses in this town are not contiguous, and at most do not exceed one hundred. The greatest part of it is included within a small wooden fortification, with four pieces of cannon; and in this stands the house of the governor or prefect, and the principal church; and without it are two other churches. Most of the inhabitants have always been Cuffacks; who were placed here, in order to furbud, or at least to check, the Pagans nations, of this country, particularly the Tungufians and Samoidees; 724 miles N.E. of Tobolsk. N. lat. 65° 40'. E. long. 88° 44'.

**TURUNDA**, a tent, so called in *Surgery*, is usually composed of a bit of lint rolled up, or else of a piece of common sponge, or prepared sponge. Its general use is to keep

---
an opening from healing up too soon, in cafes of eblectes, disfigured bone, &c. Sometimes, also, it is used for dilating the aperture, by which means extraneous substances can be removed, without employing the knife. Tents have even been used for dilating the meatus urinarius, and thus enabling the surgeon to extract stones of considerable size from the bladders of female subjects.

TURUNGA, in Geography, a town of Hindooftan, in the circar of Ruttunpour; 24 miles N. of Raypore.

TURZA, or TURCETA, in Ancient Geography, Eylasht, a town of Africa, 6 leagues S.W. of Tunis, now a heap of ruins.

TURZEC, in Geography, a town of Lithuania, in the palatinate of Novgorod; 24 miles E. of Novgorod.

TURZO, TURZKA, in Ancient Geography, a town of Africa, mentioned by Ptolemy, situated eight leagues W. of Vicus Augufli.

TURZONZA, in Geography, a town of Mexico, in the province of Mechoacan, on the side of a lake; 25 miles W. of Mechoacan.

TUS. See Meschla.

TUSA, a fortrefs on the north coast of Sicily; 8 miles S.E. of Cefalu.

TUSANTLU, a town of Mexico, in the province of Mechoacan.

TUSBY, a town of Sweden, in Nyland; 15 miles N. of Helsingfors.

TUSCA, the Zaine, in Ancient Geography, a river of Africa, which seperated Africa Propria from Numidia.

TUSCAN, in Architecture, the first, simplest, and most massive of the five orders.

The Tuscan order takes its name from the ancient people of Lydia, who, coming out of Asia to people Tuscany, first executed it in some temples, which they built in their new plantations.

Vitruvius calls the Tuscan the ruffic order; with whom agrees M. de Cambrai, who, in his Parallel, says, it ought never to be used but in country-houses and palaces. M. le Clerc adds, that in the manner Vitruvius, Palladio, and some others, have ordered it, it does not defer to be used at all. But in Vignola's manner of composition, he allows it a beauty, even in its simplicity; and such as makes it proper not only for private houses, but even for public buildings, as in the piazzas of squares and markets, in the magazines and granaries of cities, and even in the offices and lower apartments of palaces.

The Tuscan has its character and proportions, as well as the other orders; but we have no ancient monuments to give us any regular Tuscan pillar for a standard.

M. Perrault observes, that the characters of the Tuscan are nearly the fame with those of the Doric; and adds, that the Tuscan is, in effect, no other than the Doric, made somewhat stronger, by shortening the shaft of the column; and simpler, by the small number, and largeness of the mouldings.

Vitruvius makes the whole height of the order 14 modules, in which he is followed by Vignola, M. le Clerc, &c. Serlio only makes it 12. Palladio gives us one Tuscan profile, much the fame as that of Vitruvius; and another too rich; on which fide Scamozzi is likewise faulty. Hence it is, that that of Vignola, who has made the order very regular, is most followed by the modern architects. See Column.

Of all the orders, the Tuscan is the most cafily executed, as having neither triglyphs nor dentils, nor modillions to vol. XXXVI.

scrap its intercolumns. On this account, the columns in this order may be ranged in any of the five frances of Vitruvius, viz. the pyramidal, stylofie, cufdfio, dianiole, or arvoffie. For the parts and members of the Tuscan order, their proportions, &c. see Capital, Base, Pedesimal, Freeze, &c.

TUSCANY, in Geography, now called Etruria (which, fee), a grand duchy or kingdom, long celebrated for the arts; the capital of which is Florence, which fee. Pinkerton states its length at about 120 British miles, and its breadth at 90; and its area of 7040 square miles as containing about 1,250,000 persons. The revenue is computed at about half a million Sterling; but the forces do not exceed 6,000 or 8,000. Tuscany is one of the most beautiful and fertile regions of Italy, with a temperate and healthy climate. It abounds in corn and cattle, and produces excellent wines and fruits. The mountains in the Sienese, or southern part of Tuscany, contain valuable ores of antimony, copper which is wrought at Maffa, and other metals, with flate and yellow marble. The serpentine of Impruneta, 7 miles S. from Florence, presents beautiful varieties used in ornamental architecture. Borax has been found in the lakes of Tuscany, near Sienna and Volterra. The Florentine marble is remarkable for picturesque representations of ruins, &c. caused by the infiltration of iron between the laminae. The river Arno receives many small streams; and the Ombrone is a considerable river which pervades the Sienese.

TUSCARAWA, a county of the district of Ohio, containing 3024 inhabitants.—Also, a township of Stark county, in the district of Ohio, containing 145 inhabitants.

TUSCARORA, a village of New York, inhabited by a tribe of Indians of the Tuscarora nation, consisting of about 300 souls, in the county of Niagara, about 23 miles E. of Lewiston. They have a good meeting-house and a Presbyterian clergyman; and also an English school. These Indians are sober and orderly in their general deportment, and many of them are respectable in point of wealth, as well as moral conduct. This tribe came from the S. about the year 1712, and joined the Five Nations or Iroquois. The land on which they now live was given them many years ago by the Senecas.

TUSCARORA, a town of North Carolina; 20 miles S.E. of Halifax.

TUSCARORA Creek, a river of Pennsylvania, which runs into the Juniata, 12 miles S.E. of Lewiston.

TUSCHAMA, a town of Russia, in the government of Irkutsk; 28 miles N.N.W. of Irkutsk.

TUSCHAMSKA, a town of Russia, in the government of Irkutsk; 100 miles N.W. of Irkutsk.

TUSCHGER See, a lake of Carnunia; 11 miles N. of Millhatt.

TUSCHNITZ, a town of Bavaria, in the bishopric of Bamberg; 10 miles N.E. of Lichtenfelds.

TUSCI, in Ancient Geography, a people of Attic Sarmatia, between mount Caucasus and the Caucaunian mountains, according to Ptolemy.

TUSCOMARTEE, in Geography, a town of Curlisfan, pleasantly situated to the north of the Tigris, at the foot of some hills, and well watered by several clear streams that flow from them. It commands a very fine prospect over an extensive vale to the south. In the summer season the sun is so powerful as to destroy all vegetation, except near the rivulets that flow from the mountains, where are found numerous flocks of sheep and herds of cattle. These, however, the shepherds are always obliged to drive to the town.
TUS

in the evening, on account of the wild beasts. In this vale no abode or habitation is visible for near 15 or 20 miles. Jackson's Journey from India, p. 120.

TUSCULAN, in Matters of Literature, is a term which frequently occurs in the phrase Tufcjan Questions. Cicero's "Tufcjan Questions" are disputations on several topics in moral philosophy, which that great author took occasion to denominate, from Tufcjanum, the name of a country seat, or villa, where they were composed, and where he lays the scene of the dispute.

They are comprised in five books; the first on the contemplation of death; the second on enduring pain; the third on alleviating grief; the fourth on the other perturbations of the mind; and the last, toshaw, that virtue is sufficient to a happy life.

TUSCULUM, in Ancient Geography, a town of Latium, at a small distance from Rome, towards the S.E. Its origin was referred to the time of Ulysses, whose son Telemon, by Cteis, is said to have been its founder. Its inhabitants were distinguished for their courage, and placed themselves at the head of the allies in the war of the Latin people. It was afterwards subdued by Rome and became municipal. Its situation on a mountain and between the hills induced the rich inhabitants of Rome to select it as the seat of their country-houses. It had a citadel of no less importance with regard to this city than the Capitol with regard to Rome. It had also an amphitheatre and aqueducts. It was afterwards denominated Frejus or Frejus, which see.

TUSCUM, or Thuscum Mare, the name of a part of the Mediterranean sea, which washed the coasts of Etruria, as far as the coasts of Sicily.

TUSGEL, in Geography, a town of Asiatic Turkey, in Caramania; 42 miles N.W. of Cogni.

TUSHES, in the Mange, are the fore-teeth of a horse, fitted beyond the corner teeth, upon the bars, where they shoot forth on each side of the jaws, two above, and two below, about the age of three, three and a half, and sometimes four; and no milk or foal-teeth ever come up in the place where they grow. See Teeth.

TUSHERI, in Geography, a town of Asia, in Daghestan; 80 miles S. of Tefhis.

TUSIAGATH, in Ancient Geography, a town of Africa, in the interior of Mauritania Cæsariensis, according to Ptolemy.

TUSIS, in Geography, a town of the Heleotian republic, in the Grisons, on the Rhine. In 1799, it was taken by the French; 15 miles S. of Coire. N. lat. 46° 32'. E. long. 9° 30'.

TUSK, in Carpentory, a bevel-shoulder, made to strengthen the iron of the joint, which is let into the gider.

TUSK, in Zoology, is used to denote the long tooth of a fighting animal; and in the fennite with tuftes, as applied to other animals besides horses.

TUSKAR, in Geography, a small island, or rather rock, off the coast of the county of Wexford, Ireland, forming a conspicuous object for mariners. N. lat. 52° 15'. W. long. 6° 10'.

TUSKAU, a town of Bohemia, in the circle of Platen; 6 miles N.W. of Teinitz.

TUSKAWARA, a township of Muskoggin county, in the district of Ohio, containing 1151 inhabitants.

TUSO, in Ancient Geography, a river of India, on this side of the Ganges, into which it runs.

TUSPA, in Geography, a town of Mexico, in the province of Mechoacan; 25 miles N.N.E. of Colima.—Alfo, a town of Mexico, in the province of Tlaxcala, at the mouth of a river so called; 140 miles N.N.E. of Puebla de los Angeles.—Alfo, a river of Mexico, which runs into the gulf of Mexico, N. lat. 21° 28'. W. long. 98'.

TUSSEY, in Geography, the name of mountains of Pennsylvania; 10 miles N. of Huntingdon.

Gen. Ch. Common Calyx cylindrical, tumid at the bottom, of from fifteen to twenty linear-lanceolate, equal, somewhat membranous scales, the length of the disk. Cor. compound, various. Florets in some all perfect, tubular, funnel-shaped, with an acute, four or five-cleft, reflexed limb, longer than the calyx; in others such florets are found in the disk only. Female florets when present either ligulate, very narrow, undivided, longer than the calyx; or tubular, and rather longer than the perfect florets. Stam. in the perfect florets, Filaments five, capillary, very short; anthers more or less united into a cylindrical tube. Pet. Germen in the perfect florets, short; style thread-shaped, longer than the filaments; stigma thickish, emarginate: in the female ones, Germen short; style thread-shaped, the length of the former; stigma deeply divided, acute. Perianth, except the scarcely altered calyx. Seeds solitary, oblong, compressed, generally abortive in the florets of the disk, or centre thereof. Down capillary, sometimes flaked. Recept. naked, dotted. Eft. Ch. Receptacle naked. Seed-down simple. Calyx simple.
TUSILAGO

simple, of many equal, somewhat membranous leaves; tu-
mid at the base.

Obs. Linnaeus remarks, that Petasites of Tournefort
has no ligulate florets in the radius, though some female
naked ones occur: Tufiflago of the fame author has always
two female florets in the radius, furnished with a ligulate corolla: 
Anandria of Linneus himself, Am. Acad. v. 1. 243, has
seflie feed-down; and T. frigida varies with or without a
radius. These confidences are indeed variable at all times, but
ef pecially in the genus now under confideration. We
have mentioned in Fl. Brit. that some reputed species appear
near to be but different flxes of one and the fame. Of this
the Britifh T. hybrida and Petasites are one infance. We
shall indicate other similar cafes, in which it feemes Ehrhart
has forestalled us, in his Beiträge, v. 3. His difcoveries are
confirmed by Hoppe; and both these authors are followed
by Willdenow, without any reference to the Flora Britannica,
unto which however the publication of Hoppe is three years
posterter. We are well affured that this apparent negletct
was not intentional, and the obervations in question, having
been made by each perfon independently, derive from thence
the more authority. The whole genus of Tufiflago is herba-
ceous, without any stem. Leaves falked, fimple, angular,
toothed, more or lefs heart-shaped. Pubfence of the herbage
cottony, dense, generally remarkable for its pure whitefens, and
foft texture. Flowers white, or pale red; sometimes yellow,
etrally solitary, or denfely panicked. Seed-down of a
brilliant livery white.—Willdenow reckons up twenty-one
species, but his firft two, T. Anandria and lyrata, will be
found under our article Perdicum, fp. 3. and 4; his T.
lyrata being Gmelin's t. 67. f. 2, mentioned under our Per-
dicum popiferifenum, n. 4, as a probable variety of Anandria.
Willdenow's 4th species, T. inteflifolos, is Chaptalia tomens-
tofa, Venten. Jard. de Cels 61. Pursh 577. If not a good
genus, it must be referred to Perdicum; being certainly no
Tufiflago. Very possibly the third species of Willdenow may
also belong to Perdicum; but this being a very uncertain
plant, known from Plumer's figure only, we muft leave it as
we find it, among other fpaces placed here by authors,
but which to us are by no means free from doubt as to their
generic characters; nor can that queftion be decided without
an investigation and comparifon of their fresh flowers.
Sp. Pl. 1213. Wildl. n. 3. (A. d. acutus, hieracioides volhos,
folius; Pl. ic. 28. t. 0. 211.)—Stalk fingle-flowered, 
naked. Flower radiated, creft. Leaves fefile, oblong,
waft, toothed, villos.—Gathered by Plumer in the Weft
Indies. The root appears to be fibrous. Leaves numerous,
three or four inches long, with an undulated ftrongly
toothed margin. Flower-flols also numerous, though fewer
than the leaves, smooth. Flowers radiated, somewhat like
our common T. Farfara, but much smaller.
2. T. albicans. Whitish Jamaica Cofts-foot. Swartz
Ind. Occ. 1348. Wildl. n. 5. (Leontodon tomentosum;
Linn. Suppl. 347.)—Stalk fingle-flowered, naked; cottony
at the top. Flower radiated, drooping. Leaves falked,
obovate, with flight reverfed ferratures; cottony benef;
tapering at the bafe.—Native of dry gravelly inland paitures,
in the western part of Jamaica. Swartz. Sent to Lin-
neus in Browne's herbarium. Root fibrous, probably pe-
enent, though marked annual. Leaves two or three inches
long, of a narrow obovate form; green and nearly naked
above; fnow-white beneath; their margin fliitely waft,
hefet with minute diftant teeth, all pointing backwards.
Stalks few, often a foot high, round, reddish, fliitute of
leaves or bracteas, clothed about the top, for near two inches,
with dense cottony down. Flower white, drooping as it
fades; according to Swartz's defcription it anfwers to the
characters of this genus. Seed-down shining, with a reddith,
or pink, hue.
Occ. 1350. Wildl. n. 6.—Stalk fingle-flowered, naked,
downy. Flower radiated, creft. Leaves obovate, with
reverfed teeth; finated at the bafe; downy beneath.—
Found on the lofty calcareous mountains of the fouth part
of Jamaica, near Cold-fpring, flowering in fummer. Smaller
than the lat, to which it feemes nearly allied; but the leaves,
only an inch or two in length, are pinnatifid in a lyrate man-
ner. Stalk ftrongly folitary, from three to fiix inches high,
roundifh, cottony; purplifh in the lower part. Flower
small, white; creft according to Willdenow, and the
fpecifc character of Swartz, though the latter calls it drop-
ing in his defcription. Its ftucture is that of a Tufiflago.
Swartz Obf. 305. (Leontodon n. 1; Browne Jam. 310.
Dens leonis, folio fubius incano, flore purpureo; Sloane
Jam. v. 1. 255. t. 150. f. 2. After primula veris folio,
flore fingulari purpureo; Plum. ic. 29. t. 41. f. 1.)—Stalk
fingle-flowered, naked, cottony. Flower radiated, penden-
ous. Leaves falked, oblong-heartfped, wavy, toothed;
cottony benef; finated at the bafe.—Native of culti-
vated and granfy places in Jamaica. Swartz defcribes it as
an annual. Mr. Atton marks it biennial, flowering in the flove
in June and July. The much larger leaves, near a fapan
long, pinnatifid in a lyrate manner, and the fflats twelve or
fifteen inches high, diftinguifh this species from all the pre-
ceding. The flower is pendulous, with a white difk and
radius, but the fendler points of the calyx-folias being fipped
with purple, have, as it appears to us, been miftaken for
a purpfe radius by Sloane, and even by the more learned pro-
feffor Swartz. When in feed, the ftalk becomes creft. The
down is rather tuawny, or reddith.
Pl. Magell. 28. Wildl. n. 8.—Stalk fingle-flowered, fealy.
Flower radiated, creft. Leaves fpatulate, with three or
more oblong fegments, smooth.—Native of dry hilly fitu-
aftions about the ifrata of Magellan. Root peennier, fome-
what tuberous. Leaves radical, tufted, an inch long, di-
vided into three, four, or five, oblong, creft, finger-like
fegments, spreading, quite smooth and naked. Stalk from
one to three inches high, round, clothed with awk-fpaped
fealy bracteas. Flower white, with all the characters of its
genus. Inner fcales of the calyx largeft, with spreading
horizontal points.
t. 84. (T. alpina fecunda; Clus. Hift. v. 2. 113. Aferanis;
Matth. Valgr. v. 1. 34. A. Matthioli; Ger. Em. 836.)—
Stalk fingle-flowered, with oblong scattered bractceas.
Flower without rays. Leaves kidney-shaped, toothed,
smooth on both fides.—Native of the alps of Auffria,
Bohema, Switzerland, &c. flowering in June and July. The
root is peenniel, tuberous, and creeping, brown, with many
long fibres. Leaves few, radical, falked, from one to two
inches broad, bluntly toothed; quite smooth, and of a fliit-
ing green, reticulated with defpried branching veins above;
paler beneath, but equally smooth, except feeve hairs on the
ribs or veins. Stalk folitary, a foot or more in height, creft,
purplish, hairy, bearing a few diftant, varioufly shaped, con-
cave, upright bracteas. Flower creft, half an inch broad.
Calyx purple, smooth. Florets white, sometimes purplifh,
all regular and fide-eft, with purple anters and fligans.

1. 247.
TUSILLAGO.

1. 247. Willd. n. 10. Ait. n. 3. (T. alpina; Linn. Sp. Fl. 1214.) T. alpina prima; Chuf. Hift. v. 2. 112. T. alpina; Ger. Em. 812.—Stalk single-flowered, nearly naked. Flower without rays. Leaves kidney-shaped, toothed, downy and white beneath.—Native of the Alps of Austria, Carniola, &c. growing along with the leaf, and flowering at the same season. This is rather smaller than the preceding, usually with fewer bracteas. The under side of the leaves is clothed with dense white cottony down, which affords the most distinguishing mark of this plant. It is preferred by pot authors to prove it specifically distinct. Linnaeus thought it but a variety.

8. T. falcifera. Lobed Alpine Colt’s-foot. Scop. Carn. v. 2. 157. Jacq. Auct. v. 5. Append. 33. t. 12. Willd. n. 11.—Stalk mostly single-flowered, with dilated scattered bracteas. Flower without rays. Leaves smooth, kidney-shaped, many-lobed and toothed.—Native of mountainous, chiefly beech, woods of Styria, Carnithia, &c. flowering in May. Allied to T. alpina, to which it has been confounded by Scopolii, Haller, and even Jacquin; but the leaf has the merit of sub-frequently distinguishing this very well-marked species. It is larger than alpina, and the flae sometimes bears two or three flowers, scarcely differing from those of alpina or discofus. The bracteas however are broader, often terminating in a leafy appendage, particularly the lower ones. The radical bracteas are very different, being cut into about seven rather shallow lobes, of which the middle ones more especially have about three pointed teeth. The upper surface is green, sometimes roughish to the touch, slightly marked with veins; the under paler, peculiarly smooth and even, a little shining. We have not heard of this plant in any British garden, nor had Linnaeus a specimen.

9. T. Forfora. Common Colt’s-foot. Linn. Sp. Fl. 1214. Willd. n. 12. Fl. Brit. n. 1. Engl. Bot. t. 429. Curt. Lond. fasc. 2. t. 60. Woody. Med. Bot. t. 13. Bulliard Herb. de la Fr. t. 329. Fl. Dan. t. 195. (Tussilago; Ger. Em. 811. Matth. Valgr. v. 2. 198. Camer. Epit. 590, 591.)—Stalk single-flowered, fealy. Flower radiated. Leaves heart-shaped, angular, toothed; downy beneath.—Native of moist chalky sandy situations, throughout Europe; flowering in March or April, before the leaves appear. Dr. Sibthorp met with it about hills and inundated places in Greece, nor can there be any doubt of our Colt’s-foot being the βαντα of Dioscorides, of which Farfora, fee that article, is an ancient synonym. The roots of this species are perennial, creeping to a great extent. Stalks five or six inch high, erect, lumpy, downy, clothed with numerous, alternate, ovate, erect, purplish, nearly smooth scales, three-quarters of an inch long. Flower drooping before it expands, then erect, yellow, an inch broad; the radius of very numerous, long, narrow, spreading, ligulate flae, which Dr. Stokes has observed to be the only ones that ever perfect their seed. Indeed the plant increases so much by root, that fearlessly any seeds are ever ripened. The leaes come forth on erect footstalks, after the flowers and their stalks have withered, and are from three to six inches wide, harshly toothed; very smooth, and rather glaucous, above; covered beneath with dense, white, cottony down. They are mucilaginous and aromatic, slightly bitter, and are recommended either in infusion, or smoked like tobacco, as a cure for coughs. The latter mode of application is advised by Dioscorides in difficulty of breathing, dry cough, &c. and he recommends these leaves bruised, with honey, as an external remedy for coughs, and other inflammations of the skin. The cottony web of this herb serves extremely well for tinder, and to staunch the blood of flight wounds.—Wildenow says there is a variety with perfectly smooth leaves.

10. T. japonica. Japan Colt’s-foot. Linn. Mant. 113. Willd. n. 13. Thum. Jap. 313. Banks 1c. Kämpf. t. 27, 28. (Arnica tussilaginis; Bum. Ind. 122. Doro-nicum tussilaginis folio, &c.; Pluk. Amahi 71. t. 390. f. 6. Twa; Kämpf. Am. Exot. 827.)—Stalk with several radiated flowers, corymbose, bracteate. Leaves roundish-heart-shaped, toothed; slightly downy beneath.—Native of Japan. Flowers in October; Raint teenager, tuberous. Stalks twelve or fifteen inches high, angular, furrowed, reddish, downy in the upper part, bearing a few scattered fealy bracteas, and terminating in from five to eight large yellow radiated flowers, on downy alternate partial stalks. Rays wedge-shaped. The seed-down is fealy, like the leaf. Leaves coming after the flowers, on long upright footstalks; their breadth three or four inches; length much less; their under side paler, but scarcely downy. The root, according to Thunberg, is bitter, and esteemed a counter-poison by the Japanese. Kempfer says the flae are used as a pot-herb.

11. T. frigida. Lapland Colt’s-foot. Linn. Sp. Fl. 1214. Fl. Lapp. ed. 2. 246. Willd. n. 14. Ait. n. 5. Purth n. 1. Fl. Dan. t. 61. (T. n. 128; Gmel. Sib. v. 2. 150. t. 70.)—Stalk with many radiated flowers, corymbose, bracteate. Leaves triangular-heart-shaped, with deep triangular teeth; downy beneath.—Found by Linnaeus plentifully in woods and pastures among the Lapland alps, flowering towards the end of May, and shedding its seeds about a month afterwards. It occurs likewise in Norway and Siberia, as well as, according to Mr. Purth, in Canada, and on the highest peaks of the Vermont and New Hampshire mountains, at the same season. The root is somewhat tuberous and creeping, though less flaky than the leaf, with copious long fibres. Leaves and flowers appearing nearly together, on footstalks about equal in height, from ten to fifteen inches; the former remarkable for their very large angular teeth. The flower-footstalk bears several alternate, large, thick, smooth bracteatas, sometimes coming in a small leaf. Flowers white; the flae of the disk tinged with pale purple, especially their large, club-shaped, hairy, prominent, but we believe unfeathered, sigmas. Seed-down fealy, above an inch long, fibrous.

12. T. fragrants. Sweet-scented Colt’s-foot. Villars Actes de la Soc. d’Hifi. Nat. de Paris, v. 1. t. 12. t. 12. Willd. n. 15. Ait. n. 6. Curt. Mag. t. 1388.—Stalk panicked, level-topped, somewhat leafy. Flowers radiated. Leaves roundish-heart-shaped, oblong, equally and finely toothed; rather hairy beneath.—Native of the neighbourhood of Naples, and of Sicily near Palermo; introduced into England by Meffrs. Lee and Kennedy in 1806. It flowers in the winter, or early spring. The leaves, which are green on both sides, rounded, obtuse, not at all lobed or cut, appear with the flowers. The latter are large, fragrant like Heliotropium peruvianum, with broad light-purple rays, and a white disk, the ausmas of whose flores is dark-purple. The panicle is compound, rather dense; its stalk taller than the foliage, clothed with very large inflated bracteas having leafy terminations.

13. T. levigata. Smooth Straw-coloured Colt’s-foot. Willd. n. 16. (T. forado imbriciato, floribus spicatis radiatis, foliis utrinque glaberrimis; Gmel. Sib. v. 2. 148. n. 126.)—Stalk panicked, level-topped. Flowers radiated. Leaves heart-shaped, acute, slightly angular, toothed, smooth on both sides.—Abundant about the mouths and shores of rivers in Siberia, flowering in spring, at which time all but the flowers is generally under water. Gmelin. Root flaky, purplish,
purpurine, creeping to the extent of many feet, with many long, thick, fimple fibres. *Leaves* about two inches broad at the flowering period, but when full grown, eighteen inches in diameter; bright green and smooth, or birst, purpurine at the edges, *f.lur*; copiously veined beneath; their margin irregually and sharply toothed, sometimes angular. *Flowers* smooth, a foot or more in length. *Flower stalk* taller than the leaves, thick, succulent, reddish, sriated, slightly cottony, bearing many large, inflated, feathering *bracteae*, and terminating in a more or less compound, level-topped, or corymbose, *panicle*, whose downy flakks are furnished with many smooth, linear-lanceolate, flt, much smaller *bracteas*. *Flowers* from eight to twenty, scarcely an inch in breadth, fbraw-coloured, with short frhys.

Willdenow's opinion of this being a very distinct species, is confirmed by Gmelin's *own spicimens* in the Linnæan herbarium; which also, unless we are greatly mif- taken, shew n. 127. t. 69, D, E, of the same author, to be the very fame plant, totally different from the common T. *Petajites*, with which he compares it; in many other points besides the colour of the *flowers*. 14. T. *alba*. White Colt's-foot, or Double-toothed Butter-burr. Linn. Sp. Pl. 1214. Willd. n. 17. Ait. n. 7. Fl. Dan. t. 524. (Petajites flore albo; Camer. Epit. 593. P. n. 1391; Hall. Hift. v. 1. 61.) —Panicle denfe, level-topped. *Flowers* without rays. Leaves roundish-heartshaped, doubly and sharply toothed; white and fhaggy beneath. —In mountainous woods, and about the banks of rivers, in the alpine parts of Europe, not rare in Switzerland, but unknown as a native of Britain. It appears to have been cultivated at Edinburgh in the time of Sutherland, 1683, and we obtained a specimen from the botanic garden there 100 years after, under the erroneous name of T. *hybrida*. This is a large species, distinguished from all the rest, of those which bear many flowers on a flak, by its strongly, doubly, and acutely-toothed *bracteae*; quite smooth above; very weiny and cottomy beneath, when young, but afterwards the pubefeence of that fide becomes more grey, fhaggy, and lofe. The tall downy *flower stalk* bears a great number of broad, concave, rather cottony *bracteas*, and terminates in a branched manyflowered corymbose *panicle*. The *flowers* are rather fmall, snow-white, without rays. Dofen felfife. Willdenow and other botanifts have obferved, that fome individual plants have but very few, and others many, female *flowers*, in comparison to thofe, furnished with both *flamen* and *pifils*; but the author juft named has mifled by Villars to cite, as the female plant of this species, Gmelin's t. 69. f. D, E, which has yellow *flowers*; see our n. 13.

15. T. *nivea*. Snowy Colt's-foot, or White-leaved Butter-burr. Villars Actes de la Soc. d'Hift. Nat. de Paris, v. 1. 73. t. 12. f. 2. Willd. n. 18. Ait. n. 8. (T. rigida, p. Villars Dauph. v. 3. 175, T. paradiza, Retz. Obi. f. 2. 24. t. 3. Petajites n. 141; Hall. Hift. v. 1. 62. P. minor, trifluage folio; Moril. feif. 7. t. 10. f. 4.) —Panicle denfe, rather oblong. *Flowers* without rays. Leaves triangular-heartshaped, simply toothed, with spreading angular lobes; densely downy and white beneath. —Native of the mountains of Switzerland, Germany, Dauphinie, &c. *Flowering in April*. Differs from the lat in the snowy whitenefs, and defe pubefeence, of the under fide of the *leaves*, as well as in their triangular form, and their fimple margin of marginal teeth. *Flowers* pale fclaw-coloured. Common *flak* clothed with ftlicht large *bracteas*. Seed-down near an inch long. The female plant, termed *paradiza*, as aiftinct species, by Retzius, has but about three appa rently perfect *flowers* in each *calyx*, and of t'hese the amber
destitute of a corolla, which is Elsholtz's townensis; the other with a more elongated corymb, and numerous female florets, each with an oblique tubular corolla, but whose disk may nevertheless be said to be small and barren; this is the original paradoxa. We presume the idea of the barren disk may be a mistake of Retzius; that part, when imperfect, being, in this tribe of plants, always thickened; but we have had no opportunity of examining living specimens of T. spuria, which is a stranger to the gardens of England.

19. T. palmata. Cut-leaved Colt's-foot. Ait. n. 10, ed. 1. v. 5. 188. t. 11. Willd. n. 21. — Flowers corymblose, level-topped, radiated. Leaves feven-lobed, palmate, cut; downy beneath.—Native of Newfoundland and Labrador. Introduced into England by Dr. Fothergill, in 1777. Perennial, flowering in April. The leaf and inflanceence resemble the lali. The flowers are light flesh-coloured, or purplish, with short obtuse rays. The leaves, which by Wildenow's account vary in the depth of their lobes, afford a clear specific difference from all the other species.

Tussilago, in Gardening, comprehends plants of the low, hardy, herbaceous, creeping-rooted perennial kinds; among which, the species most commonly cultivated in gardens for different purposes are, the common tussilago or colt's-foot (T. farfara); the mountain colt's-foot (T. alpina); the Siberian colt's-foot (T. anandra); the petasites, tussilago major, or common butter-bur (T. petasites); the hybrid German tussilago, greater colt's-foot, or long-flaked butter-bur (T. hybrida); and the white alpine tussilago, or smaller butter-bur (T. alba).

The first fort has a creeping perennial root, short, thickish stalk, with fine roundish hoary leaves; which are produced after the flern and flower; hence it is denominated one of the triste ante patrem, or son before the father, tribe or class of plants, or thoe in which the flowers rise before the leaves.

It is not much cultivated in the garden manner, except in herbaceous collections as a medicinal herb for making decoctions and other mild balsamic drinks, and for the use of its leaves as a principal ingredient in the preparation of the British herb tobacco, and other similar compositions. Sometimes, however, it is employed for variety in patches in the borders and other parts of ornamented grounds.

In the second kind, there is a variety which has round hoary leaves.

The fourth fort is also sometimes cultivated and employed as a medicinal plant in different intentions.

Method of Culture.—They are all capable of being raised and increased by sowir the seeds of them in any proper and suitable soil and situation in the early spring season; but not to too great a depth, when they will freely rise and become good plants. But the bell and most expeditious method is that of parting the roots and planting them, which may be done either in the autumnal or spring season, when the smallest flbr will readily take root and grow, multiplying in a very quick manner.

Most of the forts possess the singular property of producing and sending up their flowers and stalks before the leaves are formed and seen.

The plants mostly affect rather moist soils and situations, but they will grow and succeed almost any where, and may be employed for affording greater variety and ornament, as well as some of them for the purposes and intentions which have been suggested above.

Tussis. See Cough.

Tussilagin, in Geography, a town of Bavaria; 4 miles W.S.W. of New Otting.

Tut, in Armor, &c. an imperial ensign of a golden globe, with a crofs on it.

Tut Bargain, among the Miners, denotes a bargain by the lump; as when they undertake to perform a piece of work at a fixed price, however it may prove.

Tutacorin, or Tuttcorin, in Geography, a town of Hindooftan, in the Carnatic, where the Dutch have a factory; 25 miles E. of Palamotta.

Tutary, a town of Sweden, in the province of Smaland; 24 miles W. of Wexio.

Tutbury, or Stutbury, a market-town in the hundred of Offlow, and county of Stafford, England; is situated on the western bank of the river Dove, at the distance of 4 miles N.W. by N. from Burton-on-Trent, and 134 miles in the same bearing from London. It was erected a free borough at an early period, and the burgesses and other inhabitants were invested with a variety of priviliges and immunities; but never had the right of sending members to parliament, though the town still retains the appellation of a borough. The parish-church is an ancient and spacious edifice, with a square embattled tower, surrounded by four small pavements; its principal entrance is decorated with fine specimins of Saxo sculpture. A free school was founded and endowed by Richard Wakefield in the year 1730; it was rebuilt in 1789. Here is also a meeting-house for Dissenters. According to the population register of the return of the year 1811, the parish of Tutbury contained 242 houses, occupied by 1235 persons. Wool-combing constitutes the principal business of the inhabitants; and a cotton manufactury, recently established, gives employment to a considerable number. Three fairs are held annually, and a market weekly, on Tuesdays. On the north side of the town are the remains of the castle of Tutbury, which was erected soon after the Conquest, by Henry de Ferrars, a noble Norman, to whom the Conqueror gave large eftates in this county. In the family of Ferrars it continued till the reign of Henry III., when, being forfeited by the attainer of Robert de Ferrars, earl of Derby, the king granted it to his second son Edmund, earl of Lancaster. It again reverted to the crown, in consequence of the rebellion of Thomas, earl of Lancaster, who fortified it against Edward II., but was obliged to surrender. Having sustained considerable damage during this contest, and being afterwards suffered to fall into decay, John of Gaunt rebuilt the greater part of it upon the ancient site in 1350. This castle, being the principal seat of the dukes of Lancaster, was long distinguished as the scene of much fertility and splendour. So great was the number of minstrels resorting to it, that it was found necessary to adopt special regulations for the preservation of order. Accordingly, one of their body was invested with the title of king of the minstrels, with officers under him for the due execution of the laws. A charter for that purpose was granted by John of Gaunt in 1381; and a court was established for determining all controversy connected with minstrelsy. At this court, which was annually held with great formality, the king and his officers were appointed for the year ensuing; and the bunneys of the day concluded with a bull-running and baying. This barbarous custom was abolished, by commutation, about the middle of the last century; but the court still continues to be held. Tutbury cattle was twice the residence, or rather prison, of Mary queen
queen of Scots; in 1568, and again in 1589. At the commi-
ncement of the civil war in the reign of Charles I. it was
warranted by lord Loughborough, a zealous supporter of
the royal cause; but was besieged and taken by sir William
Bretton, one of the parliamentary commanders. The
damage sustained by the castle on this occasion was very
great; but it was not doomed to total destruction till
1646, when, by order of the parliament, it was reduced
nearly to its present ruinous condition. What still remains,
sufficently declares its former extent and grandeur; the
ancient gateway is tolerably entire; and towers, staircases,
divisions of rooms, and fire-places, can yet be discovered in
different parts of the walls, which appear to have been of
immense strength and thickness: the whole was surrounded
by a broad and deep ditch, over which, Dr. Plot informs
us, there was in his time an extraordinary timber-bridge,
composed of distinct pieces of wood, none of them above a
yard long, yet unsupported by any arch-work, pillars, or
other prop. Coeval with the castle, and founded by the
fame perfon, was a Benedictine priory, largely endowed by
king William Rufus. The site was granted by Edward VI.
to sir William Cavendish. Scarcely a vestige of the ancient
building is now left, and we know little more of its struc-
ture, than that it was of large extent, and contained a
splendid monument to the memory of the founder. A
portion of the old priory church constitutes a part of the
present parish-church.—Description of the Castle and
Priory of Tutbury, 8vo. 1796. Beauties of England and
Wales, vol. xii. Staffordshire, 1814.

TUTELA, in Ancient Geography, a town of Spain, in
Celtiberia, according to Martial.

TUTELA, in Mythology, a goddes worshipped at Bour-
deaux, of which city she was patroness, and where she
had a magnificent temple. She is suppos'd by learned antiquaries
to have been a divinity peculiar to sailors and merchants,
who trafficked upon the rivers, as it was a common praetice
to put upon their ships the figures of certain gods, who gave
names to them, and were called by the ancients "Tutela
Natis," the tutelar divinity of the ship.

TUTELARY, TUTELARIS, one who has taken some-
things into his patronage and protection.

It is an ancient opinion, that there are tutelary angels of
kingdoms and cities, and even of particular persons, called
guardian angels.

The ancient Romans, it is certain, had their tutelary gods,
whom they called Penates; which fee. And the Romish
church to this day, hold an opinion not much unlike it; they
believe that every perfon, at least every one of the faithful,
has, from the time of his birth, one of those tutelary an-
gels attached to his perfon, to defend him from all tempta-
tions; and it is on this, principally, that their practice of
invoking angels is founded.

F. Antony Macedo, a Portuguefe Jefuit of Coimbra, has
published a large work in folio on the tutelary fants of all
the kingdoms, provinces, and great cities of the Christian
world; " Divi Tutelares Orbis Christiani," at Liébon,
1678.

TUTELINA, or TUTILINA, in Mythology, the goddes of
corn, who had the care of it when depofited in the granary.
She had a chapel on the Aventine mount, and a flature in
the Circus.

TUTENAG, a name given in India to the femi-metal
zinc. It is also fometimes applied to denote a white metallic
compound, brought from China, called also Chenfe, or
white copper, the art of making which is not known in Eu-
rop.e. It is the bell imitation of silver which has been made:
it is very tough, fsorc, malleable, may be easily caf, ham-
mered, and polished; and the better kinds of it, when well
manufactured, are very white, and not more difpol'd to tarn-
ish than silver is.

Three ingredients of this composition may be discovered
by analysis, viz. copper, zinc, and iron. See Alleg of
Comptum.

TUTESERAL, in Geography, a town of Hindoostan,
in Lahore; 14 miles E.S.E. of Sultanpur.

TUTIA, or TUTILIA, in Ancient Geography, a town of
Hither Spain.

TUTICUM, a town of Italy, in Saminium, called in
the Itinerary of Antonine, " Equus Tuticus."

TUTLING, in Geography, a town of Bavaria; 10 miles
N. of Passau.

TUTOR, in the Civil Law, is one chosen to look to
the perfon and eflate of children left by their fathers and
mothers in their minority. See Guardian.

By the custom of Normandy, the father is the natural
tutor of his children. A perfon nominated tutor, either by
testament, or by the relations of the minor, is to decline that
office if he have five children alive; if he have any other
considerable tutorage; if he be under twenty-five years of
age; if he be a priest, or a regent in an university; or if he
have any law-fuit with the minors, &c.

The marriage of a pupil, without the consent of his
 tutor, is invalid. Tutors may do any thing for their pupils,
but nothing againft them; and the fame laws which put them
under a necelssity of preferring the interest of the minors,
put them under an incapacity of hurting them. See
Parent.

TUTOR, Honorary. See Honourary.

Tutor is also ufed in our universities for a member of
some college or hall, who takes on him the instruction of
young students in the arts and faculties.

TUTORAGE, TUTELA, in the Civil Law, a term
equivalent to guardianship in common law, signifying an
office imposed on any one, to take care of the perfon and
effeets of one or more minors. See Guardian.

By the Roman law there are three kinds of tutorage.
Testamentary, which is appointed by the father's testament.
Legal, which is given by the law to the nearest relation.
And dative, which is appointed by the magistrate.

But in all crumbling provinces, as France, &c. all tu-
torages are dative and elective; and though the father have
by testament nominated the next relation to his pupil, yet is
not that nomination of any force, unless the choice be con-
firmed by that of the magistrate, &c.

By the Roman law, tutorage expires at fourteen years of
age; but in France, not till twenty-five years. A minor
quits his tutorage, and becomes free by marriage; in which
case a curator is given him.

TUTOVA, in Geography, a river of Moldavia, which
runs into the Brilat, 4 miles S. of Brilat, in the province of
Moldavia.

TUTSAN, in Botony. See Hypericum.

TUTTI, in the Italian Muye, is ufed to signify that all
the parts are to play together, or to make a full concert.

In this fense, tutti flands oppofed to folo or fola.
It is often ufed exprefsed by annu, ripieno, ebual, &c.

Tuttu, in Geography, a town of Bengal; 13 miles
N.N.E. of Burraw.

TUTTLINGEN. See Duttingen.

TUTTUM, a town of Hindoostan, in Bundelcund; 20
miles N.E. of Chatterpore.

TUTTY, Tutia Alexandrina, or Lutia Tuita, an argu-
lacens ore of zinc, found in Peru, formed on cylindrical
mounds into tubulous pieces, like the bark of a tree, and
baked
TUX

baked to a moderate hardness. This account of its original is supported by the authority of Teixeira and Douglas, and by its chemical properties. That the common opinion of its being a fubliminate produced in the European founderies, where zinc is melted with other metals, is erroneous, appears from hence, that tutty is not found, upon strict enquiry, to be known at those founderies; and by its confitting, in a great part, of an earth not capable of rising in fublimation. This, however, is probable, that fublimates, or the common ores of zinc, are often mixed with argillaceous earths, and baked hard, in imitation of the genuine oriental tutty. Bontius, in his animadversions upon Garcias ab Orta, informs us, that it is made of a glutinous or argillaceous earth, like clay, found in great quantities in a province of Peria, called Kirman, which the Indians, who gather it, put into earthen pots made on purpose, and, adding water to it, stir it with a fick: these pots are then placed in furnaces till the water is evaporated; afterwards removing the dregs which remain at the bottom, they pick off from the fides of the pots the calcined earth or tutty, which they carefully preserve for sale. He adds, that it is used in India as a cosmetic for destroying hair, more efpecially by the women, when they bathe.

Tutty is generally of a brownish colour, and full of small protuberances on the outside, smooth and yellowish within, sometimes whitith, and sometimes with a blueish cast. Like other argillaceous bodies, it becomes harder in a strong fire; and after the zinc has been revived and diffipated by inflammable additions, or extracted by acids, the remaining earthy matter affords with oil of vitriol, an aluminous salt.

Tutty, levigated into an impalpable powder, is, like the lapis calaminaris and calces of zinc, an useful ophthalamic, and frequently used as such in ointments and collyria.

Ointments for this intention are prepared in the shops, by mixing the levitated tutty with fo much viper's fat as is sufficient to reduce it to due confluence, or, by adding one part to five parts of a simple liniment made of oil and wax.

See ZINC.

TUTUACA, in Geography, a town of Mexico, in the province of Hiaquil; 100 miles E. of Riochico.

TUTULUS, among the Romans, a manner of dressing the hair, by gathering it up on the forehead into the form of a tower.

TUTULUS likewise signifies a woollen cap with a high top.

TUTURA, in Geography, a town of Ruffia, in the government of Irkutsk, on the Lena; 160 miles N. of Irkutsk. N. lat. 44° 40'. E. long. 105° 44'.

TUTZIS, in Ancient Geography, a town of Egypt, between Tan湘 and Pticlia. Anton. Itin.

TUUVE, in Geography, a lake of Norway, about 20 miles in circumference; 52 miles from Christianfand.

TUXAL, a town of Hindoostan, in the circuit of Sirhind; 60 miles N.N.E. of Sirhind.

TUXFORD, a small market-town in South Clay division of the wapentake of Baffetlaw, in the county of Nottingham, England; is situated 24 miles N. by N. from the county-town, and 138 miles N. by W. from London. It was destroyed by fire September 8, 1702; consequently its appearance is more modern than that of many other towns in the county. Great part of it consists of farm-houses; agriculture being the chief employment of the inhabitants. Scarcely any trade is carried on here, except in hops, of which a considerable quantity is raised in this and the adjacent parishes. A fair for this is annually held in September; and another in May for cattle, sheep, pigs, and poultry. A weekly market on Mondays is well supplied in proportion to the population of the parish; which, in the return to parliament in the year 1811, is stated to be 841, occupying 197 houses. The church is an ancient structure, and consists of a nave, side-aisles, and chancel; with a spire. It contains the mutilated remains of monuments and other sculpture of a remote period. A rude representation of St. Lawrence on a gridiron is still entire; one man is employed in blowing the fire, another is turning the faint with tongs, and a third appears to be a spectator, or director. A free grammar-school, still in high repute, was founded, and liberally endowed, by the will of Mr. Charles Read, dated the 30th of July, 1699. A manuscript copy of the regulations, as contained in the will, is preserved in the British Museum.—History of Nottinghamshire, by J. Throffy, 3 vols. 4to. 1797. Beauties of England and Wales, vol. xii. Nottinghamshire.

TUXIUM, in Ancient Geography, a town of Italy, and capital of Samium. When Fabius Fabricianus pillaged this city, he removed the statue of the victorious Venus, worshipped here, to Rome. Plutarch.

TUX, in Geography, a town of Spain, in Galicia, situated on a mountain, near the north side of the Minho, opposite Valence, in Portugal; the seat of a bishop, suffragan of Compostella. In a war between Spain and Portugal, this is one of the places of rendezvous for the Spanish troops; 50 miles S. of Compostella. N. lat. 42° 3'. W. long. 8° 37'.

Tuy, a navigable river of Caraccas, which discharges itself into the ocean, 30 leagues E. of the port of Guayra. It rises in the mountains of San Pedro, 10 leagues from Caraccas, and being joined by the Guayra, becomes navigable, and serves for the transportation of produce, abound in the valleys of Aragoa, Taceta, Cus, Sabana, Ocumara, St. Lucia, and St. Thersea, through which it passes, and particularly caecus, which is here of the beet quality.

TUYU, a country of South America, in Patagonia, to the south of the viceroyalty of Buenos Ayres.

TUX-KURMA, a town of Curdiñan; 50 miles S.S.W. of Sherezur.

TUXLA, a town of Astatic Turkey, in Caramania, situated at the western extremity of a lake, to which it gives name. The lake is 36 miles in length, and about 4 in breadth; 28 miles N. of Cogni.—Alfo, a town of Astatic Turkey, in Natolia; 24 miles E. of Conflantimole.

TWAGER, a town of Sweden, in the province of Holland; 28 miles N.N.W. of Halmifd.

TWAITIE, in Ichthyology. See SHAD.

TWAITIE, in our Old Writers, a wood grubbed up and converted into arable land.

TWA-NIGHTS GESTE, in our Ancient Customs. See Third-night acen Hynde.

If the twa-night's geife did any harm to any, his hoft was not answerable for it, but himself.

TWARDONICE, in Geography. See Turnitz.

TWARSIMIRKA, a town of Silefia, in the principality of Oels; 6 miles N.E. of Militch.

TWASHTA, or TWASHIT, in the Mythology of the Hindoos, a name of the fun, or of its regent Surya. The name occurs as of the fun in the article SARASWATI. Other legends make Twashita the parent of Suranah, one of Surya's wives. In some points he corresponds with Vulcan, or Dedalus; being profoundly skilled in the mechanical arts, and hence deified in gratitude for his useful inventions. He seems to be the same personage with Vifwakarnas; being, like him, called the "chief engineer of the gods." Mr. Wilford's learned Essay on the sacred ifles of the Weft, in the
the eleventh volume of the Asiatic Researches, contains many curious particulars of this disfigured perfom, proving his identity with some western fable. See SuraunU, SuryA, and VrwikarmA.

TWAT, in Geography, a country of Africa, in the Great Desert. N. lat. 22° to 25°. E. long. 4° to 6°.

TWEDDA, a town of Sweden, in the province of Smalda; 42 miles N.N.W. of Calmar.

TWEDDS, a town of Norway, in the province of Christiansland; 4 miles N. of Christiansland.

TWEEED, a large river, which rises in the parish of Tweedsmuir, in the shire of Peebles, Scotland. It is remarkable, that from the base of the fame hill three large rivers have their source. The river Annan rises on its southern side, the Clyde on the north-west, and the Tweed on the north-east side. Taking a north-east direction, the Tweed runs a serpentine course of about forty miles through the county of Peebles. When it has reached the town of that name, which is about the centre of the shire, it has fallen nearly 1000 feet, as that town stands only about 500 feet above the level of the sea. In its course from Peebles, running nearly east, its stream is augmented by the Etterick near Selkirk, the Gala at Galashiels, the Leader near Melrose, and the Teviot at Kelso. A few miles below the latter town it leaves Roxburghshire, and forms, for 22 miles, the boundary between Berwickshire and England, till it falls into the German ocean at the town of Berwick: its whole course is 102 miles, being the longest river in the south of Scotland.

On the banks of the Tweed are many beautiful and romantic feats, embooned in plantations of various kinds of trees: but small are the vestiges that now remain of those extensive natural woods with which its banks were once adorned. Being near the southern borders of the kingdom, and exposed to the frequent incursions of the English, there is perhaps no river in Scotland, on the banks of which are to be seen so many places of defence against their hostile depredations. Still the ruins of castles and towers (as they are called) are visible; but they now only exhibit faint remains of their former magnitude, the wealth of their ancient inhabitants, and the deprecatory spirit which formerly prevailed. The Tweed abounds with trout of every species: the salmon-fishery was formerly very productive, but has been nearly destroyed through interred artifice. The Tweed is open to fishing from the 10th of January to the 10th of October. On this river, 41 different salmon fisheries have been rented for several thousand pounds a year. — Beauties of Scotland, vol. ii. Tweeddale, 1805. Chalmers’ Caledonia, vol. ii. 4to. 1810.

TWEEDEOUTH, a sea-port of England, in the county of Durham, separated only by the Tweed from Berwick. In 1811 the number of inhabitants was 5917.

TWEELEDING, an operation in weaving, which is performed by multiplying and varying the number of leaves in the harness; by the use of a back harness, or double harness; by increasing the number of threads in each split of the reed; by an endless variety of modes in drawing the yarns through the harness; and by increasing the number of tred- dles, and changing the manner of treading them. When the number of treddles requisite to raise all the variety of threds necessary to produce very extensive patterns would be more than one man could manage, recourse is had to a mode of mounting, or preparing the loom, by the application of cords, &c. to the harness; and a second person is necessary to raise the threds required, by pulling the strings attached to the respective leaves of the back harness, which are fast to their first position by means of leaden weights underneath.

Vol. XXXVI.

This is the most comprehensive apparatus used by weavers for fanciful patterns of great extent, and it is called the draw-loom. In weaving very fine silk twills, such as those of sixteen leaves, the number of threads drawn through each interval of the reed is so great, that, if woven with a single reed, this would obstruct each other in rising and sinking, and the thred would not be sufficiently open to allow the shuttle a free passage. To avoid this inconvenience, other reeds are placed behind that which strikes up the weft; and the warp threads are so disposed, that those which pass through the same interval in the first reed are divided in pas- sing through the second, and again in passing through the third. By these means the obstruction, if not entirely re- moved, is greatly softened.

In the weaving of plain thick woollen cloths, to prevent obstructions of this kind, arising from the closeness of the set, and roughness of the threads, only one-fourth of the warp is funk and raised by one treddle, and a second is pressed down to complete the thred, between the times when every half of weft is thrown across. See Weaving.

TWELFTH-HUND, in our Ancient Customs, imports much the same fame with thame.

Among the English Saxons, those who were worth 1200s. were called twelve-hurds; and if any injury was done to them, satisfaction was to be made accordingly. See Hinden.

TWELFTH-Day, or Twelth-sidé, the festival of the Epiphany, or the manifestation of Christ to the Gentiles, so called, as being the twelfth-day, exclusive, from the Nativity, or Christmas-day.

TWELVE MEND, duodecim homines legales, otherwise called jury, or inquisiti, is a number of twelve persons, or upwards, as far as twenty-four; by whose oath, as to matters of fact, all trials pass, both in civil and criminal cases, through all courts of the common law in this realm. See Jury.

TWELVE Tabels, Laxus of. See Table.

TWELVE APotles, in Geography, a number of small islands at the west extremity of the Straits of Magellan, on the coast of Terra del Fuego, between Cape Pillar and Cape Defeada.

TWELVE IFones, or Twelve Apotles, islands on the south side of lake Superior.

TWELVE Pinos, Thé, or Brannabola, a tall ridge of almost perpendicular rocks in the western part of the county of Galway, Ireland, called Cunneenara. These mountains belong to the primitive formation.

TWELVE-MILE CREEK, a river of South Carolina, which runs into the Saluda, N. lat. 34° 50'. W. long. 81° 16'.

TWELVE-MONTH, the space of a year, according to the calendar months.

TWENTE, in Geography, a district of the state of Overijssel, of which Oldenzel is the capital.

TWENTY-FOUR MEND, men chosen every half year to redress the grievances of the mines and miners; but every man generally serves his year when chosen.

TWENTY-MILE CREEK, in Geography, a branch of the river Tombighe, in Georgia.

TWICE-LAID Cordage, is made of call rigging, as shrouds, fles, mooring and other cables, which, if not much worn, will make good ropes, &c. for many purposes, as small cable-laid ropes for warping ships, warming and much worn for cables, warming for large fles, netting for fles’ fides, &c.; ratings, leaffolding-ropes, ffm-yarn for feizings, &c.

To open a cable for making it into small ropes, hang the 3 Q strand
frand upon three hooks in the tackle-board, stretch it out tight upon the hooks in the fledge, and have till they are untwisted; then draw out the yarn.

When the yarn of this worn stuff is overhand, a little thin tar should be poured upon it, which will make it pliable, and lie better. The yarn unit for knotting will pick into oakum for caulking.

TWICKENHAM, in Geography, an extensive and populous village in the hundred of Isleworth, and county of Middlesex, England; is situated on the banks of the river Thames, at the distance of twelve miles W.S.W. from St. Paul's cathedral, London. The parish extends about three miles and a half in length, one and a half in breadth, and is nine miles in circumference: it is bounded on the east and north by Isleworth, on the west by Hanworth, Hampton, and Teddington, and on the south by the river Thames. It contains about 1830 acres, of which, according to a survey taken in the year 1635, about 630 were arable, 450 pature, 40 wood, and 650 common: which does not much vary from the present proportion, reckoning the fruit gardens, of which there are above 150 acres, among the arable land. The gardens have long been celebrated for good management and abundant produce, and they afford a constant supply to the London markets: one gardener, Mr. Weft, has, in a good season, sent upwards of 4000 gallons of raspberries to a distiller within fifteen days. Twickenham is not mentioned in the Domesday record, as the whole of this hundred seems to have been included, when that survey was made, in the manor of Isleworth. In ancient records, the name is written Twitham, Twittanham, and Twickenham: and the most popular writers of the early part of the last century often termed it Twitvenham. The manor of Twickenham appears to have been possessed by the religious long antecedent to the Norman conquest; for the jurisdiction of the lord of Isleworth did not extend to church lands. This manor appears to have been vested in the crown in the time of Henry VIII., and by him annexed to the honor of Hampton-Court. By Charles I. it was settled as part of the jointure of his queen, on whose death, Charles II. settled it for his life, on his consort, Catherine. A lease under the crown has since been granted to several persons. The manor-house stands opposite to the church, and is traditionally said to have been the residence of Catherine of Aragon, the divorced queen of Henry VIII. The parli-church is situated near the river-side: the old church fell to the ground in the night of April 9, 1713; the tower, which is composed of freestone, is still remaining; the body was rebuilt, and completed in the year 1715. This is a brick fabric of the Tuscan order, with stone coigns and cornices, and was erected after the design of John James, architect, who likewise built the churches of St. George, Hanover-square, and St. Luke, Middlesex. The interior is spacious, with galleries on the two sides, and at the well end. The monuments, tables, and other sepulchral memorials, are numerous. A chapel, called Montpelier, was built about the year 1720, and is the private property of the Rev. G. O. Cambridge, archdeacon of Middlesex. Here is also a meeting-house for Wesleyan Methodists. A charity-school for boys, and a similar institution for girls, were established many years back: an extensive and appropriate building has been recently erected by subscription; and one hundred boys and seventy girls are now educated according to Dr. Bell's plan. Thirty of the boys, and twenty-four girls, are likewise clothed. Here are also two Sunday schools. Six almshouses were built in 1704, and six more in 1721. In the population return of the year 1711, this parish is stated to contain 685 houses, and 3757 inhabitants. The principal manufacture is that of gun-powder: the powder-mills, formerly the property of Mr. Hill, but now of Mr. Butts, are seated on the small river Crane, which, rising in the vicinity of Harrow, is here augmented by an artificial cut from the Colne. Accidents frequently occur in this dangerous business: one corning-house for grinding powder was twice blown up in the year 1795; in the months of January, July, and November. Fourteen lives were lost by the three explosions. Five similar explosions have since happened; and yet, notwithstanding the frequency of these accidents, and though the wages of the workmen is but small, employment in the mills is eagerly fought after: the only apparent reason is, that the labour is light.

Twickenham Park, Isleworth Park, or the New Park of Richmond, was, towards the end of the sixteenth century, the property of the great Sir Francis, afterwards lord, Bacon, who passed in this retirement the earlier and more happy part of his life. He here entertained queen Elizabeth, on which occasion he presented her with a fomat in praise of her favourite, the earl of Essex. The estate has recently been divided into lots, and the greater part purchased by Francis Golling, esq. The grounds contain some fine elms: and it is believed, that the first weeping willow known in this kingdom was planted in this park in the early part of the last century. Part of the mansion is in the parish of Isleworth: in the meadows, between this house and the river, was the original site of Sion monastery, founded by king Henry V. in 1414.

Twickenham has for a century past been the resort of person distinguished by their rank or literary fame; and there has been embellished with various mansions and villas, to which a degree of celebrity has attached. We shall briefly notice the most interesting.

Marble Hill was built by king George II. as a villa for his mistress, the countess of Suffolk. The purchase of the estate is said by lord Orford to have cost the king ten or twelve thousand pounds. The house was erected after a design of Henry, earl of Pembroke, who superintended the progress of the structure. Its exterior is of a plain but well-proportioned character; the interior contains the principal attractions, and is finished in a delicate, costly, and ornamental style. The great staircase is entirely composed of mahogany, finely carved; and the flooring of the ball rooms are of the same wood. This feat is now the residence of Charles Augustus, Earl Of Talbot, esq.

Pope's villa, as it has long been emphatically called, from its having been, for nearly thirty years, the residence of our great poet Alexander Pope, was purchased by him in the year 1715. The improvement of the house and gardens was for many years his favourite employment; and he was particularly interested in the construction of a grotto, which he enriched with many curious sars and gems; from the grotto was a subterraneous passage to the gardens. On the decease of Pope, which occurred May 30, 1744, the estate was sold to Sir William Stanhope, who added wings to the house and enlarged the gardens. From him it passed to his son-in-law, Welborne Ellis, afterwards lord Mends, who guarded every memorial of the poet as a sacred relic, particularly a fine willow planted by his own hand. This tree his lordship propped with affidious care, but notwithstanding his utmost attention, it perished and fell to the ground in 1801, about a year before the death of its noble owner. The estate was afterwards sold to sir John Hervey, and in 1807 purchased by baronets Hewett, under whose direction the house has been taken down, and a new dwelling erected about a hundred yards distant from the site. The grotto has been stripped of its most curious sars and minerals, by the zeal of those who wished
At Whiton, a hamlet in Twickenham parish, is a villa which was built about the year 1711 by Sir Godfrey Kneller, and was his principal residence during the latter part of his life. It is a substantial brick mansion, now the property of Mr. Calvert.

On the edge of Houndlow Heath, within this parish, are two villas of considerable elegance, formerly in the possession of Archibald, duke of Argyle, now occupied, one by Sir Benjamin Hobhouse, bart. the other by George Golling, eqq. — *Lyons’s Environos of London*, 5 vols. 4to. 1792—1811. *Beauties of England and Wales*, vol. x. Middlesex, by J. N. Brewer, 1816.

**TWIFALLOW**, in *Agriculture*, a term used to signify a second trifling or following of land.

**TWIFALLOWING**, the operation or work of repeating the tillage of land in following, which is mostly best performed about the middle of the summer. It is sometimes written twyfallowing.

**TWIGGS**, in *Geography*, a county of Georgia, in the United States, containing 3405 inhabitants.

**TWI-HINDI**, or *Twyhindi*, among our Saxon ancestors were men valued at 200. See *Hindeni*.

These men were of the lowest degree; and if such were killed, the mulct was 30s. In *Leg. Hen. I. cap. 9*, "de twihindi homines interdicti, vero debet reddi fecundum legem." Where note, that this was not an introduction of a new law, but a confirmation of the old, made in the reign of King Alfred.

**TWILIGHT**, in *Astronomy*, denotes the dubious or faint light which is reflected to us by means of the atmosphere, for some time before the sun rises, and after he sets. See *Crepusculum* and *Atmosphere*.

The following table shews the duration of twilight in different latitudes: it is calculated on a supposition that the twilight begins and ends when the sun is 18° below the horizon: the letters c. d. signify that it is then continual day; c. n. continual night; v. n. that the twilight lasts the whole night.

**TWIN**, in *Geography*, a township of Preble county, in the district of Ohio, containing 719 inhabitants.—Allo, a township of Ross county, in the same district, containing 1053 inhabitants.

**TWIN, North**, an island in James’s Bay, Hudson’s Bay. N. lat. 53° 20’. W. long. 86° 40’.

**TWIN, South**, an island in James’s Bay, Hudson’s Bay. N. lat. 52° 10’. W. long. 86° 36’.

**TWIN Oat**, in *Agriculture*, a name sometimes applied to an early kind of white oat, which is very productive on deep good land, and which affords full crops on most sorts that are not too poor in quality. It commonly yields somewhat more than the pollard oat. See *Oat*.

**TWINE.** *Bolt-ropc twine*, used in fewing falls to their bolt-ropc, is made of the long hemp, or from the long rough hemp unbeat. It contains two or three threads, is twisted fack, and wound into half-pound leams containing two hundred yards. Eight threads are spun out of half a pound of hemp, each fifty yards long.

**Seal-twine**, for seal-nets, is made of twelve threads, two threads first twined together, then fix of them hardended together, and wound up into half-shakes, or eighty yards.
TWI

Seeming or fail-maker's twine, for sewing the seams of fails, is made of the best long hemp, beated, spun fine, and well dressed over a fine clearer; eighteen threads are spun out of half a pound of hemp, every thread being fifty yards in length: two threads are twisted together slack, and wound on a reel, in half-pound strands containing four hundred and fifty yards: but twine of three threads is used in the navy.

Tendril-twine is made from good long hemp, each thread spun fifty-four yards: three threads are laid together. When hardened and stretched, each cord stands fifty yards; nine hundred yards are wound on a reel, and eighteen cords weigh two pounds.

Stores-twine, used by fail-makers for old work and on board of ships, is made from good long hemp, well dressed. Fourteen threads are spun from half a pound; two threads are twisted together, and wound into half-pound strands of three hundred and fifty yards.

Turtle-twine, for turtle-nets, is made of good bar hemp, spun one hundred yards; three threads are laid together, stand ninety yards, and weigh one pound.

Whipping-twine, the same as bolt-robe twine.

TWIX 

Iron's, square bars with an eye-hook at one end, which grasp the porter or the flark of an anchor to turn it over.

TWINKLING of the Stars, denotes that tremulous, vibratory, intermittently motion, which is observed in the light proceeding from the fixed stars: Alhazen, an Arabian philosopher of the twelfth century, considers reflection as the cause of this phenomenon.

Vitello, in his Optics, published in 1270, p. 449, ascribes the twinkling of the stars to the motion of the air in which the light is refracted; and he observes, in confirmation of this hypothesis, that they twinkle fill more when they are viewed in water put into motion.

Dr. Hooke (Microgr. p. 231, &c.) very reasonably attributes this phenomenon to the inconsistent and unequal refraction of the rays of light occasioned by the trembling motion of the air and interposed vapours, in consequence of variable degrees of heat and cold in the air, producing corresponding variations in its rarity or density, and also of the action of the wind, which must cause the successive rays to fall upon the eye in different directions, and consequently upon different parts of the retina at different times, and also to hit and miss the pupil alternately; and this is also the reason, he says, why the limbs of the sun, moon, and planets appear to wave or dance.

These tremors of the air are manifest to the eye by the tremulous motion of shadows cast from high towers; and by looking at objects through the smoke of a chimney, or through streams of hot water, or at objects situated beyond hot fands, especially if the air be moved transversely over them. But when stars are seen through telescopes that have large apertures, they twinkle but little, and sometimes not at all. For, as Sir Isaac Newton has observed, (Opt. p. 98.) the rays of light which pass through different parts of the aperture, tremble each of them apart, and by means of their various, and sometimes contrary tremors, fall at one and the same time upon different points in the bottom of the eye, and their trembling motions are too quick and confused to be separately perceived. And all these illuminated points constitute one broad lucid point, composed of those many trembling points confusedly and inextricably mixed with one another by very short and swift tremors, and thereby cause the star to appear broader than it is, and without any trembling of the whole.

Dr. Jurin, in his Essay upon Diffinition and Indiffinition, has recourse to Sir Isaac Newton's hypothesis of fits of easy refraction and reflection for explaining the twinkling of the stars: thus, he says, if the middle part of the image of a star be changed from light to dark, and the adjacent ring be at the same time changed from dark to light, as must happen from the least motion of the eye towards or from the star, this will occasion such an appearance as twinkling.

Mr. Michell (Phil. Trans. vol. viii. p. 262.) supposes that the arrival of fewer or more rays at one time, especially from the smaller or more remote fixed stars, may make such an unequal impression on the eye, as may, at least, have some share in producing this effect; since it may be supposed, that even a single particle of light is sufficient to make a sensible impression upon the organs of sight; so that a very few particles arriving at the eye in a second of time, perhaps not more than three or four, may be sufficient to make an object constantly visible. See Light.

Hence, he says, it is not improbable, that the number of the particles of light which enter the eye in a second of time, even from Sirius himself, may not exceed three of four thousand, and from stars of the second magnitude they may, therefore, probably not exceed a hundred. Now the apparent increase and diminution of the light, which we observe in the twinkling of the stars, seem to be repeated at not very unequal intervals, perhaps about four or five times in a second. He, therefore, thought it reasonable to suppose, that the inequalities which will naturally arise from the chance of the rays coming sometimes a little denser, and sometimes a little rarer; in so small a number of them, as must fall upon the eye in the fourth or fifth part of a second, may be sufficient to account for this appearance. An addition of two or three particles of light, or perhaps a single one, upon twenty, especially if there should be an equal deficiency, out of the next twenty, would, he supposed, be very sensible, as he thought was probable from the very great difference in the appearance of stars, the light of which does not differ so much as is commonly imagined. The light of the middlemost star in the tail of the Great Bear does not, he thinks, exceed the light of the very small star that is next to it, in a greater proportion than that of about 16 or 20 to 1: and M. Bouguer found, that a difference in the light of objects, of one part in sixty-six, was sufficiently distinguishable.

Since these observations were published, Mr. Michell (as we are informed by Dr. Prieifley, Hist. of Light, p. 459.) has entertained some suspicion, that the unequal density of light does not contribute to this effect in so great a degree as he had imagined; especially in consequence of observing that even Venus does sometimes twinkle. This he once observed her to do remarkably when she was about five degrees high, though Jupiter, which was then about sixteen degrees high, and was faintly less luminous, did not twinkle at all. If, notwithstanding the great number of rays, which, without doubt, come to the eye from such a surface as this planet presents, its appearance be liable to be affected in this manner, it must be owing to such undulations in the atmosphere, as will probably render the effect of every other cause altogether inappreciable.

M. Mufchenbroeck (Introd. ad Phil. Nat. vol. ii. sect. 1741, p. 707.) supposes, that the twinkling of the stars arises from some affection of the eye, as well as the state of the atmosphere. For, he says, that in Holland, when the weather is frosty, and the sky very clear, the stars twinkle most manifestly to the naked eye, though not in telescopes; and since he does not suppose there is any great exhalation, or dancing of the vapour at that time, he questions whether the vivacity of the light, affecting the eye, may not be concerned in the phenomenon.
But this philosopher might have satisfied himself with respect to this hypothesis, by looking at the stars near the zenith, when the light travels but a small part of the atmosphere, and therefore might be expected to affect the eye most sensibly. For he would not have perceived them to twinkle near so much as they do near the horizon, when much more of their light is intercepted by the atmosphere.

Some astronomers have lately endeavoured to explain the twinkling of the fixed stars, by the extreme minuteness of their apparent diameter; so that they suppose the light of them is intercepted by every mote that floats in the air.

To this purpose Dr. Long observes (Astron. vol. i. p. 170.) that our air near the earth is so full of various kinds of particles, which are in continual motion, that some one or other of them is perpetually passing between us and any star which we look at, and this makes us every moment alternately fee it and lose sight of it: and this twinkling of the stars, he says, is greatest in those which are nearest the horizon, because they are viewed through a great quantity of thick air, where the intercepting particles are most numerous; whereas stars that are near the zenith do not twinkle so much, because we do not look at them through so much thick air, and therefore the intercepting particles being fewer, come less frequently before them.

With respect to the planets, it is observed, that they, because they are much nearer to us than the stars, have a sensible apparent magnitude, so that they are not covered by the small particles floating in the atmosphere, and therefore do not twinkle, but shine with a steady light. The fallacy of this hypothesis appears from the observation of Mr. Michell, that no object can hide a star from us that is not large enough to exceed the apparent diameter of the star, by the diameter of the pupil of the eye; so that if a star was a mathematical point, the intercepting object must fill in equal size to the pupil of the eye: and, indeed, it must be large enough to hide the star from both eyes at the same time.

The principal cause, therefore, of the twinkling of the stars is now acknowledged to be, the unequal refraction of light, in consequence of inequalities and undulations in the atmosphere.

Besides a variation in the quantity of light, it may here be added, that a momentary change of colour has likewise been observed in some of the fixed stars. Mr. Melville (Edinb. Eff. vol. ii. p. 81.) says, that when one looks steadfastly at Sirius, or any bright star, not much elevated above the horizon, its colour seems not to be constantly white, but appears tinted, at every twinkling, with red and blue. Mr. Melville could not entirely satisfy himself as to the cause of this phenomenon; observing, that the separation of the colours by the refractive power of the atmosphere is, probably, too small to be perceived. Mr. Michell's hypothesis above-mentioned, though inadequate to the explanation of the twinkling of the stars, may pretty well account for this circumstance. For the red and blue rays being much fewer than those of the intermediate colours, and therefore much more liable to inequalities, from the common effect of chance, a small excess or defect in either of them, will make a very sensible difference in the colour of the stars.

TWINS, two young ones delivered at a birth by an animal which ordinarily brings forth but one. It has been greatly disfigured, which of two twins is to be esteemed the elder? The faculty of Montpellier have given it, that the latter born is to be reputed the elder, because first conceived: but by all the laws which now obtain, the first-born enjoys the privilege of seniority; and the custom is confirmed by the scripture instance of Esau and Jacob.

But if two twins be born so intermixed, that one cannot distinguish which of the two appeared first, it should seem that neither the one nor the other can pretend to the right of primogeniture, which ought to remain in suspense by reason of their mutual concourse. In such case, some would have the decision left to the father, and others to the chance of a lot.

In cattle, twins are seldom desirable, as they can rarely be well supported, though occasionally cows are capable of suckling two calves; but in sheep, it is often greatly desirable in different breeds or varieties. The frequency of twins in sheep is much influenced both by the condition of the ewes, and the state of vigour in the rams. Such flocks as are well fed, and pasture easily about the tapping time, usually produce a far larger proportion of twins, than those which have higher walks, or pastures which are of inferior quality. Twins too are the most frequent in the early part of the lambing season: all which shew the propriety of keeping the ewes well supplied, and of not letting the rams have too great a number put to them at such feasons.

Nice attention is necessary to twins at the time of lambing, by the person who has the charge of the business, to see that they are in every way properly taken care of.

TWINS, in Astronomy. See Gemini.

TWINS, in Geography, two small islands in the East Indian sea, near the island of Paraguay. N. lat. 9° 18'. E. long. 118° 3'.—Alfo, two small islands in the East Indian sea, near the north coast of the island of Flores. S. lat. 8° 2'. E. long. 122° 33'.

TWIST of a Rope, Cord, &c. See Rope.

TWIST, again, is used for the inside, or flat part of a man's thigh, upon which a true horsemann rides when on horseback.

TWIST a Horse, To, is violently to wind or twist his testicles twice about, which causes them to dry up, and deprives them of nourishment, and reduces the horse to the same state of impotency with a gelding.

TWISTE, in Geography, a river of Germany, which runs into the Erpe, near Valeckmarfen, in the duchy of Westphalia.

TWISTED COLUMN. See Column.

TWISTED Silks. See Silk.

TWISTED Thumb-Band, in Rural Economy, a term used to signify the band of hay or straw which is formed by means of the thumb and fingers, by twisting it with them, and employed in binding up trusses of these kinds for sale. See Truss.

TWITCH, in Agriculture, a name often applied to a very troublesome plant of the weed kind in tillage-land, of which there are several sorts, as the black, white, creeping, and some others. See Couch-Graft.

TWITCH-Rake, a name sometimes applied to a large tool of this kind, made use of in dragging and collecting the roots of couch together in arable land, by means of a horse. See Couch and Rake.

TWITE, in Ornithology. See Linnet.

TWO Brothers, in Geography, two small islands in the Chinefe sea. N. lat. 8° 30'. E. long. 105° 48'.—Alfo, two small islands in the East Indian sea, near the W. coast of Borneo. S. lat. 1° 32'. E. long. 109° 13'.—Alfo, two small islands in the East Indian sea, 27 miles from the E. point of the island of Madura. S. lat. 6° 50'. E. long. 114° 43'.—Alfo, two small islands in the East Indian
Two-Head Island, a small island near the S. coast of Ireland, and county of Kerry; 1 mile W. of Lamb's Head.  

Two-Headed Points, a cape on the S.W. coast of the island of Kodiak, in the North Pacific ocean, comprising a small island, which terminates to the N.E. by a low flat rocky point. South-westward from Two-headed Island the coast is low, and appears to be compact; but immediately to the northward of it, the shores descend abruptly into the sea, appear to be much broken, and form an extensive found, of which the flat rocky point may be considered as its S.W. point of entrance; from this, its N.E. point being low projecting land, lies N. 58° E. at the distance of nine miles. The several branches that appeared to flow into the Sound, seemed to wind toward the base of a connected group of high rocky mountains, which no doubt gave boundaries to their extent. N. lat. 56° 54'. E. long. 207° 5'.

Two Hills, a small island among the New Hebrides, in the South Pacific ocean. S. lat. 17° 15'. E. long. 166° 38'.

Two-Hill Island, a small island in the Mergui Archipelago. N. lat. 11° 27'.

Two Keys, two small islands in the bay of Honduras. N. lat. 17° 30'. W. long. 87° 52'.

Two-Saddle Island, an island in the Mergui Archipelago, about four miles long, and two broad. N. lat. 10° 42'.

Two Sifers, two small islands in the East Indian sea, covered with wood, and surrounded by a reef of coral rocks. S. lat. 5°. E. long. 106° 12'.—Alfo, two small islands in the Spanish main, near the Mosquito shore. N. lat. 11° 17'. W. long. 82° 55'.

Two Spots, small islands in the bay of Honduras, surrounded with rocks. N. lat. 16° 40'. W. long. 88° 20'.

TWOBILL, in Agriculture, the name of a tool commonly employed in cutting up roots in the work of paring and burning in the old mode. It is seen in fig. 7, in the plate on paring ploughs. It has sometimes the title of double-bitted mattock.

TWO-FURROW PLOUGH, a term sometimes applied to that of the double kind. It is often useful for cross-cutting land in different cafes, and in giving the last earth for turnip-crops.

TWO-FURROWING, a term used to signify double furrows, or the breaking up land by the double plough: it also implies trench-ploughing and sod-burying.

TWO-MEAL CHEESE, in Rural Economy, a term applied to that sort which is made from the skimmed milk of the evening, added to the new milk of the meal of the morning; that made from the next milk being termed one-meal. In some districts, as that of Gloucester, two-meal cheese is made of one meal or portion of coward or clean milk, and the fame of fuc. 35 is skimmed; but often two of the latter are used to one of the former. Hence this fort is sometimes called coward-cheese.

TWO-MOULD-BOARDED Cleaning and Earthing Hoe for Potatoes, in Agriculture, a tool of somewhat the plough kind, contrived for the purpose of cleaning and earthing up thee crops with. It has a wheel before to direct the depth of its working, with handles behind to regulate it. There is a sharp hoe attached to a fort of coulter-bar in front, with a mould-board on each side, capable of being let to different distances, by a kind of ferew in the middle, by which means the ground is pared and laid to the crops. It is considered a tool that produces much saving and advantage in the culture of potatos, and which performs its work very effectually.

TWO-PENCE, in Botany, a species of Lyssmachia, which fec.

TWO-THIRDS SUBSIDY. See Duty and Subsidy.

TWPUNT, in Geography, a town of Algiers, on the coast of the Mediterranean, defended by a fort; 30 miles N.W. of Tremecen. N. lat. 35° 18'. W. long. 1° 2'.

TWYBLADE, in Botany. See Ophiurus.

TYACUL, in Geography, a town of Hindooofian, in Myore; 10 miles S. of Colar.

TYAHTATOOA BAY, a bay on the coast of Owhyhee, one of the Sandwich iflands. N. lat. 19° 37'. E. long. 203° 54'.

TYANA, in Ancient Geography, a town of Cappadocia, in the Tyannidit prefecture; the only one in this prefecture, according to Strabo; but according to Ptolemy, there were three others. It was known as the native country of Apollonius Tyanaus, the celebrated impostor.

TYANA, in Geography, a town of Aflatic Turkey, in Natalo; 25 miles S.W. of Isis.

TYBEL, an ifland near the coast of Georgia, at the mouth of the Savanna: on it is a light-houfe. N. lat. 32°. W. long. 81°.

TYBEIN, See Dinuo.

TYBER, See Tibetans and Tyberinus. The Tyber appears on the reverse of a medal of Vepafaian, not only as a divinity, but also as the patron and protector of Rome. When Æneas refided in Italy, he performed religious ceremonies to this river, gave himself up to his protection, and prayed that he might be propitious to him.

TYBERINUS, a king of Alba, and from this prince having drowned himself in the Albuca, that river gained the name of Tyber, which it has ever since retained.

TYBOINE, in Geography, a township of Pennsylvania; 100 miles W. of Philadelphia.

TYCHE, in Ancient Geography. See Syracuse.

TYCHONIC Systen, or Hypothefis, is an order or arrangement of the heavenly bodies, of an intermediate nature between the Copernican and Ptolemaic, or participating alike of them both. See System.

TYDAL, in Geography. See Reden.

TYDII, in Ancient Geography, a people of Aflatic Saratia, who inhabited mount Caucafaus, according to Pliny.

TYE, Dr. in Biography, the beft English compofe of church music, anterior to Tallis, that our country can boast; for though his name does not appear in the lift of musicians of the chapel royal, or household establishment in the short reign of Edward VI., he was, doubtless, at the head of all ecclefiafal compofers of that period. Neither the state of the church, nor religious principles of its nominal members, were fo settled as to render it possible to determine, in these times, who among quiet and obedient subjects were Protetants, and who Catholics; for, during the conflict between the zealous of both religions, the changes were fo violent and rapid, that great flexibility or great
great diffimulation must have been practised by those who not only escaped persecution, but still continued in offices, either of church or state. The few who seem to have been truly pious and conscientious on both sides, suffered martyrdom in support of their opinions; the rest seem to have been either uncompromised, or fluctuating between the two religions. One of the principal evils which the champions for reformation combated, was the use of the Latin language in the service of the church; however, the best choral compositions produced by the masters of these times, that are come down to us, are to Latin words. Specimens remain of Dr. Tye's clear and masterly manner of composing for the church in that language, when he was at least a nominal Catholic, either during the reign of Henry VIII. or queen Mary; and the late worthy Dr. Boyce has given an admirable example of his abilities in the anthem for four voices, "I will exalt thee, O Lord," inferted in the second volume of his excellent "Collection of Cathedral Music, by English Masters." There is hardly any imitative to be found in the productions of composers for the church during his time, of a piece so conversant and regularly in any one key, as this is in the key of C minor, and its relatives; the harmony is pure and graceful; the time and melody, though not so marked and accented as in those of the best compositions of the last century, are free from pedantry, and the difficulty of complicated measures which this composer had the merit of being one of the first to abandon. That he translated the first fourteen chapters of the Acts of the Apostles into metre, in imitation of Sternhold's Psalms, which were the delight of the court in which he lived, was doubtless an absurd undertaking, and was not rendered less ridiculous by the elaborate music to which he fitted them, conforting of fugues and canons of the most artificial and complicated kind. Dr. Tye, however, if compared with his contemporaries, was perhaps as good a poet as Sternhold, and as great a musician as Europe could then boast; and it is hardly fair to expect more perfection from him, or to blame an individual for the general defects of the age in which he lived.

Tye, in Geography, a river of Virginia, which runs into James river, N. lat. 37° 30'. W. long. 79° 8'.

Tye, in Mining. See STREAMING.

Tye, in Sea Language, denotes a sort of runner, or thick rope, used to transmit the effort of a tackle to any yard or gaff, which extends the upper part of a fall.

The tye is either passed through a block fixed to the maff-head, and afterwards through another block moveable upon the yard or gaff intended to be hoisted; or the end of it simply fastened to the fall, yard, or gaff, after communicating with the block at the maff-head. Falconer. See JERS.

TYE, in Geography, a river of South Carolina, which runs into the Cangaree, N. lat. 34° 30'. W. long. 81° 45'.

TYERS, JONATHAN, in Biography, the late proprietor, and indeed the creator of Vauxhall gardens, (see VAUXHALL,) deserves a place among our biographical articles on many accounts. His taste, liberality, and spirit in supporting and ornamenting this elegant place of amusement with paintings by Hogarth and Hayman; an excellent band of music; an orchestra in the form of a temple in the open air, with an organ equal in size and workmanship to many of the most noble instruments of that kind in our churches; and a continual succession of ingenious exhibitions; rendered it a public place more attractive, admired, and imitated by foreigners, than any one our country could boast. In every part of Europe a nominal Vauxhall has been established; nor was there a theatre on the continent thirty years ago, with scenery and ballet pantomimes, without an attempt at representing Vauxhall.

The proprietor began with a small band of wind-instruments only, before he erected an orchestra, and furnished it with an organ; but in the summer of 1745, to render it still more attractive, he added, for the first time, vocal to his instrumental performances. Here the talents of many of our national musicians were first displayed and first encouraged; here Collet and Pinto on the violin, Snow on the trumpet, Millar on the basset, Worgan on the organ, &c. annually increased in merit and favour. Here Meffrs. Arne, Lowe, and the elder Reinhold sung during many years, with great applause, Dr. Arne's ballads, duets, dialogues, and trios, which were soon after circulated throughout the kingdom, to the great improvement of our national taste. During this first summer, his little dialogue of Colin and Phoebe, written by the late Mr. Moore, author of "Fables for the Female Sex," was constantly encored every night for more than three months successively.

But here the good sense, sound judgment, and good taste of the spirited proprietor of Vauxhall, appear to be看得 for the veneration and respect which he manifested for Handel; at a time when the health and favour of this great master were on the decline, and opposition had almost ruined him: it was then that Tyers erected, at his sole expense, the marble statue which still adorns the gardens; an honour which has seldom been conferred on a subject and a professional man, during his life-time, in any country, since the flourishing state of the Greeks and Romans. And as this transfaction does honour, not only to the genius of Handel, but to the public spirit of his votary, we shall relate it as recorded in the registers of the times.

April 15th, 1738, in the London Daily Post, a paragraph says: "The effigies of Mr. Handel, the famous composer of music, is going to be erected at Vauxhall gardens, at the expense of Mr. Jonathan Tyers." And on the 18th of the same month, "We are informed, from very good authority, that there is now near finished a statue of the justly celebrated Mr. Handel, exquisitely done by the ingenious Messrs. Roubillac, of St. Martin's-lane, statuary, out of one entire block of marble, which is to be placed in a grand niche, erected on purpose in the great grove at Vauxhall gardens, at the sole expense of Mr. Tyers, conductor of the entertainments there; who, in consideration of the real merit of that inimitable master, thought it just and proper that his effigies should preside in that place, where his harmony has so often charmed even the greatest crowds into the most profound silence and attention. It is believed, that the expense of the statue and niche cannot cost less than 300l.; the said gentleman, likewise, very generously took at Mr. Handel's benefit, fifty of his tickets."

May 2d, we have a farther account of this species of apotheosis, or laudable idolatry, in the following words: "Last night at the opening of the Spring-gardens Vauxhall, the company expressed great satisfaction at the marble statue of Mr. Handel, who is represented in a loofe robe, sweeping the lyre, and listening to its sounds; which a little boy sculptured at his feet seems to be writing down on the back of a violoncello. The whole composition is in an elegant taste."

Soon after, the following verses appeared:

"That Orpheus moved a grove, a rock, or stream,
By music's power, will not a fiction seem?
For here as great a miracle is shown—
A Handel breathing, though transform'd to stone."

TYFORY,
TYFORY, in Geography, a small island in the East Indian sea; 45 miles W. of Giliolo. N. lat. 1° 6'. E. long. 126° 28'.

TYGART'S VALLEY, a district of Pennsylvania, watered by the Monongahela river.

TYGER, in Zoology. See Tigern.

Tyger, in Geography, a river of South Carolina, which joins the Saluda, 5 miles N. of Columbia; and both together form the Congaree.

Tyger's Point, a cape of Afa, on the south-west coast of Ava, at the mouth of the Perfain. N. lat. 15° 50'. E. long. 94° 45'.

Tyger's Creek, a river of Kentucky, which runs into the Ohio, N. lat. 38° 22'. W. long. 83'.

Tyger's Island, a small island in the Chinefe sea, near the coast of Chiampa. N. lat. 10° 47'. E. long. 107° 45'. —Also, a small island in the Chinefe sea, near the coast of Cochinchina. N. lat. 16° 51'. E. long. 106° 13'.

Tyger Island, a small island in the Pacific Ocean, at the entrance of the bay of Amapalla. N. lat. 13° 10'.

Tyger Islands, a cluster of small islands and shoals in the East Indian sea; 30 miles E. from the island of Saleyer.

TY-GWYN, a village of South Wales, in the county of Caermarthen, where Howel Dha, first monarch of all Wales, had a palace: and in the year 942, a council was held, to form a body of laws. On this spot a Celtic temple was founded, called Whetfand Abbey; 5 miles W. of St. Clare.

TYING, in Music. See Legate-Note and Syncope.

TYKOCZYNS, in Geography, a town of Poland, in the palace of Bielk. In 1705, Augustus II. instituted the order of the White Eagle in this town; 28 miles N.W. of Bielk.

TYLANGIUM, in Ancient Geography, a town of the Peloponnesus, in Tribylia, according to Polybius.

TYLE, or Tile, in Building, a fort of thin, factitious, laminated brick, used on the roofs of houses, or more properly, a kind of flat clayey earth, kneaded and moulded of a Jut thicknes, dried and burnt in a kiln, like a brick, and used in the covering and paining of houses.

It is thus called from the French tuille, of the Latin tegula, which signifies the same.

Tiles are made, says Mr. Lelyburn, of better earth than brick-earth, and something near akin to the potter's earth.

By 17 Geo. III. c. 42, all combinations for enhancing the price of tiles and bricks, shall be void; and every tylemaker, or brick-maker, offending, shall forfeit 20l. and every clerk, agent, or servant, 10l.; half to the poor, and half to him who sues within fix calendar months.

By 43 Geo. III. c. 69, schedule (A.) and the 45 Geo. III. c. 32, in lieu of any duties of excise then subfizing, new duties were imposed.

The said duties on bricks and tyles to be paid by the maker or makers thereof respectively.

For the duties on exportation and importation, see the schedules annexed to the said act of 43 Geo. III. c. 69.

Provided always, that tyles made for the sole purpose of draining land, 19½ inches long by 13½ inches broad, and bent into a semi-elliptical form, the infide of the crown of the arch thereof being not less than seven inches perpendicular, from a straignt line drawn from the one to the other side thereof after the fame is fo bent, and such fides not being at any part thereof more than five inches dffant from each other on the infide, and as nearly of the dimenfion, and bent as nearly into the form aforesaid as may be, to be used for the purpofes aforesaid, shall not be fubjeft to any of the faid duties. 34 Geo. III. c. 15.—And the exemption is extended to tyles made for fuch purpofe not lefs than nine inches long; such being in every other repect of the fame description and dimenion as before preferred. 42 Geo. III. c. 93.

And by the 46 Geo. III. c. 138, it is further enacted, that ifemi-elliptic tyles not exceeding in infide width fix inches, and the height of which from the outside of the crown of the arch in a perpendicular line to the extreme edge shall in all cafes exceed the width, but with a foot from the bottom of the arch where neceffary, not exceeding two inches in breadth, made for draining wet or marfly lands, are exempted from the excize duty.

And any person using any fuch tyle for any other purpofe than above-mentioned, incurs the penalty of 6d. each ftye so used.

And every maker of bricks or tyles, before he begins to make, fhall leave or give notice in writing at the next excize office of his name and place of abode, and of the fhefs, workhoufes, or other places where fuch bricks or tyles are intended to be made; on pain of 100l. 24 Geo. III. c. 24. feff. 2.

All bricks and tyles chargeable with the said duties fhall be taken account of and charged by the officer whifft they are drying, after being turned out of the moulds, and before removed to the kiln or clamp for burning, for which purpose any officer may enter into the fields, fhefs, or other places where making, and fhall take an account thereof in writing, and leave a copy (if demanded) with fuch officer, on pain of 40l.: and if any person fhall obstruct fuch officer, he fhall forfeit 50l.

The officer charging the duty fhall allow ten for every hundred when charged in the field before burned, in compenfation for all waft, los or damages.

And if the maker fhall remove any bricks or tyles to the kiln or clamp or other place of burning from out of the field or place where they fhall be put or placed to dry before the officer fhall have taken an account thereof, he fhall forfeit 50l. And all fo carried away, and found in the poffeffion of any maker, or trader therein, or perfon for his use, fhall be forfeited and may be feized, or the value thereof fhall be forfeited. 25 Geo. III. c. 66.

Provided, that no fuch maker fhall be fubjeft to the faid penalty, if the officer fhall fail to take an account, on due notice given him three days before fuch removal. 24 Geo. III. c. 24. feff. 2.

The maker fhall keep the bricks and tyles unsurveyed separate from thofe that have been surveyed; on pain of forfeiting 50l. 25 Geo. III. c. 66.

And fuch maker fhall, while the fame are drying, place them in fuch manner as the officer may callly and securely take an account thereof; and if he fhall place them in an irregular or unusual manner, with intent to make it difficult or unsafe for the officer to take fuch account, he fhall forfeit 50l.

If any maker fhall fraudulently conceal or hide any bricks or tyles in any part of the operation of making, with intent to evade the duties, he fhall forfeit the fame, and also 20l. 24 Geo. III. c. 24. feff. 2.

Every fuch maker fhall once in every fix weeks make entry in writing upon his oath, or on the oath of his chief workman, at the next excize office, of all bricks and tyles by him made within that time, on pain of 50l. And fhall also, within six weeks after fuch entry, clear off all the duties then due thereon; on pain of double duty. And if any perfon fhall carry away, fuch bricks or tyles before the duty be cleared off, he fhall forfeit double the value thereof. But fuch
Tyl

such maker shall not for making such entry be obliged to go further than the next market-town.

And all tools, implements, and utensils used in making such bricks or tyles, in custody of the maker, &c. shall be liable to be forfeited for any debts or penalties, (arising or incurred under this act,) whether the debtor or offender be the lawful owner thereof or not. 28 Geo. III. c. 37.

Bricks or tyles for which the duties have been paid may be exported, and on security given before the shipping thereof, that the same shall not be relanded, the person exporting the same shall be allowed a drawback of such duties; and in case such bricks or tyles shall be relanded, the same shall be forfeited to the use of his majesty, over and above the penalty of such bond. 27 Geo. III. c. 13. seded. (F.)

All penalties and forfeitures are to be sued for, levied, and mitigated as by the laws of excise, or in the courts at Westminster, and to be distributed half to the king, and half to him that shall sue. 24 Geo. III. c. 24. sect. 2.

For the method of burning tyes, see Batec.

As to the applying of tyles, some lay them dry, as they come from the kiln, without mortar, or any thing else; others lay them in a kind of mortar made of loam and horse-dung. In some parts, as in Kent, they lay them in mors.

There are various kinds of tyles for the various occasions of building; as plain, thick, ridge, roof, croasf, gutter, pan, crooked, Flemifh, corner, hip, dorman or dormar, fealop, afferagal, traverss, paving, and Dutch tyles.

Tyles, Plain or Thick, are those in ordinary use for the covering of houses. They are fqueezed flat, white yet soft, in a mould. They are of an oblong figure, and by flat. 17 Edw. IV. c. 4. are to be ten inches and a half long, fix and a quarter broad, and half an inch and half a quarter thick. But these dimensions are not strictly observed.

Plain tyles are not laid in mortar, but only pointed in the inside.

Tyles, Ridge, Roof, or Croasf, are those used to cover the ridges of houses, being made circular, broadwise, like a guill cylinder. These are what Pliny calls latercular, and are by statute to be thirteen inches long, and of the same thick-nesses with the plain tyles.

Tyles, Hip or Corner, are those which lie on the hips or corners of roofs. As to form, they are first made flat, like plain tyles, but of a quadrangular figure, whose two sides are right lines, and two ends arcs of circles; one end being a little concave, and the other convex. The convex end is to be about seven times as broad as the concave end; so that they would be triangular, but that one corner is taken off; then, before they are burnt, they are bent on a mould, broadwise, like ridge tyles. They have a hole at their narrow end to nail them on by, and are laid with their narrow end upwards. By statute, they are to be ten inches and a half long, and of a convenient breadth and thickness.

These, as well as the ridge tyles, are to be laid in mortar, because they seldom lie so close as to admit any water to pass between them.

Tyles, Gutter, are those which lie in gutters or valleys in croasf-buildings. They are made like corner tyles, only the corners of the broad end are turned back again with two wings. They have no holes in them, but are laid with the broad end upwards, without any nailing. They are made in the same mould as corner tyles, and have the fame dimensions on the convex sides. Their wings are each four inches broad, and eight long.

These tyles are seldom used where lead is to be had.

Tyles, Pan, Crooked, or Flemifh, are used in covering Vol. XXXVI.

of sheds, stables, out-houses, and all kinds of flat-roofed buildings. They are in form of an oblong parallelogram, as plain tyles, but are bent breadthwise forwards and backwards, in the form of an S, only one of the arches is at least three times as big as the other, which biggest arch is always laid uppermost, and the left arch of another tyle lies over the edge of the great arch of the former. They have no holes for pins, but hang on the laths by a knot of their own earth. By 17 Geo. III. c. 42. they are to be, when burnt, not less than thirteen inches and a half long, nine and a half inches wide, and half an inch thick, on pain that the maker shall forfeit 10d. for every 1000.

Pan-tyles are laid in mortar, because the roof being flat, and many tyles being warped in the burning, they will not cover the roof so well as that no water pails between them.

Tyles, Dormar or Dormar, consist of a plain tyle, and a triangular piece of a plain one, standing up at right angles to one side of the plain tyle, and swept with an arc of a circle from the one end, which end terminates in a point. Of these tyles there are two kinds; the triangular piece, in some, standing on the right, in others on the left side of the plain tyle. And of each of these, again, there are two kinds, some having a whole plain tyle, others but half a plain tyle. But in them all, the plain tyle has two holes for the pins, at that end where the broad end of the triangular piece stands.

Their use is to be laid in the gutters, between the roof and the cheeks or fides of the dormars, the plain part lying on the roof, and the triangular part standing perpendicular by the cheek of the dormar. They are excellent to keep out the wet in those places, and yet they are hardly known any where but in Suffex. The dimensions of the plain tyle part are the same as those of a plain tyle, and the triangular part is of the same length, and its breadth at one end seven inches, and at the other nothing.

Tyles, Staleop or Afferagal, are, in all respects, like plain tyles, only their lower ends are in form of an afferagal, viz., a semicircle, with a square on each side. They are used in some places for weather tylings.

Tyles, Traverss, are a kind of irregular plain tyles, having the pin-holes broken out, or one of the lower corners broken off. These are laid with the broken end upwards, upon the rafters, where pinned tiles cannot hang.

Tyles, Flemifh or Dutch, are of two kinds, ancient and modern. The ancient were used for chimney foot-paces; they were painted with antique figures, and frequently with poruffles of soldiers, fome with compartments, and fome with morefque devices; but they came greatly short, both as to the design and colours, of the modern ones.

The modern Flemifh tyles are commonly used plastered up in the jambs of chimneys, instead of chimney corner- flones. These are better glazed, and fuch as are painted (for fome are only white) are much better performed than the ancient ones.

But both kinds seem to be made of the fame whitifh clay as our white-glazed earthenware. The ancient ones are five inches and a quarter square, and about three-quarters of an inch thick; the modern ones six inches and a half square, and three-quarters of an inch thick.

When these tyles are set with good mortar they lock beautiful, and call a greater heat than fome; for, being very smooth and glazed, the rays of heat striking upon them are all reflected into the work, especially when the fides of the chimneys are oblique, or in the form of circular arches. But they are little used.

Tylings is measured by a square of 100 square feet; and the number of tyles required for such a square depends on R
TYL

the distance of the laths, which, when six inches, requires 800; when six and a half inches, 740; when seven inches, 690; when seven and a half inches, 640; and when eight inches, 600 yoles.

TYLE, in Atticizing. See Tile.

TYLER, one that covers or paves with tiles.

Tylers and bricklayers were incorporated into Eliz. under the name of "Master and Wardens of the Society of Freemasons of the Mystery and Art of Tylers and Bricklayers." See Company.

Tylers, Great, in Geography, a small island in the Gulf of Finland. N. lat. 59° 50'. E. long. 27° 12'.

Tylers, Little, a small island in the Gulf of Finland. N. lat. 59° 48'. E. long. 26° 54'.

TYLERY. See TELLERIE.

TYLIS, in Ancient Geography, a town of Thrace, on mount Helmus.

The plants of this genus have twining, either herbaceous or shrubby, stems. Leaves opposite, membranous, flat. Umbels standing between the footstalks. Flowers for the most part small. Four of the species are natives of New Holland, chiefly within the tropic, but extending as far as thirty-three degrees of south latitude. As many are found either in the East Indies or the equinoctial parts of Africa, but of these four latter, none of them described in any botanical work, the learned author has favoured us with no account. We can therefore merely give the characters of the New-Holland species, from his Prodromus. It only remains for us to observe, that Tylophora comes very near Hoya, see that article, differing scarcely in any part of the essential character, except the want of a tooth at the inner angle of each leaf of the crown; and with respect to habit, distinguished from one only of the two species of that genus, by having membranous, not fleshy, leaves.

1. T. grandiflora. Large-flowered Tylophora. Br. n. 1. — Umbels nearly sessile, simple, of few flowers; their partial flasks smooth. Leaves heart-shaped, ovate, acute, downy as well as the branches. — Native of Port Jackson, New South Wales.

4. T. paniculata. Paniced Tylophora. Br. n. 4. — Panicles forked. Segments of the corolla ligulate upwards. Leaves ovate, pointed, nearly smooth; the lowermost somewhat heart-shaped. — Discovered in the neighbourhood of Port Jackson, by Mr. Ferdinand Bauer, the botanical companion of Mr. Brown, to whose exquisite pencil the duty of perpetuating the acquisitions of their hazardous expedition, undertaken at the national expense, was entrusted. Yet so little has the engagement to the public been fulfilled, that except a small but exquisite falciculus of plates, and the excellent but incomplete publications of Mr. Brown, all the discoveries of these naturalists have as yet remained fruitless; not, certainly, for want of their ability or inclination to complete what they have undertaken, but because, as we prefigure, the due injunctions, as well as the necessary aids, have been withheld.

TYLOS, in Ornithology, a name by which many authors have called the turtur ibis, or redwing.

TYLOTICA, medicines supposed to promote the formation of callus.

TYLSEN, in Geography, a town of Brandenberg, in the Old Mark, on the Dicime; 5 miles S.W. of Salzwedel.

TYLUS, in Ancient Geography, a town of the Peloponnesus, on the coast of the Gulf of Messenia, between the islands Tyrides and the town of Lencrata, according to Strabo; it is called Τύλος by Paulus, who places it between the port of Meza and Talama. — Also, an island of the Perisian gulf, at the distance of twenty-four hours' navigation from the mouth of the Tlepcompass, according to Arrian. — Also, Tylus minor, distant 10 miles in the same gulf from the greater Tylus; named Arados by Strabo, and Aratos by Ptolemy.

TYLWITH, in matters of Heraldry and Defers, is sometimes used for a tribe or family branching out of another, which the modern heralds more usually call the second or third house.

TYLYDAN, in Geography, a river on the S. coast of the island of Java, which runs into the sea, S. lat. 7° 38'. E. long. 108° 47'.

TYMARA, a town of Hindooftan, in Bahar; 25 miles E. of Chuta Nagpour.

TYMBALES, Fr. kettle-drums, instruments of percussion, consisting of two metaline globes covered with parchment; beaten with two drum-sticks, in the form of round hammers or mallets, from eight to nine inches long. The tone is short and dull. They are tuned 4th to each other. The smallest drum produces the key-note of the compositions in which they are employed, and the largest, the 4th below; as in the key of C the tones are these: —

There are braces, by which the pitch can be raised or lowered at pleasure. See Drum, and Kettle-Drum.

TYMBER of Skins. See Timber.

TYMBRA, in Ancient Geography, a town of Asia, in Pifidia.

TYMBRE, Fr. in Myfics, is a term used to express that quality of tone or sound which renders a voice or instrument rough or smooth, harsh or sweet, coarse or mellow in tone. Sweet-toned instruments seem always sweet, and harsh-toned too loud. A perfect voice or instrument would be that which united force with sweetness. The quality of tone generally determines our idea of its force. The voice of Mazzoli, at once extremely powerful and extremely sweet, was miraculous.

There are perhaps no instruments that can be at once loud and sweet, except those of the violin family, played with a bow; as the violin, tenor, and violoncello.

TYMENIUM, in Ancient Geography, a mountain of Asia, in the vicinity of Phrygia.

TYMES, a town of Africa, in Libya.

TYMIUM, a small town of Asia, in Phrygia.
TYMNISSUS, a town of Afia Minor, in Caria. 
TYMNUS, a town of Afia Minor, in Caria, which derived its name from the promontory called by Mela Tynnias.

TYMPAN, or TYPANUM, in Architecture, the area of a pediment, being the part which is in a level with the naked of the freeze. Or it is the space included between the three cornices of a triangular pediment, or the two cornices of a circular one.

Sometimes the tympan is cut out, and the part filled with an iron lattice, to give light; and sometimes it is enriched with sculpture, in bairo-releveo, as in the west front of St. Paul's, in the temple of Castor and Pollux at Naples, &c.

Tympan is also used for that part of a pedestal called the trunk or dye.

Tympan, among Joiners, is also applied to the pannels of doors.

Tympan of an Arch, is a triangular space or table in the corners or sides of an arch, usually hollowed and enriched, sometimes with branches of laurel, olive-tree, or oak; or with trophies, &c.; sometimes with flying figures, as Fame, &c. or sitting figures, as the cardinal virtues.

Tympan, in Anatomy, Mechanies, &c. See TYPANUM.

Tympan, among Printers, is a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See Printing-Press.

TYPANOA, τυμπανα, among the Athenians, a capital punishment, in which the criminal, being affixed to the pole, was beaten to death with cudgels. Potter, Archæol. Græc. lib. c. 25. tom. i. p. 134.

TYPANIA, in Ancient Geography, a town of the Peloponnesus, in the interior of the Elide. Ptolemy.

TYPANITES, in Medicine, from τυμπανος, tympanum, a drum, a flatulent distension of the belly, which, when flruck, emits a sound which has been compared to the noise produced by that instrument. It has been called, in English, the tympany, and swindy dropy.

The tympanes is a swelling of the abdomen, in which the integuments appear to be much ftreched by some diftending power within, and they are equally ftreched in every position of the body. The fwellimg does not very readily yield to any prejudice; and as far as it does, being extremely elatic, it very quickly recovers its former flate, when the prejudice is removed. Being flruck, it gives an obfene sound, somewhat like that of a drum, or other ftreched animal membrane. No fluctuation within is to be perceived; and the whole feels less weighty than might be expected from its bulk. The uneafnefs from the definition is partially relieved by the discharge of wind from the alimentary canal, either upward or downward.

These are the charaets, then, by which the tympanites, or flatulent fwellimg of the belly, may be diftinguished from the afiec, or droply of that cavity, and from phyfemia, or folid tumours, sometimes occurring there; and many expeiments shew that the tympanites always depends upon a preternatural collection of air fomewhere within the teguments of the abdomen. But the fituation which the air occupies in different instances is somewhat different; and this produces the different species of the disease which nofologists have defcribed.

One species, and indeed the moft common and cureable species, is that in which the collected air is confined within the cavity of the alimentary canal, and chiefly in that of the intestines. This species, therefore, has been named the tympanites intestinals. (See Sauvages Nofol. Method.

Clafs. x. (ppec. 1.) To this species, indeed, which is the moft frequent, the charaet above given especially belongs.

A second species is, when the air collected is not entirely confined to the cavity of the intestines, but is also prefent between their coats; and such is that which is named by Sauvages tympanites enterophysis (Sauv. ppec. 3.) This has certainly been a rare occurrence; and has probably occurred only in consequence of the tympanites intestinalis, by the air escaping from the cavity of the intestines into the interticles of the coats. It is, however, possible, that an erofion of the internal coat of the intestines may give occasion to the air, to conflantly prefent in their cavity, to escape into the interticles of their coats, though in the whole of their cavity there has been no previous accumulation.

A third species is, when the air is collected in the face of the peritoneum, or what is commonly called the cavity of the abdomen, that is, the space between the peritoneum and vifeera; and then the disease is named tympanites abdominalis. (Sauv. ppec. 2.) The existence of such a tympanites, without any tympanites intestinalis, has been disputed; and it certainly has been a rare occurrence; but from several defections, it is unquestionable that such a disease has sometimes truly occurred.

A fourth species of tympanites is, when tympanites intestinals and abdominalis are joined together, or take place at the fame time. With refpect to this, it is probable that the tympanites intestinalis is the primary disease; and the other only a confequence of the air escaping, by an erofion or rupture of the coats of the intestines, from the cavity of thefe, into that of the abdomen. It is indeed poifible, that in confequence of erofion or rupture, the air which is fo conftantly prefent in the intestinal canal, may escape from thence in fuch quantity into the cavity of the abdomen, as to give a tympanites abdominalis, whilfe there was no previous confiderable accumulation of air in the intestinal cavity itself; but we have no facts by which to afcertain this matter properly.

A fifth species has also been enumerated. It is when a tympanites abdominalis happens to be joined with the afiects, or droply of the belly; and fuch a disease therefore is named by Sauvages tympanites oftiehus. (Sauv. ppec. 4.) In moft cafes of tympanites, indeed, fome quantity of ferum has, upon defection, been found in the face of the peritoneum; but that is not enough to confitute the species now mentioned; and when the collection of ferum is more confiderable, it is commonly where, both from the caufes which have preceded, and likewise from the symptoms which attend, the afiects may be conftdered as the primary disease; and therefore that this combination does not exhibit a proper species of the tympanites.

As this laft is not a proper species, and as fome of the others are not only extremely rare, but even, when occurring, are neither primary nor to be easily diftinguished, nor, as confidered in themselves, admitting of any cure, it will be unneceffary to take any farther notice of them: we shall therefore configure ourselves, in what follows, to the confideration of the moft frequent cafe and almost the only object of practice, the tympanites intestinals.

With refpect to this, it does not appear that it arises in any peculiar temperament, or depends upon any predifposition, which can be diftinguished. It occurs in either sex, at every age, and frequently in young persons.

Various remote caufes of it have been alledged; but many of these have not commonly the effect of producing this disease; and although fome of them have been truly antecedents of it, we can in few instances discover the
manner in which they produce the diseaft, and therefore cannot certainly aferm them to have been caufe of it.

The phenomena of this diseaft, in its feveral ftages, are the following.

The tumour of the belly fometimes grows very quickly to a confiderable degree, and seldom in the flow manner the affifes commonly comes on. In fome cafes, however, the tympanites comes on gradually, and is introduced by an un-
usual fluctuation of the flomach and inftines, with frequent borborygm, and an uncommonly frequent expulfion of air upwards and downwards. This ftate is also frequently at-
tended with colic pains, efpecially felt about the nave, and
upon the fides towards the back; but generally, as the dif-
cafe advances, these pains becomes confiderably. As the dif-
cafe proceeds, there is a partly conflant defire to dif-
charge air, but it is accompanied with difficulty; and when obtained, although it give fome relief from the fene of dif-
feftion, this relief is commonly transient and of short dura-
tion. While the difcafe is coming on, fome inequality of
theft, and tenfion may be perceived in different parts of
the belly, but the dilution foon becomes equal over the
whole, and exhibits the phenomena mentioned in the cha-
acter. Upon the firft coming on of the difcafe, as well as
during its progres, the belly is bound, and the faces dif-
charged are commonly hard and dry. The urine, at the
beginning, is ufually very little changed in quantity or quaf-
ity from its natural ftate; but as the difcafe continues, it is
commonly changed in both respects, and at length fomet-
times a faringury, and even an ichuria, comes on. The
difcafe has feldom advanced far, before the appetite is much
impaired, and digestion ill performed; and the whole body,
except the belly, becomes confiderably enceafed. Toge-
ther with these phenomena, a thrill and uncafy fene of
heat at length come on, and a confiderable frequency of
pulfion occurs, which continues throughout the courfe of the
difcafe. When the tumour of the belly aries to a confider-
able bulk, the breathing becomes very difficult, with a fre-
dquent dry cough. With all thofe phenomena, the ftrength of
the patient declines; and the fecile phenomena daily in-
creafing, death at length enfues, fometimes probably in con-
fequence of a gangrene coming upon the inftines.

The tympanites is commonly of fome duration, and to be
reckoned a chronic difcafe. It is very feldom quickly fatal,
except where fuch an affeétion suddenly aries in fevers.
To this, Sauvages has properly given a different appellation,
of meridifmus; and it may perhaps always be con-
fered as a symptomatic affeétion, entirely dilifant from the
tympanites which we are now confidering.

The tympanites is generally a fatal difcafe, feldom ad-
mitting of cure: but we fhall mention what may be at-
tempered in this way, after having endeavoured to explain
the proximate caufe, which alone can lay the foundation of
what may be rationally attempted towards its cure.

To aferm the proximate caufe of tympanites is fome-
what difficult. It has been fuppofed, in many cafes, to be
merely an uncommon quantity of air prefent in the alimenta-
tary canal, owing to the extrication and detachment of a
greater quantity of air than ufual from the alimentary
matters taken in. Our vegetable alimenta probably always
undergo fome degree of fermentation; and in confequence,
a quantity of air is extricated and defhched from them in the
flomach and inftines; but it appears, that the mixture
of the animal fluids which our alimenta meet with in the
alimentary canal, prevents the fame quantity of air from
being defhched from them that would have been in their
fermentation without fuch mixture; and it is probable that
the fame mixture contributes also to the re-afbortion of
the air that had been before in fome meafure detached.
The extrication, therefore, of an ufual quantity of air
from the alimenta, may, in certain circumftances, be fuch,
perhaps, as to produce a tympanites; fo that this difcafe
may depend upon a fault of the digestive fluids, by which
they become unfit to prevent the too copious extrication of
air, and unfit alfo to occasion that re-afboration of air,
which in found perfonal commonly happens. An ufual
quantity of air in the alimentary canal, whether owing to
the nature of the alimenta taken in, or to the fault of the
digestive fluid, does certainly ftomes take place; and
may possibly have, and in fome meafure certainly has, a
flare in producing the tympanites, but cannot be fuppofed to produce the
tympanites, which often occurs when no previous diforder
had appeared in the fystem. Even in thofe cafes of tym-
panites which are attended at their beginning with flatulent
diforders in the whole of the alimentary canal, as we know
that a firm tone of the inftines both moderates the extrica-
tion of air, and contributes to its re-afboration or ready ex-
pulfion, fo the flatulent phenomena which happen to ap-
pear at the coming on of a tympanites, are probably referred to a
lofs of tone in the fecular fibref of the inftines, rather
than to any fault in the digestive fluids.

Thefe, and other confiderations, lead us to conclude, that
the chief part of the proximate caufe of tympanites, is a lofs
of tone in the fecular fibref of the inftines. But further,
as air of any kind accumulated in the cavity of the in-
ftines fhould, even by its own elaficity, find its way
either upwards or downwards, and fhould alfo, by the
affdence of inspiration, be entirely thrown out of the body;
fo when neither the re-afboration nor the expulfion takes
place, and the air is accumulated to al lofes of the al-
imentary canal, it is probable that the paffage of the air along
the courfe of the inftines is in fome places interrupted. This
interuption, however, can hardly be fuppofed to proceed
from any other caufe than fpasmodic conftrictions in certain
parts of the canal; and we may conclude, therefore, that
fuch conftrictions concur as part in the proximate caufe
of tympanites. Whether fuch fpasmodic conftrictions are to
be attributed to the remote caufe of the difcafe, or may be
confidered as the confequence of fome degree of atony firf
arising, cannot with certainty be determined.

Cure of Tympanites.—Having thus endeavored to af-
 certain the proximate caufe of tympanites, we proceed to
treat of its cure; which indeed has feldom fucceeded, and
almost never but in a recent cafe of the difcafe. It may be
proper, however, to flate what may be reafonably at-
tempered; what has commonly been attempted; and what
attempts have fometimes fucceeded in the cure of this
difcafe.

It must be a firft indication to evacuate the air accumu-
lated in the inftines: and for this purpofe, it is neceffary
that thofe conftrictions, which had efpecially occurred its
accumulation, and continue to interrupt its paffage along
the courfe of the inftines, fhould be removed. As thofe,
never, can hardly be removed but by exciting the perifaltic
motion in the adjoining portions of the inftines, purgatives
have been commonly employed; but it is at the fame
fime agreed, that the more gentle laxatives only ought to be em-
ploved, as the more draffic, in the overftretched and tenfe
flate of the inftines, are in danger of bringing on inflamation.
It is for this reafon, alfo, that glfyyers have been frequently
employed; and they are the more neceffary, as the feces
collected are generally found to be in a hard and dry flate.
Not only on account of this flate of the feces, but, farther,
when glfyters produce a confiderable evacuation of and
and thus knew that they have some effect in relaxing the spasm of the intestines, they ought to be repeated very frequently.

In order to take off the contractions of the intestines, and with some view also to the carminative effects of the medicines, various antispasmodics have been proposed, and commonly employed; but their effects are seldom considerable; and it is alleged that their heating and inflammatory powers have sometimes been hurtful. It is, however, always proper to join some of the milder kinds with both the purgatives and glyters that are employed; and it has been very properly advised to give always the chief of antispasmodics, that is, an opiate, after the operation of purgatives is finished.

In consideration of the overstretched and tense state of the intestines, and especially of the spasmodic contractions that prevail, fomentations and warm bathing have been proposed as a remedy; and are said to have been employed with advantage: but it has been remarked, that very warm baths have not been found so useful as tepid baths long continued.

Upon the supposition that this disease depends especially upon an atony of the alimentary canal, tonic remedies seem to be properly indicated. Accordingly, chalybeates and various bitters have been employed; and, if any tonic, the Peruvian bark might probably be useful. But as no tonic remedy is more powerful than cold applied to the surface of the body, and cold drink thrown into the stomach; so such a remedy has been thought of in this disease. Cold drink has been constantly prescribed, and cold bathing has been employed with advantage; and there have been several instances of the disease being suddenly and entirely cured by the repeated application of snow to the lower belly.

It is hardly necessary to remark, that, in the diet of typhomatous persons, all sorts of food disposed to become flatus in the stomach are to be avoided; and it is probable, that the mineral acids and neutral fats, as antizymes, may be useful.

In obitute and desperate cases of typanumites, the operation of the paracentesis (tapping) has been proposed; but it is a very hazardous remedy, and there is no satisfactory testimony of its having been practiced with success. It must be obvious, that this operation is a remedy suited especially, and almost exclusively, to the typanumites abdominalis; the existence of which, separately from the interna, is very doubtful, at least not easily ascertained, yet it is not very likely to be cured by this remedy: and how far the operation might be fatal in the typanumites interna, is not yet determined by any proper experience. There would be a danger, indeed, of converting the typanumites interna into the typanumites abdominalis, by allowing the air to escape through the puncture of the intestine into the face of the peritonaeum, and thus of converting a lees diseased into a greater, and, in fact, of producing irreparable mischief.

TYMPANO TRIBA, among the Ancients, a designation given to an effeminate person, who could do nothing but play on the tympanum.

TYMPANUM, in Anatomy. See EAR.

TYMPANUM, Diffages of. The cavity of the drum of the ear is sometimes affected with a puriform ichorous discharge, attended with a loss of hearing, proportionate to the degree of disorganization which this part of the ear has sustained. In general, on blowing the nose, air is expelled at the meatus auditorius externus: and when this is the case, it is evident that the discharge is connected with an injury, or disorganization of the membrana tympani. However, when the Eustachian tube is obstructed with mucus, or matter, or when it is rendered impervious, and permanently closed by inflammation, the membrana tympani may not be perfect, and yet, it is clear, no air can in this state be forced out of the external ear in the above manner. An examination with a blunt probe, or with the eye, while the rays of the sun fall into the passage, should therefore not be omitted. If the membrane have any aperture in it, the probe will pass into the cavity of the tympanum, and the surgeon feel that his instrument is in contact with the ossicle.

In this manner the affection may be discriminated from a herpetic ulceration of the meatus auditorius externus. The causes are various: in carcinatina maligna, the membrana tympani occasionally inflames, and floughs; all the ossicle are discharged, and, if the patient live, he continues quite deaf. An ear-ache, in other words, acute inflammation of the tympanum, is the most common occasion of suppuration in this cavity, to which, and the cells of the mastoid processes, a good deal of pus collects. At length, the membrana tympani ulcerates, and a large quantity of matter is discharged; but, as the secretion of pus still goes on, the discharge continues to ooze out of the external ear.

Instead of stimulating applications, inflammation of the tympanum demands the rigorous employment of antiphlogistic means. Unfortunately, it is a too common practice, in this case, to have recourse to acrid spiritual remedies. Above all things, the repeated application of leeches to the skin behind the external ear, and over the mastoid processes, should never be neglected. As soon as the inflammation ceases, the degree of deafness, occasioned by it, will also disappear. This, however, does not always happen.

When an abscess is situated in the cavity of the tympanum, Mr. Saunders seems to think, that the membrana tympani should not be allowed to burr by ulceration, but be opened by a small puncture. Sometimes the diseafe, of which we are treating, is more injurious in its attack: flight paroxysms of pain occur, and are relieved by flight discharges. The case goes on in this way, until, at last, a continual discharge of matter from the ear takes place. The disorder is destructive in its tendency to the faculty of hearing, and it rarely stops until it has so much disorganized the tympanum and its contents, as to occasion total deafness. Hence Mr. Saunders very properly defends the propriety of making attempts to arrest its progress,—attempts which are not free from danger; and he cenfures the foolish fear of interfering with the complaint, founded on the apprehension, that bad constitutional effects may originate from stopping the discharge.

If the case be neglected, the tympanum is very likely to become carious; before which change, the disease, says Mr. Saunders, is most commonly curable.

Mr. Saunders divides the complaint into three flages:

1. A simple puriform discharge. 2. A puriform discharge complicated with funguses and polyph. 3. A puriform discharge with caries of the tympanum. As the disease is a local one, direct applications to the parts affected are chiefly entitled to confidence. Blister and fecons may be advantageously employed in aid of topical applications. Mr. Saunders's practice, in these cases, consists in administering laxative medicines, and fomenting the ear while inflammatory symptoms last, and afterwards injecting a solution of zincum vitriolatum, or cerusca acetata.

In the second stage, when there are funguses, he removes or destroys them with forceps, afterwards touches their roots with the argentum nitram, or injects a solution of slum, zincum vitriolatum, or argentum nitram.

TYMPANUM, in Architecture. See TYPANUM.

TYMPANI, Chorda. See SYMPHONIA.

TYMPANUM, Tumus, in Medicine, is a kind of wood placed
placed round an axis, or cylindrical beam, on the top of which are two levers, or fixed Pfaves, for the more easy turning the axis about, in order to raise a weight required.

The tympanum is much the same with the peritrochium; but that the cylinder of the axis of the peritrochium is much shorter and less than the cylinder of the tympanum. See Axis in Peritrochium.

Tympanum of a machine is also used for a hollow wheel, in which one or more people, or rather animals, walk to turn it; such as that of some cranes, calenders, &c.

Tympanum, Lat. a drum, in Antiquity; but in modern Music, it is equivalent with tymbales, or a pair of kettle-drums; which see. See likewise Timpano, Ital. for a kettle-drum.

Tymphaei, in Ancient Geography, a people of Thessaly, towards the source of the Peneus. Strabo.

Tyna, a river of India, in the easterm part of the peninsula on this side of the Ganges, according to Ptolemy; marked by D'Anville to the N. of Malaparra.

Tyran, a small post-town of the county of Armagh, Ireland; 69 miles N. by W. from Dublin.

Tynacle, William, (named also Hitching) in Biography, a learned martyr to the Reformation, was born towards the latter part of the fifteenth century, on the borders of Wales, but the precise place of his nativity is not known. He received part of his education at Magdalen-Hall, Oxford, where he imbibed the doctrines of Luther, which caused his being dismissed from Wolley's new college of Christ-church, into which he had been admitted; so that he removed to Cambridge, where he took a degree. From hence he removed to Gloucestershire, to take the charge of Sir John Welch's children; and, during his residence here, he translated Erasmus's "Enchiridion Militis Christiani" into English, for the benefit of the family with which he resided, and he often preached in and about Bristol. By the company which visited Sir John, Tyndale was reproached as a heretic, and articles were preferred against him by the chancellor of the diocese, so that he was under a necessity of removing to London, where he preached at St. Dunstan's in the West. Deprived of being admitted one of bishop Tonstill's chaplains, he made application for that purpose, but was disappointed. In a retirement near London, he prepared a translation of the New Testament into English, which he accomplished, by wearied industry, in about half a year; but the times would not admit of its publication. The author therefore withdrew to the continent, and at length took up his abode at Antwerp; and here he completed his work, which was printed in 1526, 8vo., without a name. The number of copies was 1500, most of which were bought in England, and industriously circulated. The zealous papists were alarmed, and foreseeing the diffusion of error and heresy, obtained orders from Warham, archbishop of Canterbury, and Tonstill, bishop of London, that those who possessed any copies should deliver them up on pain of excommunication. Tonstill procured all that were unfold at Antwerp, and having purchased them, they were brought over and burnt at St. Paul's Crotch. This circumstance favoured Tyndale's design, who took occasion to prepare a more correct edition, which was printed in 1534; and cheaper editions increased the circulation. In order to discourage and restrain these measures for disseminating the Scriptures, Sir Thomas More ridiculed Tyndale's version in a dialogue in 1529, to which Tyndale replied: and the king, in a court of star-chamber in 1531, with the concurrence of the prelates, universities, and clergy, pronounced a severe condemnation of it, together with other heretical books. Tyndale, however, persevered with undaunted resolution, and engaged in a translation of the five books of Moses from the Hebrew. But in a voyage to Hamburg he was shipwrecked, and lost his books, papers and money. At Hamburg, where he at length arrived, he met with Miles Coverdale, and cooperating in their labour, they completed the Pentateuch, and printed it in 1530. Tyndale published a translation of the prophecy of Jonah, with a prologue, in 1534, and thus ended his labour on the Old Testament. At Antwerp he took up his residence in 1534, as a place of safety; but Henry VIII. and his council employed a person to betray him under the mask of friendship, and he was conveyed as a prisoner to Vilvorde, where he remained for a year and a half. At length, in 1536, he was brought to trial upon the emperor's decree at Augsburg; and here he was condemned, and strangled at the stake; and his body was reduced to ashes. He expired with uttering this prayer, "Lord, open the king of England's eyes!" It is needful to make any reflections on the conduct of such favage percutors, who thus treated a man of irreproachable manna, and who was pronounced, by the emperor's procurator, who affiliated in his condemnation, "Homo doctus, plus, et bonus," for no other crime besides that of enabling Christians to peruse a book which is the only authoritative directory of their faith and practice. Tyndale's other works were introductions to, and comments upon, parts of Scripture. Biog. Brit.

Tyndarides, in Mythology, a name given by the poets to Caltor and Pollux, the sons of Jupiter and Leda. Though, according to the fable, Pollux and Helena proceeded from the egg which Leda had conceived by Jupiter, and were therefore immortal; whereas, out of another egg, which the conceived by Tyndarus, her husband, came Caltor and Clytemnestra, who were mortal. See Castor and Pollux.

Tyndaris, in Ancient Geography, Pandari, a town of Asia, in the Colchide, on the right bank of the Phasis, E.N.E. of Circeum, and S.W. of Cyta (Cutatis.) Pliny.—Alfo, a town of Sicily, towards the S.W., which was a Roman colony. It is called by Ptolemy Tyndarium.

Tyndis, Panda, a port of India, upon the coast of the country denomined Lymyrca, according to the Periplus of the Erythrean sea.

Tyndus, Tanaon, a river of India, in the peninsula on this side of the Ganges. Ptolemy.

Tyne, in Geography, a river of Scotland, which rises a few miles S. of Dalkeith, crosses the county of Haddington, and runs into the German sea, N. lat. 56° 2'. W. long. 2° 38'.

Tyne. See Tine.

Tyne-mouth, a township in the east division of Castle-Ward, in the county of Northumberland, England is situated on the banks of the river Tyne, 9 miles E.N.E. from Newcastle, and 286 miles N. by W. from London. It is a place of remote antiquity; and recent discoveries have proved that the Romans had buildings here. It is chiefly noted for its ancient monastery, which is reckoned to be one of those founded by Oswulf, the first Christian king of Northumberland. Great local facility was soon attributed to it, and several kings and other illustrious persons were buried here. St. Herebalb, the companion of St. John of Beverley, was abbot here at the beginning of the eighth century; but before the end of it, the monastery was plundered by the Danes, as it was again in the next century by the forces under Hunguar and Hubba, and a third time in the reign of King Athelstan. The old church seems to have lain desolate for a century, till a short time before the Norman conquest, when Tolfi, earl of Northumberland, rebuilt and
and endowed it. On the banishment of Tolotti, the Conqueror gave his possessions to Robert de Mowbray, who then became earl; he refounded Tynemouth priory, and filled it with Black monks from St. Alban's, to which abbey the priory was subordinate. In his conspiracy against William Rufus, he converted the place into a fortress, which, after a siege of two months, was taken by storm. The priory progressively increased in consequence. In 1244, the prior mediated a peace between England and Scotland; and soon after obtained a charter from Henry III. to hold a market in his manor of Bacterial. He also claimed a market for Tynemouth; but in a suit on that account, judgment was given against him. Many privileges and immunities were, however, obtained for the inhabitants. At the surrender of the priory, in 1539, its possessions were very large, having twenty-seven villages with their royalties, besides the improvisations of many churches; its annual income being estimated at 70s. 12d. The chief remains are those of the church, at the east end of which is a neat little chapel or oratory. Till 1569 the church was parochial, but being decayed and damaged during the civil war, another was erected, and completed in 1668; but the old cemetery is still much used in preference to the new one. The castle, erected by earl Mowbray, appears to have been a place of great strength. It was garrisoned in the reign of queen Elizabeth; and again in that of Charles I., when it was besieged and taken by the parliamentary forces. Little remains of this ancient fortress except a strong gateway, the approach to which has been recently flanked with bastions. The village of Tynemouth is much frequented in the bathing season, and commodious and warm and cold baths have been erected. Here are some considerate fall-works; and it is estimated that 700,000 chaldivons of coal are annually sent hence to London. In the population return of the year 1811, the number of houses in this township is stated to be 950; and of inhabitants, 5834.—Beauties of England, vol. xii. Northumberland, by the Rev. R. Hodgson.

TYNIDRUM, or Tsuurodomun Colonia, Hydraclub, in Ancient Geography, a town of Africa, mentioned by Ptolemy, and placed by him two degrees W. of Sicca Veneria.

TYNIEZC, or Tynez, in Geography, a town of Austrian Poland, on the Vitula; 4 miles S.W. of Cracow.

TYNNA, in Ancient Geography, a town of Afia, in the Lefier Armenia, and in the prefecture named Catziona. Ptol.—Allo, a river of India, on this side of the Ganges, the mouth of which was in the country of the Avari. Ptolemy.

TYNSBOROUGH, in Geography, a town of Maffachusetts, in the county of Middlesex, containing 704 inhabitants; 31 miles N. of Boston.

TYONISTA, a river of Pennsylvania, which runs into the Alleghany, N. lat. 41° 29'. W. long. 78° 30'.

TYORA, in Ancient Geography, commenced "Matienus," a town of the Aborigines, on the coast of Latium; distinguished by a very ancient oracle of Mars.

TYPA, in Geography, a harbour on the coast of China, at the entrance of the river of Canton, formed by several islands. The anchoring place is N. lat. 22° 9'. E. long. 113° 48'.

TYPEA MONE, in Ancient Geography, a small mountain of Triphylia, near the banks of the river Alpheus. It was a law of the Eleusins, that any female who was surprised in attendance at the Olympic games, should be precipitated from this mountain, the reason of which law is said to have been, that the Athletes were naked in their exercises.

TyTE, Tyte, formed from nova, form, figure, a copy, image or resemblance, of some model.

The term type is left in use than its compounds prototype and archetype, which are the originals that are made without models.

Type is also a scholastic term, much used among divines, signifying a symbol, sign, or figure, of something to come. In this sense the word is commonly used with relation to antitype, antitypion, which is the thing itself, of which the other is a type or figure.

Thus Abraham's sacrifice, the paschal lamb, &c. were types or figures of our redemption; and the brazen serpent was a type of the crofs, &c.

Types are not mere conformities, or analogies, which the nature of things holds forth between them; nor arbitrary images arising merely from the casual resemblance of things; but there is farther required a particular institution of God to make a type, and a particular declaration of his that it is so.

Gale divides types into historial and prophetical. The first are those used by the ancient prophets in their agitations and visions: the second, those in which things done, or ceremonies instituted in the Old Testament, prefigure Christ, or things relating to him in the New Testament. Or, they are things which happened and were done in ancient time, and are recorded in the Old Testament, and which are found afterwards to describe or represent something which befell our Lord, and which relates to him and his gospel. E. gr. Under the law, a lamb was offered for a sin-offering, and thus an atonement was made for transgressions. John the Baptist calls Christ "the lamb of God that taketh away the sins of the world," and St. Peter tells Christians that they are redeemed "by the blood of Christ, as of a lamb." Hence we infer and conclude that the lamb was a type of Christ; and upon considering it, we find that it has all that can be required to constitute a type; for it is in many respects a very just and lively representation of Christ. The lamb died for no offence of his own, but for the sins of others; so did Christ: the lamb could not commit sin by his nature, nor Christ by his perfection: the lamb was without bodily spot or blemish: Christ was holy and undefiled: a lamb is meek and patient: such was the afflicted and much injured Son of God.

These types are useful to persons who have already received Christianity upon other and stronger evidence, as they shew the beautiful harmony and correspondence between the Old and New Testament; but they seem not proper proofs to satisfy and convince doubters, who will lay perhaps, with the schoolmen, "theologia symbolorum non efi argumentativa."

Unless we have the authority of the Scriptures of the New Testament for it, we cannot conclude with certainty that this or that person, or this or that thing mentioned in the Old Testament is a type of Christ, on account of the resemblance which we may perceive between them: but we may admit it as probable.

The ancient fathers, as well as the modern critics, have been greatly divided about the nature and use of the types and typical representations in the Old Testament; and it is this makes one of the great difficulties in understanding the ancient prophecies, and in reconciling the New and Old Testament together.

There is no denying but that there were some types which the divine wisdom instituted to be the shadows and figures of things to come; and yet people run into an excess that way: some looking for types in every thing, like Origen, who deciphered myriads in the very cauldrons of the tabernacle. A prudent man should be contented with the more sensible and obvious ones, nor propose any without
without proving them as much as possible, and shewing that
they were really intended for types, in order to justify the
fidelity of the reasoning of the apostles, who argued from
them.

An author, in reference to this subject, maintains, that
not the fathers only, but St. Paul himself, was of the op-
inion, "that Christianity was all contained in the Old Te-
ftament, and was implied in the Jewish history and law; both
which are to be reputed types and shadows of Christiannity."
In order to which, he quotes Hebrews, vii. 5. x. 1. and
Colof. ii. 16. 17. He adds, "that the ritual laws of
Mofes, being in their own nature no other than types and
shadows of future good things, are to be considered as hav-
ing the effect of prophecies." This is likewise the sense of
Mr. Whilton, and others; but the same author even quotes
our Saviour speaking in behalf of this typical reasoning in
that passage, Matth. xi. 13. where he affirms that, "the
law prophesies; and that he came to fulfil the law as well
as the gospel." (Matth. v. 17. Diff. of the Grounds, &c.)
An ingenious divine takes this occasion to observe, that
had the ancients, with the modern retainers to the typical
way, expressly designed to have exposed Christiannity, they
could not have done it more effectually than by thus making
everything types and prophecies.

Not that he denies the reality of such things as types. It
is manifest there were many under the Old Testament: such
were Zechariah's flames, beauty, and bands, ch. xi. 7. ro.
14; such was Hophia's adulterous wife, chap. i. 23; and such
were his children, ver. 4. 6. The prophets designed by
these to prefigure future events; but in these instances the
reader is at once, by the declaration of the prophet, made
to understand as much, and not left to his own conjectures
about them after the events are over.

In effect, all that is urged from Scripture for the typical
or allegorical interpretations of the Jewish law, history,
ceremonies, &c. it is affected, may be set aside, without any
violence to the Sacred Text, which may be explained on
more natural and intelligible principles, and more consis-
tently with grammar.

The word τύπος, we have observed, literally denotes no
more than a copy or impreffion of any thing; and accord-
ingly, in our translation, we find it sometimes rendered by
print, sometimes by figure, sometimes by fcripture, and some-
times by form.

Hence also the word is figuratively applied to denote a
moral pattern; in which sense it signifies no more than ex-
ample and similitude.

Again, the word ἑκτύπος, antitype, in Scripture, signifies
anything formed according to a model or pattern; and thus,
in the Epifile to the Hebrews, the tabernacle, and
holy of holies, being made according to the pattern shewn
to Mofes, are said to be antitypes, or figures, of the true
holy places. In the like sense, St. Peter, speaking of the
flood and the ark, by which eight perfons were faved, calls
baptifm an antitype to them; by which he expreffes no more
than a similitude of circumftances.

The other words used in Scripture to imply a future
event, prefigured by fome foregoing act, are,—ἐκτύπωμι, rendered by imitation and example; and ἱμάριστο, shadow.

Such being the import of all the terms used in the New
Teftament writers, seeming to imply any prefiguration of
future events under the Gospel, it is observed,

1. That to argue from types, is only to argue from ex-
amples or similitudes; and, consequently. that all inferences
drawn from fuch reafonings are no farther conclufive than
reafonings from similitudes are. The intent of similitudes is
only to help to convey some ideas more clearly or strongly;

so that to deduce confequences from a simile, or infer any
thing from other parts of the simile, than what are plainly
similar, is absurd.

The fame author also alleges, 2. That it cannot be
proved, that the ceremonies of the Mofic law were ever
designed to prefigure any future events in the state of the
Mefiah's kingdom. No fuch declared prefigurations are
mentioned in the writings of the Old Testament, whatever
notions prevailed among the writers who immediately fol-
lowed. It is granted, that the apostles argued from the
rites in the Mofic institution; but this (he fays) appears to
have only been by way of illustration and analogy.

There is certainly a general likenefs in all the difpen-
sations of Providence; an analogy of things in the natural
as well as the moral world, from which it is easy arguing by
way of parity, and it is very jufl and ufual fo to do; but that
one of these difpenfations was therefore given to prefigny
another that was future, can never be proved, unless it be
expressly declared.

It is in the fame way of fimilitude (he maintains) we are to
underland St. Paul, where he fays, "that Chrift our fad-
over is facrificed for us." And thus we are to understand
John the Baptist, when he calls our Saviour the "Lamb
of God." There was this fimilitude of circumstance, that
Chrift was slain on the fame day with the paflch lamb;
that he died about the fame time of the day when the proles
began their hillel; that not a bone of the one or the other
was broken. Add, that as the paflch lamb was without
blemith, fo was Chrift without fin. From thefe, and other
circumftances, the apostle applied the term πασχαλιον to
Chrift.

Thus, also, we are to account for what St. Paul calls the
baptifm of the children of Ifrael in the cloud, and in the
fea; and for the comparifon betwixt the high-priest entering
the holy place every year, and Chrift entering into heaven.

Sykes's Exfay on the Truth of the Christian religion, 1725.

Τύπος, τύπος, is also a name given to an edict of the em-
peror Conftans II. publifhed in 648, to impose a general
filine both on the orthodox and the Monothelites.

It had the name of type, as being a kind of formulary of
faith; or rather a form on which men were to regulate their
conduct.

The type owed its original to Paul, patriarch of Con-
ftantinople, who perfaudied that emperor to take away the
efthefs, compiled and hung up in all the public places by
Heraclefs, as occupying great complaints from the ortho-
dox, by its favouring the Monothelites; and to publifh an
edict to impose silence on both parties.

But fuch kinds of pacifications are held inexcufable in
matters of religion; accordingly pope Theodore fon
procured the patriarch Paul to be depofed; the type was ex-
mained in the council of Rome, conffituting of a hundred
and five bishops, in 649, and condemned; and an anathema
was pronounced againft all fuch as admitted either the impious
efthefs or τύπος.

Τύπος, TYPUS, is also ufed to denote the order obferved
in the intimation and reemifion of fevers, pulfes, &c.

Τύπος, among Letter-founders and Printers, denotes the
fame with letter. See FOUNDERY.

TYPHA, in Botany, Cat's-tail, or Reed-mace, τύπος of
the ancient Greeks, from τύπος, a beg or sarfes, of which fpecies
the plants of this genus are among the moft confficious in-
habitants. They are often vulgarly mitkaken for the Bull-
rub, a very different plant. (See Sirchius, fef. 2.)—
Brown
Towards the base of each is a dense, or channelled, on the upper. There is always a naked space between the male and female catkin. The roughness of the male flower is rather chaffy than hairy, and seems to take place of the perianth. The fruit-bearing catkin sometimes splits longitudinally, in growing, into four dismembered portions.

The original Linnean names have been retained in Fl. Brit. and by the English botanists in preference to Curtis's major and minor, which latter might have led only to confusion.

3. T. minor. Dwarf Catkin-tails, or Reed-mace. Fl. Brit. n. 3. Engl. Bot. t. 1457. Willd. n. 2. Ait. n. 2. "Bauh. Hift. v. 2. 540. Lob. 1c. 81. (T. angustifolia s; Linn. Sp. Pl. 1378. Hudf. 400. T. minima; Willd. n. 4. T. palustris minima, duplici clav; Morif. fect. s. t. 13. f. 3. )—Leaves linear; convex at the back. Catkins a little distant; the male leafy; female short and turgid. Native of marshy, rather sandy, places, in England, Switzerland, and Germany, flowering in July or August. The root is perennial and creeping, and the habit of the plant like the two foregoing species, but its size much smaller than either, the stem being only twelve or eighteen inches high, and very slender, sheathed with broad scales about half its length, which have been mistaken for leaves. The real leaves springing, as described by the English Botanists, from a different parcel of similar scales, and are all the same, scarcely a line in breadth, slightly channelled, convex at the back. Catkins each about an inch long, a little distant from each other; the male with a leafy scale or two at its base, middle, or fummit; the female somewhat elliptical, timid, often divided. Anthers mostly solitary. Flowers not much interfered with hairs or chaffy scales. There can be no doubt, from Wildenow's description, of his T. minima being the same plant as minor, of which latter he was not conscious of having seen a specimen.—T. minor was found on Hounslow Heath in the time of Dillenius. We have not heard of it from any recent collector.

The second of Jussieu's classes is formed of monocotyledonous plants, whose flowers are infertile below the germs. Their calyx is either of one or more leaves, or wanting. Corolla (in Jussieu's opinion) none. Stamens inferior, mostly definite in number. Germin superior, simple; style either one or more, or wanting; stigma simple or divided. Seeds solitary, naked or covered; or the fruit is of one cell, with one or many seeds. Leaves mostly alternate and fleathing. Flowers sometimes distinct in sex, by the failure of one or other of their organs of impregnation.—The orders are four; Aroides, Typhes, Cyperoides, and Gramineae; for the two last, see CALAMARIAE and GRAMINA. The Aroides consist of Ambrosia, Zofe, Arum, Cala, Dracouon, Pothos, Huottymnia, Orontium, and Acon. The Typhes are thus characterized. Flowers monocious; the male aggregate, triandrous, with a three-leaved calyx; the female aggregate, with a three-leaved (rather, we would say, many-leaved) calyx; germin superior; style simple; seed solitary. Leaves all alternate and fleathing. Plants herbaceous and aquatic.

Mr. R. Brown makes the Typha of Jussieu but a section of his Aroides. He observes that their seeds are pendulous; those of Sparganium each in a dry drupa, those of Typha in that kind of membranous close capsula termed by Garttner uriculae.
TYPHUS, a name used by some authors for colt's-foot.

TYPHIUM, in Ancient Geography, a mountain of Greece, in Beroia.

TYPHLE, or TYPHLINE, a name by which some authors have called the fish more usually known by the name of the 

TYPHILUS, in Zoology, the name by which the Greeks, and from some other authors, have called the eel, or flow-worm.

TYPHLITUS, TYPHOMANIA, from τυφλος, blind; blindness.

TYPHODES, in Medicine. See Typhus.

TYPHONIS, TYPHCEUS, TYPHUS, TYPHOMANIA, probably from τυφλος, smoke, and μανία, frenzy; but the propriety of which is not very obvious, a term used by the older writers in medicine to denote a state of diseased in which lethargy was combined with delirium, or, as some have rated, an apparent sopor with actual watchful-ness: whence the appellation has been derived synonymous with coma vigil. A more accurate pathology has discriminated these vague distinctions; for every degree of morbid from melancholy, from lethargy up to complete apoplexy, appears to be the same in kind, differing only in degree.

See APOLLEXY, COMA, and LETHARGY.

TYPHON, or Typhæus, in Mythology, the name of one of the rebel giants.

The fable of Typhon is one of the most mysterious among the ancient mythologists. The Greeks and Latins, depending upon traditions received from the Egyptians, describe him as a horrid monster, produced, as they say, from the Earth by the jealous Juno, in order to avenge herself on Latona, her rival. Heidet says, that this giant was the son of Tartarus and Terra. Manilus expresses himself to this purpose:—

"Merito Typhonis habentur
Horrende fedes, quem Tellus seva profudit,
Cum bellum Carlo peperit."

Apollodorus makes Typhon the most terrible of all monsters; describing him as having a hundred heads, and as issuing from his hundred mouths devouring flames, and howlings so dreadful, that he equally terrified gods and men. His body, whose upper part was covered with feathers, and the extremity entwined with serpents, was so vast, that he touched the skies with his head. His wife, says this author, was Echidna, and his offspring were the Gorgon, Geryon, Cerberus, the Hydra of Lerna, the Sphinx, and the Eagle which preyed upon the unfortunate Prometheus; in a word, all the monsters that were hatched in the country of fables. Hyginus adds, that Typhon no sooner sprung from the earth, than he resolved to declare war against the gods, and to revenge the overthrow of the giants. A contest took place between Typhon and Jupiter, which, after various dreadful conflicts, terminated in the defeat of Typhon, who, being pursued by Jupiter and affaided with thunderbolts, was at last driven into Sicily, and there buried under mount Etna. The conjectures of modern authors in their attempts for explaining this fable have been very various. Some, among whom is G. Voilès, are of opinion that Typhon was the same with Os, king of Babylon. Bochart supposes that he was the same with Enceladus. Some authors think that Typhon was king of Sicily, and others that he was the same as Eliau. Heurt apprehends that Typhon was the legistrator of the Hebrews, becoming extremely odious to the Egyptians by the destruction of their first-born. Banier supposes, that Typhon and his brother Ofiris were much more ancient than Moses; and that the idolatrous worship of the oxen Apis and Minevis, consecrated to Ofiris, was spread through Egypt before the Israelites entered there, since it was upon this model, according to Selden, that Aaron made the golden calf which the Jews worshipped in the wilderness. A dispute arose between Typhon and Ofiris, and he was drowned, as it is said, on the authority of Herodotus, in the marshes of the lake Serbonis, or killed in a battle fought with his nephew Orus, whence the Egyptian priests made the people believe, that the gods interred themselves in avenging Ofiris, by destroying his persecutor with a thunder-bolt. Thus, however, perished the cruel tyrant of Egypt, and the kingdom was left to young Orus, under the regency of his mother Isis. For further particulars we refer to Banier's Mythology, vol. i.

TYPHUS, or Typhus, in Physics. See WHIRLWIND.

TYPHONIS INSULA, in Ancient Geography, an island of the Mediterranean sea, upon the coast of the Troade.

TYPHUS, or Typhæus, in Mythology, a term used by Hippocrates to denote a fever of an inflammatory character, probably derived from τυφλος, I inflame. The disease, however, not having been very distinctly described by that writer, other authors have applied the term to fevers of a nervous character, and it is now received as the appellation of ordinary low fever, and flanks in opposition to inflammatory fever. In short, by the word typhus, we now understand the common contagious fever of this and other northern climates, which has received various appellations, according to the situations in which it has prevailed, or to some of its symptoms, or to the degree of its severity; such as hospital, gal, and ship fever; petechial, spotted, or purple fever; putrid, malignant, infectious fever; continued fever, &c. This common fever, or typhus, differs essentially from the eruptive fevers, small-pox, measles, chicken-pox, and scarlet fever, which affect any individual but once during life; it differs from the plague of the East, which is accompanied with huboes, and from the yellow fever, the bilious remittent fever of hot climates; and from the remittent and intermittent fevers, the effect of marsh effluvia, in more northern latitudes; but, under all the circumstances, is the same, and described exactly. It appears to be of the fame nature, and is usually understood by physicians in Europe, when they speak of fever simply. As we have entered at great length into the nature of this disease, and the doctrines of pathologists respecting it, under its proper head, it would be superfluous to enter more largely into the subject here. See FEVER.

TYPIC FEVERS, an appellation given by medical writers to those fevers which are regular in their attacks, and in their general period: they are thus called by way of distinction from the erratic, which observe no regular type, or determinate appearance.

TYPOGRAPHY, formed from τυπος, and γραφειν, writing, the art of printing.

TYPOLITEIS, or TYPOLITHUS, formed of τυπος, type, and λίθος, stone, in Natural History, names given to stones or fossils, on which are imprinted the figures of various animals and vegetables. See STONES, ADVENTITIOUS FOSSILS, &c.

TYR, in the Ethiopian Calendar, the name of the fifth month of the Ethiopian year. It commences on the 25th of December of the Julian year.

Tyr, in Mythology, a name given to a warrior deity, the protector of champions and brave men, invoked by the ancient northern nations.

The third day of the week was consecrated to Tyr, from whom, it is said, the name given to it in most of the northern languages is derived: it is called in Dan. Tydflag, or Tisdag; in Sued. Tisdag; in English, Tuesday; in Low Dutch, Dingdag; and in Latin, Dies Martis: whence it is inferred, that Tyr answered to Mars. The
TYR

The Germans, in High Dutch, call this day Erts-bag, from the word birti or bare, a warrior, which comes to the same thing.

Tyr must be distinguished from another deity called Thor Mallet's North. Ant. vol. i. p. 99.

TYRA, in Ancient Geography, a town of European Sar-matia, upon the banks of the river Thyras; sometimes called Ophiuia.

TYRA, in Geography, a river of Germany, which runs into the Kelm, one mile W. of Kelbra, in the county of Schwartzburg.

TYRAMBE, in Ancient Geography, a town of Afian Sar-matia, 660 fladis from the river Khombites, according to Strabo; but Ptolemy places it between Azabites Mitra and the mouth of the river Atticurus.

TYRAN, or Tyron, in Geography, a small island in the Red sea. N. lat. 27° 40'. E. long. 34° 29'.

TYRANNICIDE, formed of tyrannus and casco, I kill, denotes the act of killing a tyrant.

TYRANNIO, in Biography, a Greek grammarian, was a native of Amià, in Pontus, and a disciple of Dionylus of Thrace at Rhodes. Upon the conquest of the kingdom of Mithridates by Lucullus in the year B. C. 70, Tyrannio became a captive, but was liberated by Murena, and taken to Rome, where he opened a school, in which he gave instruction to the son and nephew of Cicero, and also to Strabo. In this situation he acquired considerable wealth, and accumulated a library of more than 30,000 volumes. Among other valuable works which he possessed, he preferred the writings of Aritotle and Theophratus, which he obtained from the librarian of Sylla, and which he afterwards imparted to Asdrubius of Rhodes. Tyrannio lived to an advanced age; but none of his works are extant.

Bayle.

TYRANNUS, in Ornithology, a name given by some to the lanius, or butcher-bird, a species of hawk not larger than a thrush, but a very fierce and fatal enemy to the small birds. See Lanius.

TYRANNY, in Political Government, is the exercise of power beyond right, to which nobody can have a right; and thus it is distinguished from Ufurfation, (which fee,) or the exercise of power which another hath a right to: and it is the use of power which any one possesses, not for the good of those who are subject to it, but for his own private separate advantage; when the governor, however, intituled, makes not the law, but his will the rule; and his command and actions are not directed to the preservation of the property of his people, but the satisfaction of his own ambition, revenge, covetousness, or any other irregular passion.

It is a mistake to think this fault peculiar to monarchies; other forms of government are liable to it as well as that. For wherever the power that is put in any hands for the government of the people, and the preservation of their property, is applied to other ends, and made use of to improve, harass, or seduce them to the arbitrary irregular commands of those that have it, there it becomes tyranny, whether those who thus use it are one or many.

Accordingly we read of the thirty tyrants at Athens, as well as one at Syracuse; and the intolerable dominion of the deccmvi at Rome was nothing better. Every wanton and capricious restraint of the will of the subject, whether practised by a monarch, a nobility, or popular assembly, is a degree of tyranny.

Whenever the constitution of a state vests in any man, or body of men, a power of destroying at pleasure, without the direction of laws, the lives or members of the subject, or of alienating their property, or of depriving them of their liberty at pleasure, such constitution is tyrannical. In a word, wherever law ends, tyranny begins, if the law be transgressed to another's harm. And whoever in authority exceeds the power given him by the law, and makes use of the force he has under his command, to compacts that upon the subject which the law allows not, ceases in that to be a magistrate, and, acting without authority, may be opposed as any other man, who by force invades the right of another. The end of government, whatever be its name or nature, is the good of mankind; and upon this principle, whoever uses force without right, as every one does in society who does it without law, puts himself into a state of war with those against whom he uses it; and in that state all former ties are cancelled, all other rights cease, and every one has a right to defend himself, and to refit the aggressor.

If it be asked who shall be judge; whether the prince or legislative act contrary to their trust? The answer is obvious, the people shall be judge; for who shall be judge whether the trustee or deputy acts well, and according to the trust repdced in him, but he who deputes him, and multi, by having deputed him, has filled a power to discard him when he fails in his trust? If this be reaonsable in particular cases of private men, why should it be otherwise in that of the greatest moment, where the welfare of millions is concerned; and also where the evil, if not prevented, is greater, and the redrefs very difficult, dear, and dangerous? Locke, of Civil Government, ch. xviii. and xix. in his Works, vol. ii. p. 214, &c.

TYRANT, Tyrannus, among the Ancients, denoted simply a king or monarch.

But the ill use several perfons invested with that character made of it, has altered the import of the word, and tyrant now carries with it the idea of an unjust and cruel prince, who invades the people's liberty, and rules in a more defpotic manner than the laws of nature, or the country, do allow.

The term tyrant, we are told, became odious among the Greeks, those zealous lovers of liberty, almost as soon as introduced; but Donatus affures us, it was never taken so among the Romans till the latter ages of that empire.

The motto of a tyrant in Oderim dum metuunt. Rowland contends, that this word, as well as the correspondent Greek and Latin, is derived from tir, Welh and Efe, land, and rhanner, Welsh, to flare; q. d. tirbannon, a sharer or divider of land among his vassals. Johnfon.

TYRANTS, Thirty, an appellation under which the thirty perfons, establiished by the Lacedaemonians in Athens, in order to enlave and keep it in slavery, are denominated. Thrafbulus formed the generous design of driving them from Athens, and succeeded; upon which event Cornelius Nepos has remarked, that many have desired, and few had the happiness to rescue their country from a single tyrant: but Thrafbulus delivered his from thirty.

One of the means which these tyrants used for carrying on their scheme of enslaving the Athenians, was the ordering of the suffrages of the Areopagites to be public, that they might manage them as they pleased. See Montefquieu's Spirit of Laws, vol. i. p. 17.

TYRAS, in Ancient Geography. See Dixistr.

TYRAWLEY's Point, in Geography, the south-west extremity of Trevannon's island, in the South Pacific ocean. S. lat. 16° 48'. E. long. 163° 41'.

TYRBE, a Festival in Antiquity, a festival celebrated by the ancients in honour of Bacchus.

TYRE, in Ancient Geography, a city of Phoenicia, distant 23 miles from Sidon, its rival, according to the Itinerary of Antoninus. (See Sidon.) This city was anciently denominated
TYRE.

Ith and under but as and

Thefe other old mole, grapher, Pliny's in

Oftus, Whetther directly thrown at

Tyrus, including Pale-tyrus, was 19,000 paces in circum-

ference, whence it is plain, that Tyre on the ifland, and

Old Tyre on the main, were considered as but one city, after

the ifthmus was thrown up between them; and poihly they

might have had buildings contiguous to each other. If

Pliny's numbers are right, the old city must have been by

much the moft extensive part of the whole, and especially

as the place appears at this day. According to Pliny, the

ifland was but 700 paces from the continent; whereas Strabo

fays that it was 30 ifadia, or somewhat more than three of

our miles from Pale-tyrus; and according to the fame ge-

ograph, Tyre was wholly an ifland, like Aradus, excepting

the artificial ifthmus, which formed it into a peninsula. The

city by itfelf, according to the iftement of Pliny, meafured

only twenty-two farilongs, or not quite three of our miles, and

this is too great an allowance, if we may rely on our

modern accounts; which reprefe Tyre itfelf as a ifmall city

in extent, though it covered the whole ifland; and the fea-

ifaces of the space on which it iflood, induced the inhabitants

to rafe their buildings fo high, which plan they would have

otherwise avoided, from fear of earthquakes, that threatened

them with deftuction. At preuent the ifland appears to

have been, in its natural ifate, of a circular form, hardly con-

taining forty acres of ground; and the foundations of the

wall which surrounded it are still to be feen at the utmost

margin of the land. If it be true then, that the whole cir-

cuit of the old and new Tyre amounted to 19,000 paces, or

19 Roman miles, and that they were dilant from each other

but 33 ifadia, or 3 of the fame miles, it is evident that the

old city flood upon a much greater space of ground than the

new. A coniderable part of the ifland was, what we call

made ground. The buildings were in general spacious and

magnificent; and above the refi appeared the temples

built by Hiram to Jupiter, Hercules, and Aifarte. The

walls of Tyre were 150 feet high, proportionally broad, and

firmly built of large blocks of ifone, bound together with

white peftler. For its preuent reduced and ruinous ifate,

see Sur.

Heredotus afcribes to Tyre fitated on the ifland a very

ancient epocha; and its priets, according to his account,

reprefe that their temple, which was of greater anti-
quity than the city, fublifted about 450 years before the

Christian era. Jofephus refers the foundation of this city
to 1255 years B.C., whilst the ifraelites were under the
government of judges. But these dates cannot be applied

to infular Tyre, which was more modern than that of con-
tinental Tyre, which is laid to have been built and known

before the ifraelites took posfession of Cannan. (See Jof.

xix. 25.) The Sidonians, with a view of extending their com-

merce, fent out a colony to ancient Tyre, which contributed

very much to its augmentation; and hence it became pow-

erful, eclipsed the metropolis, and became itfelf the metro-

polis of feveral cities, which it furnished with colonies. The

Tyrians were not known in the time of the Trojan war,

according to Strabo (lib. xxi.) and Homer, who often speaks

of the Phcenicians, mentions only the Sidonians, under

which general appellation the Tyrians were probably com-

preended.

Jofephus and Theophilus Antiochenus begin the fucce-

fion of kings of Tyre with Abibal, upon the authority of

Menander the Ephefian, and Dius a Phcenian, authors of

credit. Abibal was contemporary with David, and his reign

is referred to 1056 B.C. He was fucceeded by his fon,

Hiram (1046 B.C.), who maintained an intimate friend-

ship with David and Solomon: under this prince the king-

dom of Tyre was very proflorous and flourishing; the city

was enlarged, and by means of a dam, joined to the temple

of the Olympian Jupiter, ifanding in an ifland. He also

built two temples, one to Hercules and another to Aifarte,

enriching them with donations. Besides erecting a flature

to Hercules, he repaired the temples of other gods, and

dedow them to a very great value. Tatian relates, on the

authority of three Phcenician hiiftorians, that he gave his

daughter in marriage to king Solomon, who, by her influ-

ence, was induced to worship Aifarte, the goddess of the

Sidonians. Hiram, having lived fifty-three years, and reigned

thirty-four, was fucceeded by his fon, and a feries of other

princes, until Nebuchadnezzar, king of Babylon, laid fiege

to the city, in the reign of Ithobal II. 583 years B.C.

This fiege lafted thirteen years (see Ezekiel, xxvi. 8, &c.);

and at laft it was taken by Nebuchadnezzar and utterly

destroyed. Some Phcenician hiiftorians have faid, that Itho-

bal was fucceeded by Baal; nor is it improbable, that the

inhabitants of Tyre, during the fiege, retreated with their

effects to an ifland about half a mile dilant from the shore,

where they built for themfelves a new city; which, after the

deftuction of the old town, submitted to Nebuchadnezzar,

who appointed Bafl to be his viceroy; and that, upon Baal's

death, in order to render the government more dependent

on the Afyrians, he changed the royal dignity into that of

temporary magiftrates, called fuffetes, or judges, 562 years

B.C. After Tyre had been thus governed for some years,

the royal dignity was reftored, and Balat or created king,

556 B.C. Both he and his fucceffors were dependent on,

and tributary to the Afyrians for seventy years; at the

expiration of which they recovered, according to the pro-

phesy of Ifaiah (ch. xxi. 15, 17), their ancient liberty.

In the year 480 B.C., under the reign of Marten, the Ty-

rians, as well as the other Phcenicians, were tributaries to the

Perfians, though they had a king of their own, being fa-

voured by the Perfian monarchs on account of the services

which they rendered to them in their naval expediitions.

About this time reigned Strato, whose afceffion to the throne,

in confequence of an infermifion of the flaves, is particularly

related by Juftin, lib. xviii. cap. 3. He was fucceeded by his

fucceffors, among whom was Azelmie, in whose reign

happened the memorable fiege and reduction of Tyre by

Alexander the Great. This fiege commenced about the

year 333 B.C. which was rigorously carried on and as

obfimately refilled by the Tyrians. At length Alexander,

having battered down the walls, took the city by fire,

322 B.C., after seven months fiege, and fully executed the

sentence which the Tyrians had, by their pride and other

vice,
vices, drawn down upon themselves and their country. The city was burnt down to the ground, and the inhabitants, (tho' whom the Sidonians secretly conveyed away in their ships excepted,) either defrosted or enslaved by the conqueror, who, upon his first entering the city, put 8000 to the sword, caused 2000 of those whom he took prisoners to be crucified, and fold the reed, to the number of 30,000, says Arian, for slaves. His cruelty towards the 2000 that were crucified was highly unbecoming the character of a generous conqueror, and reflects eternal disgrace upon his fame.

After the city was reduced, king Azelmic took sanctuary in the temple of Hercules, and was not only spared by the conqueror, but reforted to the throne, after Alexander had repeopled the place; for having cleared it of its former inhabitants, he planted it anew with colonies drawn from the neighbouring parts; and thenceforth styled himself the founder of Tyre, a city which he had most ungenerously destroyed. From hence, having unchained Apollo, whose statue the Tyrians had fastened, during the siege, with golden chains, to the altar of Hercules, returning him thanks for his intention of coming over to the Macedonians, and offered sacrifice to Hercules, Alexander continued his march into Egypt. This city afterwards regained a considerable degree of power; for in the year 313 B.C. it sustained a siege against Antigonus of fifteen months, before it was compelled to capitulate. It afterwards belonged to several masters, until Antiochus the Great, who took possession of it in the year 218 B.C. It afterwards became subject to the Seleucidae. Cassius, a Roman governor, sold it to Marion, whose wealth enabled him to purchase the principality. Tyre, formerly called Tazor (Josh. xix. 29.), renowned for its trade and the numerous colonies which it transplanted into several parts of the world, and the wars in which its inhabitants valiantly engaged, was in all its glory when Alexander took it, about 300 years after its capture by Nebuchadnezzar. Tyre was still in great repute in the time of our Saviour. (See Matt. xi. 21. xv. 21. Mark, iii. 8. Luke, vi. 17.) It made a considerable figure in the reign of Herod Agrippa, who defigured to wage war against it, if it had not secured peace by its deputies. (Acts, xiii. 20.) When the apostle Paul travelled through this place, it had some Christian inhabitants. (Acts, xxxi. 4.) In the second century it was a bishop's see; and St. Jerome tells us, that in his time it was the most famous and most beautiful city of Phœnicia, and a mart for all the nations of the world. This ancient father alleges this circumstance as an objection to the accomplishment of Ezekiel's prophecy (ch. xxvi. 14.), and replies to it, that the prophet's declaration is to be understood as intimating, that Tyre should no longer be the queen of nations, and enjoy the fame authority and dominion as it possessed under Hiram, and its other kings, but should be subject to the Chaldaans, Macedonians, Ptolemies, and at last to the Romans. Others have suppos'd, that the prophet does not speak of the ruin of Tyre by Nebuchadnezzar, and Alexander the Great, but of its final destruction, of which the other events were forerunners. And indeed Tyre, as we have said, is now only a poor village, inhabited by fishermen (see Str.) so that the prophecy is fulfilled, which declared, "that it should be a place for fishermen to dry their nets on." Ezekiel may also be explained by the prophet Ifaiah (xxiii. 15.), who limits the destruction of Jerusalem to 70 years. But the prophecy of Ezekiel may be more satisfactorily explained, with Mr. Marham, Le Clerc, and other learned authors, who interpret it concerning Old Tyre, i.e. Palæ-tyrus, which flood a little lower on the continent, and the best materials of which were used by Alexander the Great, in making the bithynus which now joins Tyre to the continent. (See Q. Curtius, l. iv. c. 2.) This Tyre was destroyed by Nebuchadnezzar, and never rebuilt. The inhabitants, finding themselves upon the brink of destruction, removed, as we have already said, with their wives and children, and most valuable goods, to the island of Tyre, where they built a city of the name; fo that Nebuchadnezzar, according to the prophecy (Ezek. xxix. 18.), was no gainer by his expedition. The Jews at Tyre, as Josephus informs us, suffered much from the Tyrians. This city was formerly the metropolitan see of the province of Phœnicia. Tyre was transferred to the Arabsians, with the rest of Syria; and before it was reduced to its present miserable state, it was twice besieged by the Christians in the time of the Crusades, viz. in 1112, and again in 1124. It was unsuccessfully attacked by Saladin in 1192; but in 1261, Kabil, sultan of the Mamélukes, obtained it by capitulation, and razed its forts.

TYRESIO, in Geography, a sea-port town of Sweden, in Sodermannland; its sails E. of Stockholm.

TYRI, a lake of Norway, in the province of Aggerhus; 15 miles N.W. of Christiana.

TYRIEUM, in Ancient Geography, a considerable town of Affa, in Phœdia, called alto Tyrus.

TYRINGHAM, in Geography, a town of Maffachusetts, in the county of Berkshire, containing 1689 inhabitants; 140 miles W. of Boston.

TYRIUM MARMOR, a name given by the ancients to a species of marble of a beautiful white, sometimes free from veins, and sometimes variegated with dusky blackish-grey ones. When pure, it was little inferior to the Parian, and often was used instead of it by the flattuaries. See MARBLE.

TYRNAU, in Geography, See TIRNAU.

TIRNAU, a town of Moravia, in the circle of Olmutz; 14 miles N.W. of Olmutz.

TIRNITZ. See Dyrnitz.

TYRNSTEIN. See Dierensteyn.

TYRO. See Tyrocinium.

TYROCRINUM, TYROCRINY, formed of tyro, a raw beginner, a noviciate or apprenticeship in any art or science.

We have several writings under the title of tyrociniums; tyrocinium chyomicum, tyrocinium chirurgicum, &c. containing the rudiments of those arts, accommodated to the apprehensions of beginners.

TYROL, in Geography, a citadel which gives name to the Tyrolean county; 1 mile N. of Meran. N. lat. 46° 37'. E. long. 11°

TYROKEI, or Upper Austria, a county, bounded on the north by Bavaria, on the east by Salzburg and Carinthia, on the south by Italy, and on the west by Bavaria and the Grisons; in this circle are included the county of Tyrol Proper, the bishopric of Trent, and the bishopric of Brixen. The bishopric of Trent is situated to the south; the bishopric of Brixen occupies the north-east part; and the county of Tyrol the centre. This county is mountainous, and capable of making a powerful stand against an invading enemy; but the Tyrolian mountains, though covered with snow to the utmost summits of them, are also fertile, where are found not only the finest woods, abounding in a variety of game, but also large and good corn-fields; or, where these mountains are bare, there are, for the most part, mine works, or excellent marble, of all colours. Corn thrives well in many, many in most places here; and in some places flax. On the eminencies grow also all forts of fine fruits which Italy yields, and likewise small woods of chestnut trees, together with fine vines. Among the wild herbs here
here are chamois and wild goats. There are, likewise, in this county, several species of precious stones, as garnites, rubies, amethysts, and emeralds, a species of diamonds, sapphires, cornelians, chalcedonies, &c. Hot baths and medicinal springs are found in several places; at Hall are profitable salt-pits. Not far from Schvatz is a mine of silver and copper; and some miles distant from the latter is also a mine work, which yields a very soft and melliferous copper. The copper contains in it some silver and gold. Good lead, together with fine mineral strontia, alum, vitriol, and fine ffer, are also found here. The principal rivers in this county are the Ihn, or Inn, the Adige, the Lech, and the Isr. In this county are twelve towns and ten villages, which have markets. The common people here, exclusive of the subsistence which the mines and salt-works yield them, have not much to eat; so that a great part of them seek for subsistence out of the country, either by trade or labour. Tyrol was formerly a part of Rhetia, but, in the sixth century, the greatest part of it defended to the dukes of Bavaria, and this was afterwards reckoned in Noricum; but, over the southern part, the Longobards, at the same time, extended their dominion. The dukes of Bavaria appointed margraves here; but Henry the Lion, duke of Bavaria and Saxony, being, in 1180, put under the ban of the empire, by the emperor Frederic I., this last demifembered the present province of Tyrol from Bavaria, inventing there-with the margrave Berchtold, under the title of duke of Meran. Otto II., grandfion to this Berchtold, dying without male issue, in the year 1245, this county came to count Albrecht III., who resided at the citadel of Tyrol, gave up the title of duke of Meran, and styled the whole country the county of Tyrol. Tyrol had, afterwards, frequently princes of its own, of the house of Austria; the last of whom, named Sigismund Francis, died in 1665, upon which the emperor Leopold received homage on that account, in person, at Inpruck; and by the peace of Prebuff was it ceded to Bavaria. The high foreign colleges over Tyrol, when subject to the house of Austria, were seated at Inpruck; and towards the maintenance of the military state, it contributed yearly 100,000 florins.

TYRONE, a county of Ireland, in the province of Ulter, which is entirely inland, and very irregular in its shape. On the north it has the county of Derry; on the west, Donegal; on the south, Fermanagh and Monaghan; and on the east, Armagh, with Lough-Neagh. Its divisions from these counties are seldom marked by nature, but the river Blackwater bounds it for about 30 miles on the south- east; and, the river Fin and Foyle for about 10 miles on the north-west. The greatest breadth of this county is 43 Irish miles, or 54 English; and the greatest breadth 33 Irish, or 42 English. The area measures 467,700 acres, or 724 square miles Irish, which is equal to 751,878 acres, or 1,663 square miles English. Dr. Beaufort states the number of houses at 28,704, which, at 54 per house, would give a population of near 1,580,000, or about 30 to each square Irish mile. As this was the statement in 1792, the increase must have been considerable. The number of parishes is only 35, and there have 54 churches. Most of these are in the diocese of Armagh, but there are some in the dioceses of Derry and Clogher. Tyrone is represented in the imperial parliament by two members for the county, and one for the borough of Dungannon. The northern part of the county is rough and mountainous. The Cairntogher and Muncasterly mountains occupy a large space; and to the south of these are the high hills called "Bally Bell" and "Mary Grey." These produce very little, being in general wet and spongy. Where, however, gravel or any porous subflance forms the subflatum, the surface is dry and wholesome, and well calculated for pasture. The other parts of the county contain very good land; and some districts are remarkable for their fertility, especially the neighbourhood of Dungannon, extending eastwards towards the Blackwater, and about Cooktown. The produce of this county, and the trade of manufactures, agree in the leading feature of the northern districts. The farms, except in the mountainous districts, are usually small; and the produce in general oats, barley, potatoes, and flax. The linen manufacture is extensively carried on; and it gives a favourable idea of the industry of the inhabitants, to learn from the county survey, that much cultivated ground has been gained from the bogs and mountains. In all parts of this country," said Dr. Beaufant in 1792, "cultivation is creeping, and that not slowly, up the sides of all the hills and mountains that are capable of improvement." In this county, the culture of the grasses called fioria was commenced by Dr. Richardson at Clonfeale, near May, the excellencies of which have been laid before the public in various publications, and have attracted the attention of many eminent agriculturists. Many parts of Tyrone contain large quarries of lime-stone, though it is not generally used for manure. There are also many quarries of free-stone; and good mill-stones are hewn out of detached rocks. It is probable that iron-ore is abundant; but without greater plenty of fuel, it can be of no use. Clay fit for bricks, and for various kinds of pottery ware, is also found in many places. But that mineral which has engaged most attention is coal. At Coal-Island, in the eastern part of the county, coal-works have been carried on with some success. Five pits were working in the year 1800, with the appearance of industry. There seemed, however, a want of encouragement; and the canal, which had been made from this place to the Blackwater, was choked up with mud and weeds. A familiar account may be given of the collieries at Drumglaf, near Dungannon; for those above 140,000/. were expended from the national purse in making canals, independently of private exertions, the object has not been obtained; and the Newry canal, instead of conveying the Tyrone coals to that port, to be shipped for Dublin and other places, supplies the county through which it passes with English and Scotch coal. At the time of making these grants, from 1751 to about 1770, there was a surplus of the revenue, which was spent on various public works, but not always to advantage, and very seldom with economy. In the instance above mentioned, the object was to save the large sums spent annually out of Ireland for coal, or rather to procure a supply of that article on lower terms than it was usually obtained. But though some advantage has arisen from the Newry canal, so great has been the expence attending it, and so complete the failure of all the other parts of the speculation, except for the supply of the adjoining country, as seems to illustrate the opinion, that the interference of government in such plans seldom succeeds, and that the grants intended to encourage them are too commonly abused and perverted. It has been said, that there are indications of a rich coal mine near the village of Drumquin, in the fourth-wheat of the county, and in a district abounding with iron-ore; and as this is only 12 miles distant from Lough Erne, a canal has been recommended; but since the union, and especially since the taxes have preffed so heavily on all ranks, such speculations are not so readily adopted. The report of Mr. Griffith, the mining engineer of the Dublin Society, on the Ulter coal district, will throw much light on the subject; but his opinion, as expressed in his report on the Leinster
Leinster district, is not favourable to the extent or value of that in the county of Tyrone.

The rivers of this county are very numerous, so that it is well supplied with water for bleaching, &c. The principal river is the Mourne, which paffes through the centre of the county from south to north. It rifes in the mountains near Clogher, and receives several streams before it comes to Omagh, where it is joined by the Cameron from the south; and a few miles lower, by the Po from the west. At Newtown-Stewart the united streams of the Moyle, and another river from the mountains between Tyrone and Derry; and at Arddraw the Derg, which flows from Lough Derg, in the county of Donegal, add their fhores. Thence it runs to the town of Strabane, below which it meets the river Fin, from the county of Donegal; and they proceed together, under the name of Foyle, to the sea, being navigable for large boats. The river Blackwater, which is also navigable for about ten miles of its course, is of great service to the eastern part of the county. The Ballinderry paffes by Cookstown, and afterwards becomes the northern boundary, until it flows into Lough Neagh. The other streams are incumberable, and there are no lakes which deferve notice. The towns of this county are not large; Omagh is the county-town, probably on account of its central situation; for it is inferior to Dungannon or Strabane. Dungannon was the principal refidence of the O'Neils, when chief-tains of Ulter. These towns, and Cookstown, May, &c. are mentioned under their respective names. The country and inhabitants near Newtown-Stewart were much improved by the exertions of lord Mountjoy, who was killed at the battle of Rofs in 1708, fighting againft the rebels, at the head of his regiment. His ufeful and benevolent plans have not, however, been neglected. About Fintona good flourifiting and ridge tiles are made, and a great variety of crockery ware for country use. Near Coal-Iland is a pottery, fuppofed to be the birth in Ireland for rough crockery ware, fire-bricks, and tiles for mafk-hins, which are of as good a quality as any imported. The fame clay made into small oblong pieces, and dried in the fun, is ufed for cleaning of leather, &c. and is lent for this purpofe to very ditfant places.

Having this it is an account of the prefent state of Ty- rone, with refpect to its productions and manufactures; it may be added, that when O'Neil, the descendant of the kings of Ulter, was compell'd to submit to queen Elizabith, he was created earl of Tyrone; and when his rebellion, in the reign of James I., occasioned the forfeiture of his po- feffions, this was one of the counties planted, that is, allotted to fettlers, chiefly from Scotland, whose defendants are at prefent the principal landed proprietors.—M'Eway's Survey of Tyrone. Beaouf't Memoir of Map of Ireland, &c.

Tyrone, a township of Pennsylvania, in the county of Adams, containing 648 inhabitants.—Alto, a township of Pennsylvania, in the county of Cumberland, containing 2604 inhabitants.—Alto, a township of Pennsylvania, in Huntingdon county, containing 753 inhabitants.—Alto, a township of Pennsylvania, in Fayette county, containing 986 inhabitants.

Tyrro, a circuit of Hindooflan, in the fubah of Bah- bar, bounded on the north by Morung, on the eafh by Pur- nacah, on the fouth by Bogilpore, on the fouth-west by Hay- pour, and on the west by Bettiah. Durbungah is the capital.

Tyrosis, from τρύζω, formed of τρύς, chief, in Medicine, a coagulating or curdling of milk in the flomach, after the manner of cheese.

Tyrrell, James, in Biography, a political writer and historian, was the fon of Sir Timothy Tyrrell, Kn., of Shotover, near Oxford, by Elizabeth, the only daughter of archbishop Uftter, born at London in 1642, and admitted, in 1657, a gentleman-commoner of Queen's college, Oxford. Devoting himself to the study of the law at the Inner Temple, he was called in 1665 to the bar. But declining the prac- tice of his profEfion, he refided at Oakley, in Buckingham- shire, and studied the history and constitution of his country, of which he entertained more liberal sentiments than those with which he commenced his refearces. In 1691 he pub- lished an anfwer to sir Robert Filmer's patriarchal fcheme, under the title of "Patriarcha non monarapha; or, The Pa- triarch unmonarched." Having refused to affift in the abolition of the penal laws, and the teft againft popery, he was struck out of the commiffion of the peace by James II. As a zealous friend to the Revolution, he vindicated king William's right to the crown in "Fourteen Political Dia- logues," printed from 1692 to 1695; which were afterwards collected into one volume folio, with the title of "Bibliothea Politica, &c." in which all the chief arguments, both for and againft the late revolution, are impartially refpedted and confidered. He also componed an abridgment of bishop Cumberland's work "De Legibus Naturae," 1692, 8vo. of which work a fecond edition, corrected and enlarged, was printed in 1701. But his principal performance was "The General Hiftory of England, both Ecclefaftical and Civil, from the earlieft Accounts of Time," concluding with the reign of Richard II., and comprifed in 5 vols. fol. 1700— 1704. The political purpofe of this work seems to have been to confute the learing doctrines of Dr. Brady, who maintained that all the liberties and privileges of the people of England were confessions from the kings, and derived from the crown; and that the refentment of the commons, as now exifiting, was not introduced before the 45th of Henry III. These points are still controverted, and serve to diftinguish two parties in the flate. Mr. Tyrrell died in 1718, in his 76th year. Biog. Brit.

Tyrrel, in Geography, a maritime county of North Ca- rolina. It contains about 3364 inhabitants.

Tyrrel's Bay, a bay on the south coast of St. Vincent; 2 miles E. of Kingstown.

Tyrrel's Poet. See Tyrrel's Poet.

Tyrrehenia, in Antient Geography, that part of Italy which is now called Tuscany; but more extensive to- wards the north and south-coaft. This country has changed both its name and its inhabitants.

The Umbrians were expelled by the Pelafigi, and thefe by the Lydians, under the conduct of Tyrhenus, the fon of the king of Lydia, whence the name Tyrrenia. As the Tyrrenians were a religious people, and offered many facri- fices, the Greeks called them Thusi, or Thunzi, denoting facrificers, from θυς, to sacrifice. See TURRIA and TUSCANY.

Tyrrehenus Sinus, a gulf of Italy, on the coast of Etruria. According to Dionyfius of Halicarnaffus, this gulf was denominated "Autumnus Sinus."

Tyrtaeus, in Biography, a Greek poet. is fuppofed to have been a native of Miletus, and to have refided at Athens, as a poet, musician, and school-master. Somewhat deformed in body, he poetifed a manly and elevated fent. In a conflft between the Lacedemonians and Meffennians, the former, having experienced fome ill fuccefs, are faid to have confeffed the oracle of Delphi. B.C. 623, and to have been directed to fearch a general at Athens. The Athenians, as some fay in derifion, sent Tyrtaeus, who, by the recital of poems in praise of valour and patriotism, animated the Spartans, fo that they became victorious, and reduced the Meffennians to subjection. He is faid to have give them useful
useful advice as a military leader, in consequence of which
the Spartans conferred upon him the right of citizenship,
and honoured him whilst he resided among them. His war-
poems have been celebrated by the ancients, and particularly
by Horace, who joins him with Homer in his eulogy:

"— Poff hos insignis Homerus
Tyrrænsque mares animos in martia bella
Veribus exsult. —"—Art. Poet.

Besides these poems, he composed, also, "Moral Pre-
cepts," and a work "On the Polity of the Lacedae-
moniens." Some fragments of his "War-Poems" are extant,
which are referred, with the other minor Greek poets, and
are said to be characterized by a marcelline simplicity. Mo-

TYRVANDO, in Geography, a town of Sweden, in
Tavastland: 10 miles N.N.W. of Tavastlin.

TYRVIS, a town of Sweden, in the government of
Abo; 35 miles E.S.E. of Borinorge.

TYRUS, in Ancient Geography, a town of the Pelopon-
nesus, in Laconia.—Alfo, a town of Asia Minor, in Lydia.
—Alfo, an island settled on the coast of Syria, near the
continent, according to Tulemy.—Alfo, an island settled
in the Persian gulf. Strabo.

TYRUS, a word used by some of the barbarous writers
for a serpent or viper.

TYRWHITT, Thomas, in Biography, a profound
scholar and acute critic, was born in 1730, sent to Eton
school in 1741, and entered at Queen's college, Oxford,
in 1747. In 1755 he was elected fellow of Merton college,
and in 1756 acted as under secretary of war. In 1762
he became clerk to the house of commons, which post he
retained till the year 1768. At this time he retired to pursue
the life studies which were adapted to his genius and taste,
and to the requirements he had already made in the knowledge
of ancient and modern languages, and of the old as well
as modern writers of his own country. He commenced his
publications with compositions in poetry; such were "An
Epistle to Florio," and Latin versions of the "Mellisah"
and "Splendid Shilling," with an English one of "Pindar's
eighth Ithilian Ode." In 1766 appeared his "Observations
and Conjectures on some Passages of Shakspere," which
e-enabled him to communicate ingenious remarks to Mr.
Steevens and Mr. Reed, for their editions of the works of
this great dramatist. His "Proceedings and Debates in the
House of Commons in 1620 and 1621, from an original
MS. in Queen's College, Oxford," appeared in the same
year; and in 1768 he published a corrected and enlarged
edition of "Ellynges's Manner of holding Parliaments in
England." His first publication in critical literature was
"Fragmenta duo Plutarchi," 1773, from one of the Har-
leyan MSS. This was followed by a very valuable edition
of Chaucer's "Canterbury Tales," in 4 vols. 1773, which,
besides corrections of the original text, contains an intro-
duction and admirable essay on the author's language and
verification. In 1776, he further displayed his Latin erud-
tion and critical acumen, by a Latin dissertation on Babrius,
one of the writers of the Elegiæ fables. In 1777 he gave
a complete edition of the poems attributed to Rowley, with
a preface and glossary. In a subsequent edition, which
appeared in 1778, he expresses his full conviction, with the
grounds of his opinion, that they were written solely by
Chatterton, and he afterwards satisfied all unprejudiced
judges with regard to this subject of literary controversy.
(See CHATTERTON.) We shall merely enumerate his re-
mainings works, which were, an edition of a Greek poem,
Πίπο Αίδων (on Stones), ascribed to Orpheus, together
with a supplement to his dissertation on Babrius, 1781;
"Conjecturae in Strabonem," 1783; and a newly discovered
"Oration of Iaicus against Menocles," 1785. Mr. Tyrwhitt
was a member of the Royal and Antiquarian Societies, and
a curator of the British Museum. He died, much lamented,
in 1786, in his 56th year; having established a character that
was truly estimable. He bequeathed to the British Museum
all those of his books which were not before in that re-

TYSCA, in Ancient Geography, a country of Africa,
in which there were fifty towns. Maffimia and the Carthagin-
iens disputed the possession of this country, and the dispute
was referred to the senate of Rome, according to Appian.

TYSERRA, in Geography, a town of Hindostan, in
Bihar; 32 miles S. of Dofea.

TYSHAS, among the Ethiopians, the name of the
fourth month of their year, commencing the 27th of No-
ember in the Julian year.

TYSNASOE, in Geography, a small island in the North
sea, near the coast of Norway. N. lat. 60°.

TYSSENS, Peter, in Biography, was born at Ant-
werp in 1625, and practiced painting in portraiture and his-
tory with very great success. In the latter, however, he
acquired the most substantial portion of his fame; and after
the death of Rubens, he was made director of the Academy
at Antwerp. He died in 1692, aged 67, leaving two sons painters.

TYSTED, in Geography, a town of Denmark, in North
Jutland, situated on a river which runs into the Limfodd
gulf; 40 miles W. of Aalborg. N. lat. 57° 3'. E. long.
8° 45'.

TYTSAARSl, a round island of the Baltic, belong-
ing to Russia: it is pretty high, but not above ten versts in
circuit. It lies 18 versts to the S.E. of Hochland. As ap-
pendages, on the western side, or in the Sound, between it
and Hochland, it has four small isles, quite low, but pretty
far afunder: Kleintitter, the two Viri, and Væotcalla, and
on the southeren side a flody ground, seven or eight versts in
length, to the Narva palfage; hence, it is hardly possible
to land on this island. A third part of it is rock, another
third is morafs, and the remaining part an arid and sterile
sand-hill. The island has no springs. The seal-fishery is
here considerable: the inhabitants live together in one
village.

TYTH, or rather Titha. See TITH.

TYTHING, and Thing-man. See TITHING, DECI-
NERS, TENEMENTAL, HUNDRED, WAPENTAKE, &c.

TZAGANUSKOI, in Geography, a town of Russia,
in the government of Irkutk, on the borders of Chine; 48
miles S.S.W. of Selengirk.

TZAGONIA, a district in the fourth part of the Morea,
between Mistra and Cape Malio.

TZAMAMIEN, a town of Asiatic Turkey, in the
government of Marafch; 40 miles S.E. of Marafch.

TZAMANDUS, in Ancient Geography, a town of Asia,
in the vicinity of the Lesser Armenia.

TZANATL, in Ornithology, the name of an American
bird described by Nieremberg, which, he says, has all over
very long and beautiful feathers, of a fine green, and of the
finishing glos of the feathers of the peacock. The upper fide
side of the wings is black, but their under part is of a very fine and shaded green; it has a very beautiful crest on its head; its throat and breast are of fine scarlet; the wing-feathers are very long, and very beautifully variegated with several colours. The Indians esteem the feathers of this bird more valuable than gold; they dress up the images of these birds with them. Ray's Ornithol. p. 503.

TZANGAE, among the Ancients, a kind of Parthian garments, according to some; but others will have them to have been shoes set with precious stones, formed into the figure of eagles, and designed for the emperor's use.

TZANI, in Ancient Geography, a people of Asia, in the vicinity of Armenia. According toProcopius, they were formerly independent, and lived a savage life; worshipping birds and other animals, and inhabiting mountains covered with thick and dark forests. They paid no regard to agriculture, and had neither corn nor pastures, so that the culture of the soil was wholly neglected. They had no restraint on their liberty, till they left it under Juffanian, to whom they voluntarily surrendered themselves. In process of time they embraced Christianity, which produced a total change in their manners and habits. They afterwards served in the Roman armies. Juffian contributed, by the regulations which he introduced, to civilize them. But some authors say, that at this day the Tzanius have no kind of religion; that they have neither temples, nor altars, nor priests, nor any worship.

TZANPAU, in Ornithology, the name of an American bird described by Nieremberg, and famous for the modulations of its voice, and is by many esteemed the female of the polysyllaba avis, or concanatolisi of the Indians.

TZAREVAGOR, in Geography, a town of Russufa, in the government of Tobolik; 28 miles S.E. of Okunevok. N. lat. 55° 20'. E. long. 64° 34'.

TZAREVOKOKCHAIISK, a town of Russufa, in the government of Kazan; 68 miles N.W. of Kazan. N. lat. 54° 52'. E. long. 47° 34'.

TZAREVOSANGUURSK, a town of Russufa, in the government of Viatka; 100 miles S.W. of Viatka. N. lat. 57° 48'. E. long. 47° 54'.

TZARI, a town of the principality of Georgia, in the province of Kakot; 95 miles S. of Tefs.

TZARITZIN, a town of Russufa, in the government of Saratow, on the Volga, defended by a ditch and rampart, with artillery and a considerable garrison; 180 miles S. of Saratow. N. lat. 48° 35'. E. long. 44° 34'.

TZEKINSKOI, a fortress of Russufa, in the government of Irkutik; on the borders of China; 100 miles W.S.W. of Selenginsk.

TZEPETH. See Safad.

TZERIMISH, a horde of tarts, pretty numerous, in the neighbourhood of Kazan.

TZERNA, a river of Romania, which runs into the Mariza, near Tvernitz.

TZERNITZ, a town of European Turkey, in Romania, near the Tzerna; 52 miles N.N.E. of Adrianople.

TZERVINKA. See Zervinka.

TZETZES, John, in Biography, a Greek poet and grammarian, flourished in the twelfth century, and was distinguished by his talents, natural and acquired, and particularly by a retentive memory, inasmuch that he had the whole Scriptures by heart. He was the author of "Allegories on Homer," and of "Miscellaneous Histories," in thirteen chilliads, written in that lax kind of verse which is called polite, or popular. The characteristics of this poet, lays one of his biographers, appear to be tediousness and infi-

TZU

pidity with arrogance. As a critic, he gave scholia upon Hesiod. His Allegories were published by Morel, Paris, 8vo. Gr. and Lat., with notes, 1616; and his Histories or Chillidae at Bali, fol. 1546.

The brother of the preceding, ISAAC Tzetzes, published learned commentaries on Lycephoron, which have been considered as the joint productions of both brothers: they are reprinted in Potter's edition of Lycephoron, Oxon. 1657. Morel. Gen. Bing.

TZICATLINA, in Zoology, a species of serpent, found to be found in America, and reckoned among the most beautiful of that kind of animals. It is nine inches long, about the thickness of a man's little finger, and variegated with alternate swaths of white and red crossing its body. It is likewise one of the harmless kind of serpents.

The name signifies the serpent of ants, because it lives always in their nests, and comes out along with them.

TZIECHANOW, in Geography. See Chekanow.

TZIEL, a town of the duchy of Warfaw; 35 miles W. of Pofen.

TZIGENO, a town of Crotia; 10 miles S.E. of Creutz.

TZIKIRSKOII, a fortress of Russufa, in the government of Irkutik; 120 miles W.S.W. of Selenginsk.

TZILEI, a town of Walachia, on the Danube; 20 miles W. of Nicopolii.

TZIMLIANKA, a town of Russufa, in the country of the Cofacks, on the Don; 116 miles E.N.E. of Azoph.

TZINTZIZIAN, in Ornithology, the name of a very beautiful American bird, described by Nieremberg, of the size of a small pigeon, and ornamented with variously-coloured feathers. The beak is short, crooked, and of a pale colour; the head and neck are like those of the pigeon; the breast and part of the belly are red; but that part which is next the tail is of a fine elegant blue, and a bright white, beautifully intermixed with one another; the tail is green on the upper part, and black underneath; the wings are variegated with white and black; the feet and legs are grey, and the shoulders of a very beautiful green. It is most frequent near the South Sea, and feeds on vegetables. It is kept in cages for its beauty, but never fings. The Indians make several beautiful works of its feathers. Ray's Ornithol. p. 303.

TZIOURLY, in Geography. See Tsordii.

TZIVILSK, a town of Russufa, in the government of Kazan; 56 miles W. of Kazan. N. lat. 55° 40'. E. long. 47° 34'.

TZNA, a river of Russufa, which rises 20 miles S. of Tambow, and runs into the Molchka; 25 miles N.W. of Temnikow, in the government of Tambow.

TZTACTZON, in Ornithology, an American name, under which Nieremberg has described a species of duck, remarkable for the varieyied and beautiful colours of its head, which are purple, blue, white, and green, and shine like fatin; its body is variegated with black, grey, and white; its legs are red, and is eaten as the other water-fowl. It is common in the lakes of Mexico, and has been much more adapted to swimming than to walking. Ray's Ornithol. p. 299.

TZURUCHATU, Sthan, in Geography, a town of Russufa, in the government of Irkutik, on the Argonia, on the borders of China. This is one of the towns in which a private trade is carried on between the Russians and the Chinese. It has a small garrison; 150 miles S.E. of Nertschinsk. N. lat. 49° 18'. E. long. 119° 32'.
U. and V.

V A A

Besides the vowel u, there is a consonant of the same denomination, wrote v or v.

V, a consonant and U vowel ought to be considered as two letters; but as they were long confounded while the two uws were annexed to one form, the old custom still continues to be followed.

U, the vowel, has two sounds; one clear, expressed at other times by eu, as obtine; the other elofe, and approaching to the Italian u, or English oo, as obound.

V, the consonant, has a sound nearly approaching to thoite of b and f. With b it is by the Spaniards and Gaccons always confounded, and in the Runic alphabet is expressed by the same character with f, distinguifhed only by a diacritical point. The found in English is uniform: it is never mute.

V is also a numeral letter, and signifies five; according to the verfe,

"V vero quince dabit tibi, si recte numerabis."

When a dash was added at top, V, it signified 5000.

V. R. among the Romans, froid for uti rosas, as you define: which was the mark of a vote, or suffrage for the paffing of a law.

The following abbreviations fometimes occur; vix. V. A. for veterani assignati; V. B. vero bono; V. B. A. viri boni arbitratus; V. B. F. vir bono fidei; V. C. vir confidibus; V. C. C. F. vale, conjux charifime, feliciter; V. D. D. voto dedicatur; V. G. verbi gratia; V. L. videlicet; V. N. quintus nonarum.

V, on the French coins, denotes thoite that were flucc at Troyes.

V, in Music, besides its numerical import of five, in ancient madrigals implies quinta pars, a fifth part added to the treble, counter tenor, tenor, and bafe. In instrumental music it bands for violin, as V.V. do in the plural for violins. V. S. are the initials of vero fubito, Lat. ; and voli fubito, Itala, for turn over quick.

VAAGEN, East, in Geography, an island in the North sea, 20 miles from the coast of Norway. N. lat. 68° 26'V.

VAAGEN, West, an island in the North sea, 30 miles from the coast of Norway. N. lat. 68° 12'.

VAAGSOE, a small island in the North sea, near the coast of Norway. N. lat. 61° 57'.

VAARSOE, a small island of Denmark, on the E. coast of Jutland, at the mouth of the gulf of Holfens. N. lat. 55° 53'. E. long. 10° 1'.

VAAS, a town of France, in the department of the Sarte; 21 miles S. of Le Mans.

V A C

VAAST, St. See St. Vaast.

VABAR, in Ancient Geography, a town of Africa, on the coast of Mauritania Cafreriflfs. Ptolem. VABAR, Abl-oane-man-bar, a promontory of the easter part of Mauritania Cafreriflfs. Ptolem. The port Salde, mentioned by Strabo, lay S.E. of this promontory.

VABB, a town of Africa, in Mauritania Tingitana, formerly sometimes denounced Julia Campestris.

UABE, in Geography. See HIBAL.

VABELIRAKE, an island in the Red sea. N. lat. 25° 8'.

VABRES, a town of France, in the department of the Aveiron, at the union of two small rivers, which soon after run into the Tarn. Before the revolution, it was the seat of a bishop, suffragan of Alby; 2 miles S.W. of St. France.—Allo, a town of France, in the department of the Cantal; 4 miles E. of St. Flour.

VACAN, one of the small Philippine islands, near the N. coast of Samar. N. lat. 12° 47'. E. long. 121° 15'.

VACANCY, in Philosophy. See VACUUM.

VACANCY, in Law, &c. a post or benefice wanting a regular officer, or incumbent.

The canons hold, that the kind of vacancy is to be expressed in the impetration of a benefice.

A future vacancy, or voidance of a spiritual living, some writers call vacatuta. Devolution is a species of canonical vacancy.

Vacancy of the Throne. See Right of Crown, and Revolution.

VACANT Effects, Pradia Vacata, or Vaca, are such as are abandoned for want of an heir, after the death or flight of the former owner.

In our law-books, vagantes terras, for vacantes, express forfaken or uncultivated lands.

A Romish benefice is said to be vacant in curia Romana, when the incumbent dies in Rome, or within twenty leagues of it; though it be only by accident that he was there. The pope nominates to all benefices vacant in curia Romana, excepting those of the neighbouring bishoprics.

VACANT Cylinder, in Gunery. See CYLINDER.

VACARIA, Aucaria, or Caucaria, in Ancient Geography, a place of Africa Propria, on the route from Hippone to Carthage, between Vicus Augusti and Tuburbo Minus, according to the Itinerary of Antonine.

VACARIA, in Geography, a town of Egypt; 8 miles N.E. of Habateh.

VACARICA, a town of Portugal, in the province of Beira; 18 miles S.E. of Bragança.

VACAS, a river of Mexico, which rises in the province of Guatemala, and runs into the Pacific ocean, N. lat. 14° 22'. W. long. 92° 48'.
VAC

Vacas Bay, a bay on the S. coast of Africa. S. lat. 34° 15'.

VACAUSA, a small island near the W. coast of Lewis. N. lat. 58° 11', W. long. 6° 57'.

VACATAMA, a river of Peru, which runs into the Pacific ocean, S. lat. 9° 25'.

VACATING RECORDS, in Law. See IMPEZZALE.

VACATION, Non-term, all the time included between the end of one term, and the beginning of the next succeeding one. See TERMS.

This intermission was called by our ancestors pax Dei, and ecclesia; and sometimes, the time or days of the king's peace. Among the Romans, it was called jussicium or feria, or diet nefalia.

The time from the death of a bishop, or other spiritual person, till the bishopric, or other dignity, be supplied by another, is also called vacation.

During the vacation of a bishopric, the dean and chapter are guardians of the spiritualities, by the canon law; and of common right they are so at this day in England, and the archbishop hath this privilege only by prepetition or composition, to whom with us, during the vacancy of any fee within his province, all episcopal rights of the diocefe belong; and all ecclesiastical jurisdiction is exercised by him and his commissaries. But when an archepiscopal fee is vacant, the dean and chapter of his diocefe are guardians of the spiritualities, and exercise the spiritual jurisdiction of his province. And the perquisites that happen by the execution of fuch power belong to the guardian, but the new-elected bishop may by law, after election and confirmation, execute the same. See Custos Spiritualudum.

The custody of the temporalities of every archbishopric and bishopric within the realm, in the time of vacation, belong to the king, by his prerogative; and upon the filling of a void bishopric, the king, and not the new bishop, hath the temporalities of it from the time that the vacant became void to the time that the new bishop shall receive them from the king; which the king ex gratia may grant him by his letters patent after his confirmation, and before his consecration; but after he is consecrated, invested, and invested, he may sue for his temporalities out of the king's hands by a writ directed to the effirector; the metropolitan testifying the time of consecration. See Custos Temporaludum.

During the vacation of a benefice, the profits, by the common law of the church, were to be laid out for the benefit of the church, or referred for the feecfor; and by special privilege or custom the bishop or archdeacon might have the same, wholly or in part: and it is said, the king might take the profits of a free chapel, and the patron thofe of a donative. But by statute 28 Hen. VIII. c. 11. it is enacted, that the tithes and profits of spiritual promotions, offices, benefices, and dignities, during the time of their vacation, shall belong to the person next preffented, promoted, instituted, inducted, or admitted, towards the payment of his first-fruits. Ancientsly, upon the death of an incumbent, the rural dean, without any formal fequeration, took the vacant benefice into his custody; but in proffes of time, the chancellors of bishops, or their archdeacons, laid claim to this jurisdiction, and by forms of fequeration assigned vacant churches to the economi or lay guardians of the church; and now the ordinary mode of managing the profits of vacation is by sequeration granted to the church-wardens, who are to manage all the profits and expences of the benefice for the feecfor; whose right to the profits commences from the voidance of the benefice, and to whom the sequestrators are to account for such as they have received, deducting their reasonable expenses, and those of supplying the cure during the vacation. By 28 Hen. VIII. c. 11. an incumbent before his death may make his testament of all the profits of the corn growing upon glebe lands which he has manured and fown; but if his successor is inducted before the feuerance of it from the ground, the successor shall have the tithes of it; otherwise, if the parson dies after the feuerance of it, and before it is carried off, the successor shall have no tithes. Where there is no proper leave of tithes, the parson who receives them shall be accountable to the executor for thofe received by him, and which became due before the incumbent's death, and to the successor for tithes which he received, and which became due after the incumbent's death; but glebe lands, and tithes demifed or leafed, are comprehended under statute 11 Geo. II. c. 19. which enacts, that the executors or administrators of a tenant for life may, in an action upon the cafe, recover of the under tenant, if such tenant for life die on the day on which the rent was made payable, the whole, or if before fuch day, a proportion of fuch rent, according to the time fuch tenant for life lived, of the laft year, or quarter of year, or other part in which the faid rent was growing due. As to modus in lieu of the unexpired term, if taken in kind, would have been due before the death of the incumbent, whereas the modus for the fame is not due till after his death, it seems that the executors are not entitled to the faid modus, nor any part thereof, but that the whole shall go to the successor.

 Cicero, in his Orations, mentions a law, by which the priests were exempted from service in all wars, except only in uparos, and civil tumults; which exemptions he calls vacations.

VACCA, in Ancient Geography, a town of Spain, in the Pyrenean mountains, according to Isidore.

VACCA, Vaga, Bota, or Vagenos Oppidum, thus differently named by Sallust, Polonius, Plutarch, and Pliny, Bay-jab, a town of Africa, in Numidia, to leagues from Meternus Oppidum. According to Sallust, it belonged to Jugurtha, and he says, that when it revolted, he established it in Italians. Metellus was sent to reduce it.

VACCA, or Vaca, a river of Spain, in Lusitania, which pursuing its course from E. to W. passed to Talabriga, and soon after ran into the sea.

VACA, La, in Geography, a small island in the Mediterranean, near the S. coast of Sardinia; 3 miles S. of St. Antonico.

VACA, in Zoology, the female of the ox-kind. See Cow.

VACA Marina. See Sea-Cow.

VACCARIA, in Botany, so named from vacca, a cow, because, according to Ambrofius, cows are fond of the plant. His Vaccaria, like that of Dodonæus and Gerarde, is the Linnaean Saponaria Vaccum, referred by the writer of this to Gypsophila, see that article; with which genus its bell-shaped angular calyx, roundish capule, and whole habit, accord so exactly, that we are at a loss to account for Linnaeus's having placed it elsewhere. The Vaccaria of Tavernænamontan is very different, being our Taurus glabra; an herb agreeing with the former in the glaucous, smooth, entire leaves, of its stem at leaf, but otherwise having no character or property in common therewith, and certainly of too unfrequent occurrence, as well as of too slender a habit, to afford much support for a dairy. The above Gypsophila belongs to a natural order of plants to which farmers have, as yet, faintly recurred for any sort of fodder, the Comption tribe. Might not the same before us authorize an experiment at least, upon the qualities of this plant, as well as on thole of its near relation Silene inflata? Speculæ arvenses, 3 T 2, one.
VACCINATION.

one of this order, is reported to enrich the milk of cows, but has not come into any general notice. See Silene, sect. 2, and Spergula, n. 1.

VACCARY, Vaccaria, in our Old Writers, a house or place to keep cows in; a dairy-house, or cow-pasture.

VACCEI, Vacceans, in Ancient Geography, a people of the interior of Hither Spain, S. of that part of the country which was inhabited by the Aeturi. According to Diodorus, the Vacceans were the most gentle and politic of the Celtiberians. They were subjugated by L. Lucullus and Ch. Marcellus. It appears that they were a considerable people by the number of towns which Ptolemy assigns to them.

VACCINATION, or the Cow-pox inoculation, in Surgery, one of the greatest and most important discoveries of modern times. The discovery of the circulation of the blood, made by the celebrated Harvey, has unquestionably been the source of infinite improvement in every part of the healing art, and produced incalculable benefit; but vaccination, the discovery of another Englishman, the immortal Jenner, is a thing, which in its consequences certainly outdoes every previous innovation in practice, since it may be said to have annually the lives of millions.

Vaccination being the only known means of arresting altogether the fatal ravages of the small-pox, the most depopulating contagion upon the face of the earth, mankind will probably for ever feel a deep interest in the subject. In fact, nothing less than the well-established total extermination and permanent cefation of the small-pox, could ever justify a diminution of the laudable solicitude of the public for the continuance of vaccination. For it is not to be presumed, that a still milder and more effectual means of rendering the human body insusceptible of the effects of the small-pox contagion, will ever be discovered. A milder method, indeed, is hardly conceivable; since the symptoms produced by it amount only to a very slight indisposition, which never has any fatal or unpleasant consequnences. Its efficacy also is now fully confirmed by abundance of evidence, collected from the unied observations and experience of the best informed practitioners, who, it is obvious, can have no interest in the success of vaccination, but the general good of their fellow-creatures. Were medical men so base as to suffer their judgment to be influenced by mercenary considerations, they would decry with all their force the practice of vaccination, which occasions too trifling an indisposition to put many fees into their pockets; and they would necessarily praise the small-pox inoculation, by which a frequently long and lucrative attendance on their patients might be calculated upon as a matter of certainty.

A general account of the origin of vaccination has been delivered in the article Cow-pox, and on this interesting part of the subject we shall therefore merely recapitulate a very few particulars. As, however, it is an object of the frill-rate importance to be perfectly acquainted with every criterion of the genuine disease, we mean to introduce into this article some valuable instructions, which have been published by the lately and best medical writers, or which have been circulated by the National Vaccine Establishment, respecting the appearances of the true affection, and of some others, which are either spurious, or not to be depended upon. In this account will be comprehended a brief explanation of the method of practising vaccination. The rest of the article will be principally devoted to the consideration of the occasional failures to which the practice is liable.

It was an observation made long ago in several of the dairies in England, particularly in those in Gloucestershire, that the milk cows were frequently affected with an eruption upon their udders and teats, which was communicated not only from one cow to another, but frequently also to the hands of the milkers; and farther, that such of the milkers as had been thus affected, were never afterwards infected with the small-pox, either by inoculation, or by exposure to the most virulent contagion of that disease, even although such persons had not previously undergone that dreadful malady.

It is curious, that the knowledge of a fact so singular a nature, and one of so much importance to the general interests of society, should have been confined, from time immemorial, almost entirely to those occupied in the business of dairies, without being fully investigated by such persons as could duly appreciate its value.

Dr. Jenner, a physician at Berkley, in Gloucestershire, was the first person who set himself about examining this subject with that care and attention which its importance seemed to demand.

In the year 1798, after much diligent labour and investigation, Dr. Jenner published "An Inquiry into the Causes and Effects of the Variolae Vaccinae," and his observations soon excited the attention of the whole medical world. For a considerable time, the accuracy of the account was received among medical men with hesitation. The character, however, of Dr. Jenner, and the singularity and importance of the subject, led to further investigation; and although many arguments were urged, and circumstances stated, which seemed adverse to the plan of the general introduction of cow-pox among mankind, yet the great utility of it was at last clearly evinced. Every statement made by the accurate Jenner was confirmed, and the credit of the cow-pox, as a preventive of small-pox, was established on a basis too firm to be shaken by the shafts of envy, malice, or ignorance—the basis of immutable truth.

Dr. Jenner, not satisfied with the affections of the dairy farmers and servants, that persons who had been affected with cow-pox were rendered thereby secure against the attacks of small-pox, determined to ascertain the truth of this fact by the test of experiment. He inoculated for small-pox many persons who had formerly undergone the cow-pox, some for as long as thirty and even fifty years previously; and these he uniformly found, as had been predicted to him, completely refitted that disease.

So far the nature of cow-pox was known to others before it was known to Dr. Jenner. In the year 1796, however, this ingenious gentleman pushed his investigation farther; and on the 14th of May, he first intentionally infected the human constitution with the virus of cow-pox by inoculation, with the design, as he informs us, of observing more accurately the progress of the infection. The experiment succeeded; and the affection, though remarkably slight, was clearly marked in all its stages.

Dr. Jenner next conceived the idea of inoculating this person with the virus of small-pox, in order to ascertain whether he should an affection as had taken place from the cow-pox, could possibly give security from that dreadful disease. Several flight punctures and incisions were accordingly made in both arms, and the virus of small-pox was carefully infected, but no disease followed. Some months afterwards, the same person was again inoculated for small-pox, but still no sensible effect was produced upon the constitution.

This is to be reckoned the first discovery of Dr. Jenner respecting the nature of cow-pox, viz. that the matter of cow-pox, taken from the vesicles on the cow, and intentionally infected into the human subject, produces an affection,
VACCINATION.

tion, which, at the same time that it is more mild in its symptoms than that produced by accidental infection, does nevertheless ill operate such a change in the constitution, as renders the person infected unsusceptible of the small-pox.

The want of vaccine matter now prevented Dr. Jenner from prosecuting his experiments until the spring of the year 1798, when the cow-pox again became prevalent among the cows in the dairies in his neighbourhood, and afforded him an opportunity of investigating farther this interesting subject.

With matter taken from cow-pox vesicles on the teats of a cow, Dr. Jenner now inoculated several persons; and from these persons he propagated the affection to others, also by inoculation, even so far as the fifth change, without recurring to the original source, the vesicles on the teats of the cow. The experiments were completely successful. The affection, in all those inoculated, was regularly produced. All the persons who had been thus infected, were afterwards subjected to inoculation with the virus of the small-pox, but ineffectually, no disease in any instance succeeding to this operation. See Jenner's Inquiry, p. 43.

From these experiments, we derive another most important fact concerning the nature of cow-pox, viz. that the virus of cow-pox may be propagated from one human subject to another, through several gradations, and still retain the power, not only of producing the affection, regular in all its stages, but also of rendering those constitutions which are infected, secure against the attacks of small-pox.

By un wearied attention to all the circumstances under which he was accustomed to observe this ailment, Dr. Jenner was led to conclude, that persons who have already had the small-pox, are still susceptible of the action of cow-pox, though not to such a degree as those who have never been subjected to that of small-pox.

That in the cow-pox no eruption takes place, unless on the part where the virus is applied to the skin.

That the cow-pox, even under the most unfavourable circumstances, has never proved fatal.

That the cow-pox cannot be propagated by contagion, but only by actual contact, or inoculation with the virus.

That the virus of the cow-pox, infected into the human body, may produce an affection which is merely local, the general constitution remaining unaltered; and that, in such cases, the person is still liable to be infected with the small-pox.

Soon after Dr. Jenner's publication appeared, viz. in November, 1798, Dr. George Pearson published "An Inquiry into the History of Cow-pox, principally with a View to supercede and extinguish the Small-pox." In this treatise, the positions and conclusions of Dr. Jenner are examined with that candour and attention, which their importance demand. The evidences adduced are numerous and respectable, and the refutation is highly favourable to the general introduction of inoculation for the cow-pox among mankind, not only as a preventive of small-pox, but also as a certain mode of ultimately extinguishing that loathsome malady.

In May, 1799, were published "Reports concerning a Series of Inoculations for Cow-pox, with Remarks and Observations on this Diseaee, considered as a Substitute for Small-pox, by Dr. Woodville, Physician to the Small-pox and Inoculation Hospital in London." The account here given by Dr. Woodville is very different from that given by Dr. Jenner, and by no means favourable to the general introduction of the new inoculation as a substitute for small-pox. Such a report, coming from a man of Dr. Woodville's known character and reputation as an accurate observer, naturally produced a strong sensation in the minds of medical men concerning the discoveries of Dr. Jenner. The circumstances, however, under which Dr. Woodville's observations were made, and upon which his reports were founded, were such as led him to be much deceived respecting the true nature of the cow-pox.

This report of Dr. Woodville, so very different from the general statement of Dr. Jenner, naturally called for a reply from the latter, who accordingly, in 1800, published "A Continuation of Facts and Observations relative to the Variola Vaccinae." In this publication, Dr. Jenner is anxious to recover his favourite subject from that degree of shade, which had been thrown upon it by the hasty reports of Dr. Woodville; and this he appears to have done with great success, both by farther observations of his own, and by the concurrence of many respectable correspondents. See Bryce's Practical Observations on the Inoculation of Cow-pox, chap. 1, edit. 2.

With regard to Dr. Woodville's publication, we shall merely add in the present place, that the cafes reported by him as examples of inoculated cow-pox, attended with many severe symptoms, and particularly with an eruption over the body, have been fully proved, and indeed have been since allowed by that respectable physician himself, to have been in fact cafes of genuine small-pox, the infection having been contracted in the place where the patients were inoculated with cow-pox virus, before this latter affection had produced the effects and changes in the constitution, which render it a preventive of the other loathsome malady.

For additional particulars relative to the first progress of vaccination, we must refer to the article Cow-pox; suffice it here to say, that every objection to the practice was gradually removed; the public became convinced of its value and beneficial consequences; the great founder of it received an honourable remuneration from his country; both neighbouring and remote nations soon took a deep interest in the subject, and imitated our example; public institutions for the gratuitous inoculation of the poor were in a short time established in every civilized country; and the great benefit of the new plan were quickly extended to all the four quarters of the globe.

Description of the regular vaccine Vesicle.—When vaccination succeeds, a small red spot is observable on the third day, the day upon which the operation is performed being reckoned the first. If the spot be touched, an elevation is felt; and if examined with a magnifying glass, the little tumour appears to be surrounded by a very slight cell-refence.

The spot gradually enlarges; and between the third and fifth day, a circumscribed vesicle appears. The edge of the vaccine vesicle is elevated; the centre depressed. The colour is at first of a light pink, sometimes of a blueish tint, and changes by degrees to a pearl colour. The centre is somewhat darker than the other parts.

The vesicle is hard to the touch.

In its internal structure it is cellular, the cells being filled with transparent lymph.

The vesicle commonly augments, till the tenth or eleventh day.

In the early stages, there is usually round the base an inflamed ring; or this takes place on the seventh or eighth day. About the ninth, it spreads rapidly; and near the tenth, it forms an areola of an inch and a half in diameter. This areola is of the usual colour of inflamed skin; it is hard, and accompanied with some degree of tumefaction. It
VACCINATION.

It continues out for a day or two, and then begins to fade, sometimes forming two or three concentric circles. After the areola is formed, the vesicle begins to decline. The centre first turns brown, and the whole gradually changes into a hard smooth scab, of a very dark mahogany colour. This dry crust usually drops off about the end of the third week, leaving a permanent circular cicatrix, about five lines in diameter, and a little depressed; the surface being marked with very minute pits, or indentations, denoting the number of cells of which the vesicle had been composed.

Varieties in the Progress and Appearance of the Vaccine Vesicle, not Preventing the Success of Vaccination.—The first appearance is seldom earlier, but often later, than has been described. In some rare instances, the vesicle commences even a fortnight or three weeks after vaccination; and if the progress is then regular, it is equally efficacious.

When the vesicle is ruptured at an early period, if the progress continue regular, success is not prevented; nor is it when the crust of a regular vesicle is rubbed off in the decline of the disease, though ulceration should ensue.

Of irregular and imperfect Vesicles and Pustules, which are not to be depended upon.—In thedeviations, there is usually a premature itching, irritation, inflammation, vesication, or suppuration; or the progress of the vesicle is too rapid, its texture soft, its edge not well defined, its centre elevated, and the contents discoloured or purulent; or, instead of a proper areola, a premature efflorescence of a dusky purple hue takes place, and the scab is of a light brown or amber colour.

The irregular vesicle or pustule is more liable to be broken than the other, both from its more pointed form and softer texture, and also from its being usually so irritable as to provoke scratchings. When broken, or even without this happening, ulceration often ensues.

A vesicle, apparently regular at first, sometimes does not augment to the proper size, but dies away without completing the regular process. This usually leaves no cicatrix, or one which is almost imperceptible.

When these, or any other considerable deviations from the regular course of the disease, take place, no dependence can be placed upon the operation, and vaccination should be repeated.

Probable Causes of irregular Vesicles and Pustules.—These accidents may be occasioned by matter or lymph being taken from an irregular vesicle or pustule at any period, or from a regular vesicle, at too late a period; by lymph, though originally pure, which has been injured by long keeping, by heat, or otherwise. Or it may be caused by performing the operation with a rusty or unclean lancet, or in a rude manner, or by destroying the vesicle at an early stage, and thereby exciting too much inflammation, or interrupting the regular progress of the disease. Herpetic eruptions, and other cutaneous affections, have also been supposed to be the cause of these irregularities; and occasionally to prevent the vaccine lymph having any effect.

As Dr. Bateman observes, there are two causes for these imperfect inoculations: "the one is the infection of effete or corrupted virus; and the other the presence of certain cutaneous eruptions, acute and chronic.

"The lymph of the vaccine vesicle becomes altered in its qualities, soon after the appearance of the inflamed areola; so that if it be taken for the purposes of inoculation after the twelfth day, it frequently fails to produce any effect whatever; and, in some cases, it suddenly excites a pustule, or ulceration; in others, an irregular vesicle; and, in others, erythemas. If taken when scabs are formed over the vesicle, (as in the case of pustules of small-pox,) the virus is occasionally so putrefactive and acrid, that it excites the same violent and fatal disease which arises from flight wounds, received in inflicted withal bodies.

"Again, the lymph, although taken from a perfect vesicle, on the sixth, seventh, or eighth day, may be so injured, before its application, by heat, exposure to the air, moisture, rank, and other causes, as to be rendered incapable of exciting the true disease.

"The most frequent cause of these imperfections, however, seems to be the presence of chronic cutaneous eruptions, or the concurrence of eruptive fevers, or even of other febrile diseases. The chronic cutaneous diseases, which sometimes impede the formation of the genuine vaccine vesicle, have been described by Dr. Jenner under the ordinary indefinite term herpes and tinea exsudativa. In the more accurate phræatology of Dr. Willan, they are herpes, (including the hingles and vesicular ring-worm,) psoriasis, and impetigo (the dry and humid tetter); the lechen, and most frequently the varieties of porridio, comprising the contagious eruptions denominated by authors *sycula lacteal, areata, acaules, and favo.* Dr. Willan thinks that the itch and prurigo likewise have the same influence.

"Of the interference of eruptive fevers, measles, scarlet fever, and chicken-pox, with the progress of the vaccine vesicle, when it has perforated, numerous instances have been recorded. The supposition of its progress, indeed, would be expected, under such circumstances, from the known facts respecting the reciprocal action of these contagious fevers on each other. But the action of the vaccine virus is not only suspended by these fevers, so that the vesicle is very slow in its progress, and the areola not formed till after the fourteenth day, or later, and sometimes not at all; but it is occasionally rendered altogether inefficient. Even typhous fever, and the influenza, have been observed to produce a similar interruption in the progress of vaccination.

"Finally, the vesicle without an areola, takes place if the person inoculated have previously received the infection of small-pox, or if he be affected with some other contagious disease during the progress of vaccination.

"Other irregularities may probably have occurred. At all events, though the constitution is sometimes fully secured from the infection of small-pox, even by the irregular vesicles; yet as it is more commonly but imperfectly guarded by such vesicles, the propriety of Dr. Jenner's caution is obvious, that when a deviation arises of whatever kind it may be, common prudence points out the necessity of re-inoculation." See Bateman's Synopsis of Cutaneous Diseases, p. 219—221. edit. 3.

The Methods of taking Vaccine Lymph for Vaccination.—The lymph of a regular vesicle is efficacious from the time it is secreted, till the areola begins to spread. It may, therefore, commonly be taken till the ninth day; but not after the areola is fully formed.

The lymph is to be taken by small superficial punctures made in the vesicle, with the point of a lancet introduced horizontally. Time should be allowed for the liquid to exude, which will form small pelliculid drops. When requisite, a very slight preflure may be cautiously applied with the flat surface of the lancet. Great delicacy is requisite in this operation; for if the vesicle be rudely treated, or too much opened, inflammation and ulceration may ensue.

Lymph intended to be used immediately, or in a few days, may be received on a lancet; but this is an improper instrument for preserving it longer; for the lymph soon rufts the lancet, and it is then liable to be infectious, or injurious. Quills and tooth-picks succeed; but small bits of
of ivory, shaped like the tooth of a comb, and properly pointed, are the most convenient instruments; and to render them more certain, they should be charged repeatedly.

In order to preserve lymph for a long period, the best method is by two bits of square glass. The lymph is to be received on the centre of one of them, by applying it to a punctured vessel. When fully charged and dry, it is to be covered with another bit of glass of the same size, and wrapped up in paper or in gold-beater's skin.

In whichever way the lymph is taken, it should be allowed to dry without heat, in the shade, and be kept in a dry and cool place. When inclosed in a letter, if great care is not taken, it may be injured by the heat of the melted wax in sealing the packet.

The Mode of Vaccinating.—Liquid lymph is better than dry, because it seldom fails, and the operation is more lightly and quickly performed. Therefore in every infusion, where it is practicable, the patient from whom the lymph is to be taken should be present, and the lymph should be transferred immediately from him to the person who is to be inoculated.

Vaccination is generally performed in the arm, near the infection of the deltoid muscle; but in order to hide the fear, and in adults who are likely to use the arm much, it may be advisable to vaccinate the outside of the leg, a little above or below the knee.

The lancet being charged, the skin should be stretched, and a small superficial puncture made with the point of the lancet, held nearly in a horizontal direction.

The lancet should be dipped in water and wiped after each operation, even when several successive inoculations are to be performed.

Dry lymph on glass may be moistened with a very little cold, or tepid water, on a point of a lancet, allowing it some time to diffuse, and blending it by a little friction with the lancet. It must not be much diluted, but ought to have a thin consistence; it is to be infected in the same manner as the recent fluid.

When quills, ivory lancets, or tooth-picks charged with dry lymph are used, the lymph should not be diluted, but a puncture having been first made with a common lancet, the point of the instrument is to be infected, and held in the puncture half a minute or more, that the lymph may gradually diffuse and remain in the wound. If the part of the instrument which is charged be afterwards wiped repeatedly upon the edges of the puncture, it will tend still farther to ensure success.

Vaccinated patients must be cautioned not to wear tight breeches, nor to injure the vehicle by prepressure, friction, or any other violence, lest inflammation or ulceration should ensue.

One perfect vaccine vehicle is sufficient; but for various reasons it may often be prudent to make two or three punctures, especially when the danger of receiving the small-pox is imminent, the lymph dry, or the patient's resistance deficient. Bifides, greater security is obtained against a chance of failure from the derangement or destruction of one vehicle by accidental injury, or by the taking of matter for vaccination. When two punctures are to be made in one limb, they should be at least two inches asunder, on account of the irritation they may occasion. And one of them should be always permitted to go through its course undisturbed. Lancets for vaccination should be kept clean and bright.

Constitutional Symptoms.—Constitutional symptoms sometimes occur after every period, but more commonly from the seventh to the eleventh day. Thrice are drownees, rellasses, a chilliness succeeded by heat, thirst, head-ache, and other marks of febrile affection. Now and then fecknels or vomiting takes places, especially in infants.

The constitutional symptoms are in general light and transient, and such as require no remedy.

In a great proportion of cases, there is no perceptible indisposition; nevertheless, the person vaccinated is not the less secure from the future infection of the small-pox, provided the progress of the vehicle has been regular and complete.

Care should be taken not to confound the symptoms of other diseases with those produced by vaccine inoculation.

Medical Treatment.—In general, no medicine is required in this mild affection; but if the symptoms happen to run a little higher than usual, the same remedies are to be applied, as if they proceeded from any other cause.

No preparatory medicines are necessary before vaccinating, and commonly no cathartics need be given afterwards.

Should the local inflammation exceed the usual bounds, which rarely happens, unless from tight sleeves, pre-pressure, or friction, it may soon be checked by the frequent application of compreßes of linen dipped in water, in aqua lithergyri acetai compota, or in a solution of one drachm of cerussa aceta in a pint of water. These are to be applied cold.

If the scab be rubbed off prematurely, and ulceration take place, cooling and astringent applications may be used; such as a drop of aqua lithergyri acetai, which should be allowed to dry on the part, and then be covered with compreßes dipped in water, or in either of the preparations of lead above-mentioned, and frequently renewed.

When the ulceration is deep or extensive, a poultice either of bread and milk, or of bread with any of the preparations of lead, may be applied, as the case seems to require. They must never be applied till they are nearly or quite cold.

In such foul and oblitinate fores as resile the foregoing applications, the unguentum hydrargyri nitrat., mixed with an equal quantity of unguentum cerae, or other similar applications, may sometimes be resorted to with advantage. And at other times, these fores may be healed with the unguentum ceruöse acetae, or the mildew applications.

The irregular vehicles and pustules are frequently followed by ulceration at an early period, and this ulceration is to be treated in the same manner, as if it proceeded from the regular vehicle.

When the patient has been previously exposed to the infection of small-pox, this disease will be either supereroded or not, according to the time which may have elapsed before vaccination.

Observations on the occasional Infficacy of Vaccination.—When the vaccine vehicle parfisons the above-described characters, and passes through the regular gradations, whether accompanied with any perceptible disorder of the constitution or not, it effectually and permanently secures the individual from the danger, and almost universally from the contagion of the small-pox.

It is now nearly twenty years since the first promulgation of Dr. Jenner's discovery; and yet the truth of the preceding observation remains unimpeached. As a well-informed physician has remarked, the very exceptions to this statement may be found, without a solicitation, to corroborate it. For, in the very small number of cases, (such as that of the son of Earl Grosvenor), where an extensive eruption of small-pox has occurred subsequent to vaccination, the controlling influence of the cow-pox has been manifestly and strikingly manifested, by the sudden interruption of the small-pox in the middle of its course, and the rapid convalescence of the patient. See Bateman's Synopsis, p. 216.
VACCINATION.

With very few exceptions, indeed, persons who have undergone both the local and constitutional affection of cow-pox, are thereby rendered unsusceptible of small-pox.

It is not meant to assert, however, as has been too generally imagined, that every person who has been inoculated for the cow-pox, is rendered secure against the contagion of small-pox. As Mr. Bryce has ably explained, there are many circumstances, besides the mere inoculation, absolutely necessary to be ascertained, before this security can be guaranteed.

Again, says Mr. Bryce, it is well known, that a person having undergone the small-pox is not absolutely secure from a future attack of the same malady, as well authenticated instances are recorded, where the same person has undergone this disease a second time, and these attacks were neither of them local, but very certainly general constitutional affections. See the case of Mr. R. Langford, recorded in the fourth volume of the Memoirs of the Medical Society of London. This gentleman was infected with the small-pox at a very early period of life, and was much marked from the severity of the disease. Many years afterwards, he was again infected with the small-pox, which was of the common kind, and proved fatal on the twenty-first day from the attack. See also Dr. Woodville's History Of Inoculation, p. 217; Mr. Ring's Answer to Dr. Mofley, where many such cases are recorded; and the case of Lord Willemath's child, published in the Medical and Physical Journal, vol. xiv. p. 256.

Now, as Mr. Bryce remarks, with regard to the cow-pox, it may also happen, that a person who has undergone that affection, may yet be afterwards affected with small-pox; but, as is well known in the former case relative to small-pox, so also in the latter relative to cow-pox, the instances of the second attack from small-pox, or of the failure of the cow-pox to prevent the small-pox, are so very rare, as by no means to affect the general established rule; that persons who have once undergone the small-pox, or the cow-pox, as a constitutional affection, may that securily be reckoned secure against all future attacks of various contagion. (See Bryce's Practical Observations on the Inoculation of Cow-pox.) Besides the examples of the recurrence of small-pox a second time in the same individual, to be found in the publications already specified, additional instances are recorded by Dr. Jenner himself, Mr. Bryce, and in the Reports of the National Vaccine Establishment.

We shall here present the reader with the history of two remarkable cases published by this last institution; the one illustrating the occurrence of small-pox a second time in the same person, the other exemplifying the equally uncommon circumstance of an individual who had perfectly undergone vaccination, being afterwards affected with the small-pox.

Dr. Bree was called to visit Miss Sarah Booth, of Covent Garden theatre, on Monday, June 25th, 1811. She was said to be ill with the small-pox, and the following circumstances were reported by the mother and sisters. Miss Booth was then eighteen years of age. She had been inoculated for the small-pox at five years of age, and had been affected with the usual degree of fever. The arm had been violently inflamed, and an eruption of small-pox pustules had appeared round the inoculated part, from which matter had been taken by Mr. Kennedy, the surgeon who attended her. Mr. Kennedy expressed himself satisfied that Miss Booth had suffered regularly through the disease.

The usual scar of small-pox inoculation was perfectly evident on the arm.

On Thursday, June 20th, 1811, Miss Booth was seized with fever, distinguished by vomiting, violent head-ache, and pains in the back and loins.

The symptoms continued till Saturday, June 22d, in the evening of which day, some pustules came out on the forehead and scalp.

Sunday, June 23d, a more complete eruption appeared on the face and neck, and she was relieved from the violence of the fever. The vomiting however continued, the throat became very sore, and a salivation began.

Monday, June 24th, the eruption extended itself on the body, the fever was still more abated, but the salivation, forebears of the throat, and vomiting, were urgent symptoms.

Tuesday, June 25th, the fourth day of the eruption, the salivation and retching continued, with forebears of the throat.

Wednesday, June 26th, fifth day of the eruption, pustules were noticed on the lower extremities, those on the face advanced, the eyes were swelled; and the number of pustules on the head and face was about two dozen.

Thursday, June 27th, sixth day of the eruption, the pustules on the face began to turn. She still suffered from sore throat and salivation.

Friday, June 28th, the pustules on the face turned, those on the lower extremities were few in number but well filled, and not yet changed.

Saturday, June 29th, eighth day of the eruption, the only complained of sickness. After this day, the pustules turned and dried on the lower extremities, and no complaint remained.

Dr. Bree considered this as a mild case of diffinent small-pox.

On Sunday, May 26th, 1811, the Hon. Robert Grovenor, who was recovering from the hooping-cough, became much indisposed and threw up his dinner. Fever followed, and he complained moit particularly of exacerbating pain in his back.

He dwelt on this symptom until Thursday, when he became delirious, and there were observed on his face about twenty pustules.

He had been vaccinated by Dr. Jenner, in his infancy, about ten years ago, and the mark left in his arm indicated a perfect disease.

On Friday morning, the eruption had not increased materially in point of number, but the appearance of the spots and the previous symptoms, suggested strongly a suspicion that the diforder was the small-pox.

Sir H. Halford had occasion to go to Windsor in the afternoon of Friday, and did not see Mr. Robert Grovenor until the Monday following (June 2d,) but he learned from Sir W. Farquhar, who attended him most carefully during Sir Henry's absence, and subsequebtly, that the eruption had increafed prodigiously in the course of Friday; that on the evening of that day, Mr. Robert Grovenor began to make bloody water, and that he continued to do so until Monday morning.

On the tenth day of the disease, the pustules began to dry upon the face, which was swollen to a considerable degree, but not to the extent of closing his eyes, and was attended by a salivation which lasted several days. Petechiae had occurred in the intertices of several of the spots, particularly on the limbs, and there was that particular smell from the whole frame which is remarkable in bad cases of contagious small-pox.

It was obvious that the first symptoms of which Mr. Grovenor complained, were such as indicated a violent difeafe about to follow, and Sir Henry concedes that he entertained a moft unfavourable opinion of the issue of such a malady, when it was fully formed; having never seen an
VACCINATION.

influence of recovery under so heavy an eruption attended by such circumstances. It seemed, however, that the latter stages of the disease were passed through more rapidly in this case than usual, and it may be a question whether this extraordinary circumstance, as well as the ultimate recovery of Mr. Grofvenor, were not influenced by previous vaccination.

The Board of the National Vaccine Establishment are of opinion, that the case of the Hon. Robert Grofvenor was a case of confluent small-pox: that the attack and progress of the disorder were attended by symptoms which almost invariably announce a fatal termination. But they observe, that the swelling of the face, which is generally so excessive as to close the eyes, and is considered as a favourable symptom, was lighter than usual; that on the tenth day the pustules began to dry upon the face, and that from that time the disease passed with unusual rapidity through the period when life is generally esteemed to be in the greatest hazard.

Those who are acquainted with the nature of the confluent small-pox, are aware that this peculiarity cannot be attributed to the effect of medical treatment.

In most cases of small-pox which have succeeded to vaccination, the pustules have been observed to dry more rapidly, and the disorder has concluded at an earlier period than usual.

If allowance be made for the relative periods in which the confluent and distinct small-pox complete their course, the rapid progress towards recovery through the latter stage of confluent small-pox, as exhibited in the case of Mr. Grofvenor, may be compared with the rapid desiccation of the pustules in the distinct and peculiarly mild form of the disorder which is considered as small-pox modified by vaccination. Both forms of the disorder proceed in the usual course, the one attended with violent, the other with mild symptoms, till they arrive near to the height, when they appear to receive a check, and the recovery is unusually rapid.

From this correspondence of circumstances, the Board are induced to infer, that in the case of Mr. Grofvenor, which has been more violent than any yet submitted to them, the progress of the disease, through its latter stage, and the consequent abatement of symptoms, were influenced by an anti-variolous effect produced upon the constitution by the vaccine process.

The occurrence of small-pox after vaccination, has been foreseen and pointed out in the report on vaccination made to parliament, by the College of Physicians, in the year 1807, to which the Board are defirous of calling the attention of the public; in which it is stated, that "The security derived from vaccination against the small-pox, if not absolutely perfect, is as nearly so as can perhaps be expected from any human discovery; for amongst several hundred thousand cafes, with the results of which the College have been made acquainted, the number of alleged failures has been surprisingly small; so much so, as to form certainly no reasonable objection to the general adoption of vaccination; for it appears that there are not nearly so many failures in a given number of vaccinated persons, as there are deaths in an equal number of persons inoculated for the small-pox. Nothing can more clearly demonstrate the superiority of vaccination over the inoculation of the small-pox than this consideration; and it is a most important fact, which has been confirmed in the course of this enquiry, that in almost every cafe in which the small-pox has succeded vaccination, whether by inoculation, or by casual infection, the disease has varied much from its ordinary course; it has neither been the same in violence, nor in the duration of its symptoms; but has, with very few exceptions, been remarkably mild, as if the small-pox had been deprived, by the previous vaccine disease, of its usual malignity." Report of the College of Physicians, p. 4.

The peculiarities of certain convulsions with regard to eruptive fevers, form a curious subject of medical history. Some individuals have been more than once affected with scarlet fever and measles; others have been through life exposed to the contagion of these diseases without effect; many have resisted the inoculation and contagion of small-pox for several years, and have afterwards become susceptible of the disorder, and some have been twice affected with small-pox.

Among such infinite varieties of temperament, it will not appear extraordinary, that vaccination, though so generally useful, should sometimes fail of rendering the human constitution unussceptible of small-pox; especially since it has been found that in several instances small-pox has occurred to individuals over whom the small-pox inoculation had appeared to have produced its full influence. Three instances of this kind have taken place within the last month; and, in another instance, the natural small-pox has occurred a second time. See Report of the National Vaccine Establishment, July 1811.

It has been imagined by some, that although the human constitution is apparently shielded from the action of small-pox by having undergone the cow-pox, yet that this security may not be permanent; but that, at the end of a certain period of time, the person will again become susceptible of small-pox. This objection, however, must now have little weight; for Dr. Jenner himself inoculated with the virus of small-pox, persons who had been affected with the cow-pox twenty-five, twenty-seven, thirty-one, and thirty-three years before; but who had never been infected with the small-pox, and these he found completely refitted this disease.

For further evidence and reasoning on this point, see Fer- mor's Reflections on the Cow-pox; Edin. Rev. No. XVII; and Bryce's Practical Obs. on the Cow-pox.

Experience has proved that, in certain instances, the cow-pox virus has merely a local action, and such cases have been mistaken for the regular constitutional affection; a thing very likely to happen, when it is remembered that the general ailment of the system is seldom marked by any very strong symptoms; and that, in the cases alluded to, the local appearances would pursue a regular progress. Yet, in these circumstances, the patient is left unprotected from an attack of small-pox. As Mr. Bryce has pointed out, therefore, a certain set of the constitution being really affected in every inoculation of cow-pox must be an important differentia. Indeed, until there be demonstrated and generally known some unequivocal mark of a constitutional affection, which does constantly occur during the course of cow-pox, when effectual, and which may be as easily distinguished as the fever and eruption consequent to the inoculation for small-pox, this new inoculation ought never to be performed, except by persons well acquainted with every appearance of the ailment. For, as much as it is more difficult to distinguish between the cow-pox and some other affections, and also clearly to ascertain the presence of a constitutional affection, than to form a similar judgment in the inoculated small-pox, the more does the cow-pox inoculation require attention to every symptom which may occur during its progress, in order that mankind may reap every advantage which has been promised from the general adoption of cow-pox as a preventive of small-pox.

Mr. Bryce has endeavored to discover a criterion of the patient...
patient being constitutionally affected with the cow-pox, and
the following observations upon this important subject merit
particular attention. "I recollected (says he) some experi-
ments which had been made with regard to the inoculation of
small-pox. It was found, that if the same person was ino-
culated every day, until the fever induced by the first ino-
culation supervened, all the other punctures quickly advanced
in their progress; and that, in the course of a day from the
time the fever or general affection began, even that puncture
which had been last made, perhaps only twenty-four hours be-
fore, equalled in maturity the one first made, perhaps eight
or nine days before, and from which the fever had arisen.

"In this case, it appears to me evident, and I think it must
be admitted by every person, that even had no other pustules
appeared on the body but those occasioned by the repeated
inoculations; nay, had there even been no fever observed in
consequence of the inoculation; yet as the pustule occa-
ioned by the last puncture had been suddenly accelerated in
its progress to maturation, at the time the general or con-
stitutional affection should have appeared; this alone was a su-
fficient proof of the presence of the various action in the
syringe.

"Judging again from analogy, I expected that the same
thing, which thus happened in the small-pox inoculation,
might also take place in that for the cow-pox; and the unex-
pected appearance of one or two vehicles upon children that
I had inoculated, which vehicles were quite characteristic of
the ailment, and the appearance of which I could only ac-
count for from a second and accidental inoculation during
the course of the disease, strengthened my hopes. And, cer-
cainly, if we find in cow-pox, where the inflamed and
hard erupcion does not take place, a leaf in the regular
course of that affection, until the end of the seventh, or
beginning of the eighth day from inoculation, that a se-
cond inoculation, performed, for example, at the end of the
fifth, or beginning of the sixth day, is so much accelerated
in its progress, about the time the general affection of the
system usually takes place, as to have an areola formed within
a few hours, or very shortly after the first, and that this
areola increases with the first, and again fades at nearly the
same time, we must be struck with the similarity, and be
forcibly led to draw the same conclusions in this case as in the
former, respecting the small-pox, viz. that although the
inoculated affection had appeared very slight, and no fever
had been observed, yet that a certain action had been ex-
cited in the constitution. That this was the true constitu-
tional affection of cow-pox, may be judged by the acceler-
ation of the second vehicle to a state of maturity five days be-
fore this could have happened, had there been no concomit-
ant general action, or change in the system."

Mr. Bryce next details a series of experiments, which
tend to prove, that if, during the regular progress of cow-
pox, a second inoculation be performed a certain number of
days after the first, the affection produced by this second
inoculation will be accelerated in its progress so as to arrive
at maturity, and again fade at nearly the same time as the
affection arising from the first inoculation; and that this
will take place, although the constitutional affection be so
light as otherwise to pass unnoticed.

From several examples related by Mr. Bryce, and a great
many other cases, in which the second inoculation was per-
formed at different periods of the primary affection, it is
concluded, that the most proper time for performing the
second inoculation, is about the end of the fifth, or begin-
ning of the sixth day, from the first inoculation; reckoning
each day to confit of twenty-four hours. Thus, if the first
inoculation be performed on Monday, at the same
hour, at which time the fifth day is considered to be finished,
and the sixth day to begin. If the second inoculation be
delayed beyond the fifth day, the affection produced by it
will be very indistinct, and of short duration; and if per-
formed at an earlier period than the fifth day, the contrast
between the progress of the two affections, with regard to
duration, will not be so great as may be thought neces-
Sary.

"These observations, however, (says Mr. Bryce,) are ap-
licable to those cafes only, in which the first inoculation
advances by a perfectly regular course, and in which the
areola begins to form about the end of the seventh, or begin-
ing of the eighth day from inoculation; and I think it
probable that the second inoculation is from certain causes accelerated or re-
tarded one or two days, as frequently happens, then the
second inoculation should be performed at a more early or
late period accordingly.

"In short, my observations on this point lead me to con-
clude, that in order to obtain the proposed criterion in the
greatest perfection, the second inoculation should be per-
formed between thirty-six and forty-eight hours before the
areola of the first inoculation begins to appear. This is
necessary in order that the secondary affection may have
proceeded some length, and that a small vehicle, containing
virus, may have been formed by it, before the constitutional
action from the first inoculation begins, otherwise no areola,
but merely a slight degree of hardness will take place from
the second puncture.

"As, on the one hand, the acceleration of the second
inoculation in the manner above-mentioned, is to be re-
garded as a certain mark of a constitutional affection in
cow-pox, fo, on the other, if it shall be found that no such
acceleration takes place, but that the second inoculation
proceeds by a slow progress through all the stages, and has
the duration of a primary affection, it is to be concluded
that no constitutional action has taken place from the first
infestation of the virus; and when this is the case, the second
inoculation must be regarded as a primary affection, and a
third puncture be made according to the plan laid down for
conducting the second inoculation; and thus we may go on
until the proper test be obtained, or until we be satisfied
that the constitution completely refits the affection of cow-
pox." See Bryce's Practical Observations on the Inocula-
tion of Cow-pox, edit. 2.

Many other particulars relating to the subject of vaccina-
 tion will be found in another place (see Cow-pox), and we
shall therefore merely add, that the new practice is on every
account deserving of the confidence and encouragement of
the public. The cow-pox is greatly milder than the small-
pox, even under the most approved mode of treatment;
being never attended with danger, seldom with sicknesses,
and never producing pustules generally over the body, nor
indeed any disfiguration of the skin, except at the part
where the virus has been truly infected by the inoculator.
The small-pox is one of the most contagious diseases to
which the human race is subject; and, when propagated in
this way, it is one of the most fatal. On the other hand,
the cow-pox is not at all contagious, and can only be com-
municated by the injection of the vaccine virus to the
part affected, as happens in the accidental inoculation of the
hands of milkers, and the ordinary practice of vaccination.

Many hundreds of thousands have now been vaccinated in
these kingdoms, and yet there is not on record a single une-
quivocal instance of the cow-pox having proved fatal.
Corresponding agreeable accounts are also received from
every part of the civilized world. The weight which this
consideration ought to have may be well conceived, when it
VACCINIUM.

is remembered, that in Great Britain and Ireland alone, the yearly mortality arising from the small-pox used to be estimated at about 45,000 perons. In the Russian empire, and other cold countries, the ravages of the small-pox were far more dreadful, and this contagion sometimes broke out in such regions with a degree of fury far exceeding any thing ever heard of the plague itself. See INOCULATION.

VACCINIUM, the new scientific name of the cow-pox, and which is now adopted by all the latest and best medical writers. See COW-POX, and VACCINATION.

VACCINIUM, in Botany, an ancient Latin name, whether of a flower or a berry has always been a point in dispute among critics, as well as the etymology of the word. Some conceive it to have been derived from the Greek λαγισμος, and therefore to be either precifically synonymous with the Latin Hyacinthus, or at least to belong to something agreeing with that plant in colour. The line of Virgil,

"Alba ligustra cadunt, vaccinia nigra luguntur," has afforded scope for the commentators, being equally obscure, whether we suppose ligustra to mean the flowers of the privet, and vaccinia its black berries, (which, by the bye, are not gathered by any body,) or whether, as is the most general opinion, the latter word may express our Bilberry, or any other black or dark berry in general use. We have already observed, in its proper place, that our Privet is not the original Ligustrum; see that fact. Linnaeus however declares, very reasonably, that no future contentions or discoveries of the learned shall unfetle his name of Vaccinium, as applied to the Bilberry or Whortleberry tribe, for which this generic appellation is now universally adopted.

Eries, Jull.

Gen. Ch. Cal. Perianth superior, of one leaf, small, permanent. Cor. of one petal, bell-shaped, more or less deeply four-leaf; the segments revolute. Stam. Filaments eight, simple, inserted into the receptacle; anthers two-horned, burbling at the funnits, and sometimes furnished at the back with two spreading spurs, or bristles. Pist. Gern ridnith, inferior; Ryle simple, longer than the filaments; stigma obtuse. Peric. in berry globose, depressed at the top, of four seeds, few, small. Eff. Ch. Corolla of one petal. Stamens inserted into the receptacle. Anthers with two terminal pores. Berry inferior, of four cells, with several seeds.

Obf. Linnaeus remarks, that "one fifth is often added to every part of the fruitification;" hence Mr. Pursh has removed Vaccinium to the clas Decandria. The Swedish naturalist also mentions, that "the calyx, four-leaf in many of the species, is entire in V. Myrtillus; and that almost the whole of the fierce corolla of V. Oxyccous is rolled back to its base." The latter character caused Tournefort, who relied so much on the corolla, to separate Oxyccous as a genus, in which Pursh, with one or two other botanists, have followed him. But Tournefort erroneously supposed this flower to have four distinct petals, a mistake corrected by Linnaeus; see Fl. Linn. n. 145, where sufficient reasons appear for considering the plant as a Vaccinium. The character of the tubular deeply divided anthers in Oxyccous, superadded by Mr. Pursh, tends only to deceive, being found in several indubitable species of Vaccinium.

The genus before us, mostly confined to Europe and North America, is peculiarly abundant in the latter country. It is very remarkable that, as no Erica occurs in America, so no Vaccinium has been found at the Cape of Good Hope. These genera, similar in many of their flowers, differ no less widely in the situation of their germen, and texture of their fruits, than in the infection and habit of their foliage, which in Vaccinium is scattered, dilated, generally membranous and deciduous; always indeed simple and undivided; but totally unlike the narrow, whorled, evergreen leaves of Erica. The flowers in Vaccinium are copious, fleshed, either solitary, simply racemose, or tufted, drooping, inodoruous, generally very elegant, tinted with various shades of red or pink, never blue, scarcely yellowish. Berries black, purple, blue, or red, generally eatable, though not pleasant, nor always wholesome, in a crude state. Stem hirsute, bushy, of humble stature. Stipulas none.

The species of Vaccinium were ill understood by Linnaeus, but we hope to trace the origin of many of his errors, which have never been cleared up, and have led all following authors astray. Murray defines but fifteen species in the fourteenth edition of Syll. V. Wildenow has twenty-seven, of which five are European, three natives of Japan, one of Otaheite, one of Jamaica, the rest North American. Pursh has twenty-five species of Vaccinium, besides three of Oxycoccus, from North America only. In reviewing the whole of the genus, we find something to add, though we have many species that are dubious. We are obliged to follow the distribution of Linnaeus, by which the evergreen species are separated from those which are deciduous, though some uncertainty must always attend that character, respecting species known from dried specimens only.

Sec. 1. Leaves deciduous.

1. V. Myrtillus. Common Bilberry, or Bleaberry. Linn. Sp. Pl. 458. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 456. Fl. Dan. t. 974. (Vaccinia nigra; Ger. Em. 1415. Myrtillus; Math. Valgr. v. 1. 210. Camer. Epit. 153.)—Stalks solitary, fingle-flowered. Leaves deciduous, ferrated, ovate, smooth. Stem acutely angular. Calyx finely divided. Native of heaths, stony moors, and mountainous woods, throughout most parts of Europe, especially the more northern, flowering in May. Dr. Sibthorpe gathered it also on the Bithynian Olympus. The fruit is woody. Stem from six to eight inches to two feet high, erect, bushy, smooth; the young green branches leafy, a little zigzag, furnished with very acute dilated angles. Leaves about an inch long, on short footstalls, pubescent, veiny, rather acute, copiously ferrated; paler beneath. Flowers pendulous, on simple, naked, smooth, axillary stalks. Calyx dilated, angular, seldom so much lobed as in Engl. Bot. Corolla globose, generally five-leaf, of a very delicate waxly pink hue. Anthers horned. Germen glaucous. Berry the size of a currant, bluish-black, acid, eaten in tarts, or with cream, in the north and west of England. In the eastern counties this plant is not plentiful. Its fruit is sometimes sent into Norfolk from Devonshire. Mr. Menzies brought, from the west coast of North America, what we can scarcely make more than a gigantic variety of this species, seven or eight feet high, larger in every part, with less distinctly ferrated leaves.

2. V. ovulifolium. Oval-leaved Bilberry.—Stalks solitary, fingle-flowered. Leaves deciduous, elliptical, oblong, pointed, entire, smooth, strongly veined beneath. Stem angular. Calyx finely divided.—Brought by Mr. Menzies from the west coast of North America. A forb ten or twelve feet high, whose smooth branches are less acutely angular than in the foregoing, and whose leaves are very essentially differing.
being either perfectly elliptical, or slightly ovate, blunt, and quite entire, about an inch and a half long, copiously reticulated with fine veins, quite smooth on both sides; rather paler beneath. Flowers solitary at the base of each tuft of budding leaves, drooping, each accompanied, at the base of its stalk, by a large ovate, acute, coloured bractea. The flowers seem to agree with those of V. Myrtillus in size, colour, and structure, except that the corolla is more ovate. The berries are black, crowned with the cup-shaped, slightly four-lobed, calyx.

3. V. parviflorum. Small-flowered Red Bilberry.—Stalks solitary, single-flowered. Leaves deciduous, elliptical, ob- two, pointed, entire, smooth; glaucous, and slightly veiny, beneath. Stem acutely angular. Calyx scarcely divided. Stalk of the fruit club-shaped.—Gathered by Mr. Menzies on the west coast of North America. The shrubby folk is eight or ten feet high, with smooth zigzag branches, whose angles are as much dilated and prominent as in our first species. The leaves most agree with those of **ovatifolium** in shape, but are at their full growth scarcely a quarter fo long, and each tipped with a small point; their under side rather glaucous, with less copious, and far less prominent, veiny reticulations. We have seen no flowers. The berries are red and make excellent tarts. They appear to be smaller than the half, crowned with a similar calyx, but their stalk is shorter, measuring scarcely half an inch, more drooping, and very remarkably swelling upward, so as to be quite club-shaped, contracted at the summit, of which the foregoing flesws but flight traces. There is no doubt of these two species being very different from each other, as well as from all hitherto described by authors.

5. V. birtum. Hairy Japan Whortle-berry. Thunb. Jap. 155. Wild. n. 3.—Stalks solitary, single-flowered. Leaves deciduous, ovate, ferrated, hairy all over as well as the young branches.—Gathered on hills between Misco and Jedo in Japan, by professor Thunberg, one of whose specimens is before us. A taller shrub than our **Myrtillus**, flowering in April. The branches are round. Leaves like that species in size and shape, but covered with soft hairs; their under side rather pale. **Flowers** drooping, on very short stalks.

6. V. pulgigum. Great Bilberry. Linn. Sp. Pl. 459. Wild. n. 5. Fl. Brit. n. 2. Engl. Bot. t. 581. Fl. Dan. t. 231. Pursh n. 15. (Vitis idea magna quibusdum, five Myrtillus grandis; Bauh. Hist. v. 1. 518. Rauy Syn. 457. V. idea folis subrotundis major; Ger. Em. 1416.)—Stalks somewhat aggregate, single-flowered. Leaves deciduous, ovate, entire, smooth. Branches round.—Native of marily mountainous heaths, and alpine bogs, in Sweden, Germany, Switzerland, Savoy, Scotland, and the north of England; as well as in the more northern parts of America, and on its west coast; flowering in April or May, and ripening the berries, which are elastic, but not either very grateful or wholesome, in August. Taller than the Common Bilberry, and of a more glaucous hue. Leaves smooth and even above; veiny and glaucous at the back; quite entire, by which this species is readily distin-

VACCINIUM.

guished from all that in other respects bear any resemblance to it. **Flowers** drooping, flesh-coloured, mostly four-cleft, with eight long-horned stamens. **Calyx** short and blunt. **Berry** large, juicy, black, with a glaucous hue. **Seeds** finely flatted. A variety with slightly pointed leaves, was published by an apothecary at Berne, in 1787, as *V. muscronata*, an imaginary species, of which we shall speak at the end of our eighth.

7. V. calycinum. Large-cupped Whortle-berry.—Stalks solitary, single-flowered. Leaves deciduous, ovate, ferrated, smooth, with downy ribs. Branches angular. Segments of the calyx deep, ovate.—Gathered by Mr. Menzies, in woods, upon lofty mountains, in the Sandwich islands. This appears to be of a much taller stature than the preceding. The leaves at the flowering feason are an inch and a quarter long, near an inch wide, plant, with fine, copious, pointed, incurved ferratures, and a small, blunt, terminal point; their under side pale. **Flowers** about the lower part of each young leafy branch, axillary, drooping, each on a simple, naked, slightly downy calyx, an inch long. **Calyx** in five, rather unequal, deep, ovate, entire, blutfith, smooth, finely reticulated segments, exceeding the germen in length. **Corolla** oblong, with five angles, enclosing the anthers and style. Of the fruit we have no knowledge.

8. V. flammeum. Green-wooded Whortle-berry. Linn. Sp. Pl. 498. Wild. n. 4. Ait. n. 5. Pursh n. 1. Andr. Repof. t. 263. (V. album; Pursh n. 2, excluding the synonym of Wildenow. Arbuscula americana baccifera, floribunda cornuta, &c.; Pl. Mag. 32. Phyt. t. 459. f. 3.—Clusters downy, with oval bracteeae as long as the flowers. Anthers twice as long as the spreading bell-shaped corolla. Leaves elliptical, acute, entire; glaucous and rather downy beneath.—Common in dry woods, from New England to Florida, flowering in May and June. The trunk is firm, about two feet high, with numerous green branches, downy when young. Leaves an inch and a half or two inches long at the flowering feason, on very short downy stalks. **Flowers** copious, white, with remarkably conspicuous, tawny, linear anthers, spurred near the base. **Corolla** broader than long. **Berries** greenish, or white, called Deer-berries. Analogy leads us to consider the influence of this species as racemose. Indeed the bractae, though resembling the leaves in every respect but size, are usually but one-fourth as large, and sometimes not a quarter of an inch in length. Mr. Pursh's album can fearrowly, by his definition or Andrew's figure, be marked even as a variety, though he says the flowers are larger, and berries more globose, than in the common *flammeum*. That his plant was not the Linnaean album, appears from the original specimen, sent by Kalm to Linnaeus, under the denomination of "3. **Vaccinium** with white berries," but which proves *Xylosteum ciliatum* 8, Pursh 161. No wonder that no subsequent investigator could ever ascertain *V. album*! We must notice another error of Linnaeus, to prevent mistake. He cites under *V. flammeum* the proper figure of Plukent, but with a wrong synonym or definition. Here also it falls to our lot to correct our great master respecting another of Kalm's plants, *V. muscronata*, which has ever remained as unintelligible as the album. His described specimen is certainly one of the *Meaphus* or *Pyrus* tribe, but not in a condition for us precisely to ascertain the species, nor can we refer it to any thing in Mr. Pursh's work.

9. V. arborum. Shining-leaved Tree Whortle-berry. Marth. in Michaux Borcal.-Amer. v. 1. 230. Pursh n. 5. (V. diffusum; Ait. n. 5. Wild. n. 8.)—Stalks axillary and solitary, or terminal and racemose, naked. Leaves ovate, acute, with flight glandular ferratures; polished above;
VACCINiUM.

above; rather downy beneath. Corolla bell-shaped, acute. Stamens the length of its tube. In dry woods, on the rocky banks of rivers, from North Carolina to Florida, flowering in May and June. A large fbrub, sometimes twenty feet high, very elegant. Flowers white, tinged with red, BDX. globular, black, almost dry, downy. Our numerous wld as well as cultivated specimens, compared with the Bankian herbarium, and answering to every particular of the published accounts of this plant, have no doubt of its identity, and therefore we do not repel to adopt Michaux's name, in preference to the older one, diff-fusum, the latter being founded in some mistake. The branches are round, downy when young. Leaves peculiarly shining, and strongly reticulated with veins. Flower-stalks an inch long, angular, marked with two or three glands; some of them auxiliary, solitary, from several of the lower leaves of each branch; others forming a nearly leafless clufier, at the end of the fame branch. In one instance we find two fuch clufiers, with a small leafy breace, or two in the middle. Notwithstanding a short lateral branch, whose leaves are fallen. This species, as Nature has drawn no precise line of demarcation between the racemoe and the solitary inflorescence of this genus, which in many species, by the ambiguous nature of their floral leaves, run into each other.

10. V. augiffifolium. Narrow-leaved Whortle-berry, or Bluet. Ait. n. 6. Wild. n. 9. (V. myrtilleoides; Michaux Boreol.-Amer. v. 1. 234. Purf. n. 16.)—Stalks scattered, mostly solitary, single-flowered, naked. Leaves lanceolate, nearly entire; downy at the ribs and margin. In Canada, about Hudson's Bay and Labrador, flowering in April and May. Berries large, bluefih-black, known by the name of Bluets. Purf. Michaux fays this species has the habit of V. Myrtillus; its leaves being membranous, of a narrow lanceolate form. We have seen no specimens. Dr. Solander's original name, in Hort. Kew. and Willdenow, appears preferable to that of Michaux adopted by Purf.

11. V. dumofum. Bufy Whortle-berry. Ait. n. 7. Purf. n. 4. Curt. Mag. t. 1166. Andr. Repof. t. 112. (V. brodofum; Michaux Boreol.-Amer. v. 1. 230. V. hirtelhum; Ait. n. 12, according to Purf. from a conparifon with the Bankian herbarium.)—Clufiers downy, with oval breaces; partial stalks with two lanceolate ones. Leaves obovate, pointed, entire, downy and vifcid. Germs hairy. Corolla bell-shaped, obtufe, longer than the ilamens.—In dry fandy woods, particularly pine forests, from New Jersey to Florida, flowering in June and July. A low bufy fbrub, with round branches. Leaves an inch and a half long, varying in breadth, reticulated with veins; paler beneath, but not at all glaucous; covered all over, especially when young, with short vifcid pubefeence, and glaucous dots, as are also the branches, flals, and breaces. Berries grow along the flowers, and leafy, like thofe of V. tla mineum, n. 8; but each partial flower-flalk bears also, about its middle, two smaller, lanceolate, sometimes coloured, partial breaces. The germs are particularly fhaggy. Segments of the calyx deep, ovate, fringed, co- coloured. Corolla white, tinged with pink, rather large. Berries black, globular. A comparifon of the two figures above cited will shew the ambiguous nature of the inflores- rence, and account for this species having been described twice in the accurate publication of Mr. Aiton.

15. V. foefatum; Ait. n. 8. Willd. n. 13. Purf. n. 11. (V. lormofum; Andr. Repof. t. 97.)

Flowering branches nearly leafless. Clufiers corymbofe, drooping. Breace membranous, shorter than the downy flower-flals. Leaves elliptical, acute, minutely ferrated, smooth, with downy ribs.—Native of swamps and wet woods, from Canada to Carolina and Georgia, flowering in May and June. A tall fbrub, sometimes seven or eight feet high, with numerous roughifh round branches; fome fhort and angular and downy when young. Leaves for the moft part round the flowers, an inch and a half or two ifches long, elliptic-oblong, acute at each end, various in breadth, veiny, but not ftrikingly reticulated; very minutely, more or less evidently, ferratet; tipped with a glandular point; smooth, except the rib and veins, which are finely hairy or downy, especially at an early period. Flowefflals fhort and broad, downy. Clufiers from branches of the preceding year, feldom accompanied with leaves, alternate, about an inch long, and rather compact, often corymbofe, of fix or eight drooping flowers, whose partial flals are fimply downy, with short curved hairs, and furred at the base with membranous, reddifh, smooth, fringed, decifedous breaces, varying in length and acutenefs, but mollifly much shorter than their correffponding flals. Segments of the calyx broad and shawf. Corolla white or reddifh, cylindrical, somewhat angular, contracted at the mouth, with five fhowy, spreading, marginal segments. Stamens ten, downy. Anthers within the corolla, having a double pouch at the base, but no fpur. Style foftimes, but not always, a little prominent. Berries black, infipid. Some apology may feem neceffary for our thus uniting four reputed fpecies, a measure of which Michaux firf, in part, fuggfed the propriety. With repect to the corymbifum and amanum, original fpecies of each, and the total want of any diftinctive character in authors, will abundantly justify us. The calyx fpreads equally in both. Indeed the former being always unknown, by name, in our gardens, and its specific character in Linnaeus being infufficient, if not incorrect, that fpecies could be aecertained by his herbarium only, which in this instance was neglected, and the fame plant appeared in the firft edition of Hort. Kew. under the name of amanum, acquired in England. It had here once been called elevatum, as appears by a fpecimen given to the younger Linnaeus. Some gardeners subfequently transferred flaminicum the name of amanum, and hence perhaps when the latter appeared after from America, it received the new appellations of virgatum and fusfeatum, perpetuated likewife in Hort. Kew., between the original specific characters of which there can be little discovered that is effential. In Mr. Andrews's plate of virgatum indeed the clufiers are accompanied by leaves, of which we have been no example in corymbifum, and the flowers are smaller than usual in this latter; but Mr. Purf. under the name of amanum, allows that it "has a number of varieties in size, shape, and colour." The elegant fusfeatum, as figured by Mr. Andrews, evidently betrays a close affinity

10
to *cosymphum*, colour being avowedly of no importance, and the erect *calyx* we have good reason to mistrust. Having formed our opinion from the beet materials in our power, we leave its refutation or confirmation to those who may have opportunities of future inquiry, without any intentional disrespect to the great authorities from which we differ.

14. *V. breitatum*. Bracteate Japan Whortle-berry. Thunb. Jap. 156. Willd. n. 11. — Clusters axillary, longer than the smooth, acute, ferrated leaves. Bracteas lanceolate, ferrated ; partial flasks with two smallerawl-shaped ones. — Gathered by Thunberg in the island of Niphon, Japan, flowering in June. The branches are always smooth, leafy, slightly angular when young. *Leaves* eliptic-lanceolate, acute at each end, an inch and a half long, on short flanks, sharply but not deeply ferrated, very smooth on both sides; paler, and moist reticulated, beneath. We should suspect them to be evergreen, as they accompany the flowers, on what seem to be last year's shoots; but having no particular information, we, like Willdenow, place this species among those to which it appears to be naturally related. *Clufters* two or three inches long, axillary, solitary, simple, slender, many-flowered, very smooth. *Partial flasks* short, drooping, turned all one way, each having at its base a lanceolate, acute, smooth *bractea*, mostly twice its own length, and about the middle two others of a very small size. Segments of the *calyx* short, acute, spreading. Corolla cylindrical, white. Nothing is known of the fruit. The Japanese call this plant *Kj Fuji*.

15. *V. cilatum*. Hairy-ribbed Japan Whortle-berry. Thunb. Jap. 156. Willd. n. 12. — Clusters axillary, longer than the ovate, brilly, nearly entire leaves. Bracteas lanceolate, smooth. — Native of Japan, where it is called *Sasjebu*. The stem is smooth, ash-coloured, with upright villous branches. *Leaves* ovate, acute, unequal, from one to two inches long, ribbed; the ribs bifid all over. Flowers red, turned one way, in terminal, solitary, bracteate *clufters*, as long as the finger. Bracteas about one-third of an inch in length. *Calyx* very short. Thunberg. We formerly examined this species in professor Van Royen's herbarium, but are not possessed of a specimen. It must be presumed that by "*folia integra" is not meant undivided leaves, the true sense of that expression; because no *Vaccinium* has any other. The learned author evidently contrives this phrase with the *folia ferrata* of the preceding species, and means that the leaves are nearly entire; in contradistinction to *intermissa*.

Michaux describes this shrub as having the aspect of *Myrica Gale*, with slightly downy branches. *Leaves* veiny. The *flower-flasks* shorter than the flowers, burst from a bud, composed of numerous crowded scales, but become naked and corymbose as the fruit advances. We trust that we need not labour under the necessity of precisely retaining the original specific name.

18. *V. ligustrinum*. Privet-leaved Whortle-berry. Mi-

**Vaccinium.**
VACCINIUM.

Lamarck and their fpecies twice mollently and their rub. I thofe long-lical, orientalis lenberg, beneath, broad, before 42. of hack. Beneath, branches, Calyx green. Berries large, blueifh smooth, nearly ferrated, Calyx five-lobed. Native of the loftieft parts of the ifland of Madeira, where it forms impenetrable thickets, flowering in July, according to Mr. Mallon, who fent a fpecimen to the younger Linneus in 1777. This fo prefhly agrees with Mr. Edwards's figure in Curtis's Magazine, drawn from a plant obtained from mount Caucafus, by Mr. Lock-who, that we cannot doubt its being what Pallas found in the alpine beechnets of that neighbourhood. The younger Linneus obtained a fpecimen of the fame, from the English gardens; and we received one in flower, from the preift duke of Marlborough's garden, at White Knight's, in June 1806. So far therefore our cultivated plant is identified, nor can any thing be more clearly diflinguished from the true V. Arctofothaphus. The leaves, well compared by Pallas to thofe of the Bird-cherry, are of a more firm rigid texture, and not half fo large as the former; they are more rounded at the bafe; their ferratures, though fmall, more evident; underfurface quite smooth, except at the very bafe about the mid-rib, which is also a little hairy on the upper fide. Footstalks longer. Calyx more decidedly five-lobed, though it appears to vary in the depth of its fegments. Corolla larger, pale green, with a purple tinge; sometimes it seems to be all over purple externally. Partial or internal bracteas rather broader. German very glaucous. The filaments differ effentially, in being flat, quite smooth at each fide, and only flightly fringed in the margin, efpecially about the top. We can difcern no spurs on the anthers, which moreover are rather thorter with refpeét to the corolla. The style is sometimes a little prominent, but not confiftantly. Pallas lays the berries are black, juicy, catabile, grateful aciety. Sometimes, though very rarely, he found the flowers four-cleft.

21. V. Arctofothaphus. Oriental Bear-berry, or Whortle- 
berry. Linn. Sp. Pl. 500. Wild. n. 21. (Vitis idea orientalis maxima, cerai folio, flore variagato; Tourn. Cor. 42. Voyage v. 2. 98, with a figure.)—Clufers lateral. Bracteas all at the fide of the partial falks. Leaves elliptical, acute, minutely ferrated; hairy beneath. Stamens as long as the bell-shaped corolla, with very hairy filaments. Calyx flihtly five-lobed.—Gathered on the caft of the Black tea, by Tournefort, two of whose fpecimens are before us. He describes this fbrub as the height of a man, with a trunk as thick as one's arm. The young leafy branches are downy on two oppofite fides, like the foregoing, but more broadly. Footfalks extremely fhort and broad, hairy. Leaves plant, broadly elliptical, tapering at each end, two inches and a half long, and nearly one and a half broad, bright green, sometimes reddish above, and quite smooth, except the midrib, on that fide; paler beneath, and befprinkled with short prominent hairs, efpecially about the lower part of the rib; their margin furri- nipped with copious, but blunt and fllllow, ferratures. Clufers from the wood of the preceding year, below the leafy fhoots, drooping, one and a half or two inches long, somewhat hairy, composed of eight or ten pendulous flowers, of a dirty white, ftripped or fliined with purple. Bracteas feveral at the bafe of each partial flower-falk, fringed; one of them large, ovate, often balf an inch, or more, in length; the elf linear-lanceolate, much smaller, one or two in number, fcarcey more, being analogous to thofe found about the middle of the partial falks, in feveral fpecies already defcribed, though differently ufuated in the corolla bell-shaped, five lines long and four wide, with five fllllow, recurved, marginal fegment. Filaments ten, nearly half as long as the corolla, fliht, gibbous, extremely hairy at the back. Anthers longer than the filaments, yellow, fliht, smooth, and tubular above, furnished with two granulated pouches, defcending much below their infcription, at the inner fide of the filament, and with two small dorsal fpur, at the bafe of the tubes above thofe pouches. Style fhorter than the corolla. The berries were feen by Tournefort in an unripe state only. He judges this plant, with great probability, to be the arctofothaphus, or Bear-grape of Galen.

What the variety B of Linneus may be, we know not, as nothing anfwerable to his reference is to be found in Tour- 
nefort's Corollarium.

22. V. padifolium. Madeira Whortle-berry. (V. Arctof- 
lanceolate, acute, minutely ferrated, smooth on both fides, except the mid-rib. Stamens nearly as long as the bell-shaped corolla, with fliht, slightly fringed, filaments. Calyx five-lobed. Native of the loftieft parts of the ifland of Madeira, where it forms impenetrable thickets, flowering in July, according to Mr. Mallon, who fent a fpecimen to the younger Linneus in 1777. This fo prefhly agrees with Mr. Edwards's figure in Curtis's Magazine, drawn from a plant obtained from mount Caucafus, by Mr. Lock-who, that we cannot doubt its being what Pallas found in the alpine beechnets of that neighbourhood. The younger Linneus obtained a fpecimen of the fame, from the English gardens; and we received one in flower, from the preift duke of Marlborough's garden, at White Knight's, in June 1806. So far therefore our cultivated plant is identified, nor can any thing be more clearly diflinguished from the true V. Arctofothaphus. The leaves, well compared by Pallas to thofe of the Bird-cherry, are of a more firm rigid texture, and not half fo large as the former; they are more rounded at the bafe; their ferratures, though fmall, more evident; underfurface quite smooth, except at the very bafe about the mid-rib, which is also a little hairy on the upper fide. Footfalks longer. Calyx more decidedly five-lobed, though it appears to vary in the depth of its fegments. Corolla larger, pale green, with a purple tinge; sometimes it seems to be all over purple externally. Partial or internal bracteas rather broader. German very glaucous. The filaments differ effentially, in being flat, quite smooth at each fide, and only flightly fringed in the margin, efpecially about the top. We can difcern no spurs on the anthers, which moreover are rather thorter with refpeét to the corolla. The style is sometimes a little prominent, but not confiftantly. Pallas lays the berries are black, juicy, catabile, grateful aciety. Sometimes, though very rarely, he found the flowers four-cleft.
24. *V. meridionale*. Jamaica Whortle-berry. Swartz Ind. Occ. 676. Wild. n. 22. Ait. n. 17.—Clusters erect, downy. Bracteas solitary, ovate. Leaves ovate, crenate, permanent, smooth. Stem arborescent.—Native of the lofty Blue mountains in the southern part of Jamaica, flowering in February, and ripening fruit in Augult. This is from ten to thirty feet high, with a very straight smooth trunk, and hard wood. Branches straight, forking, leafy, round; downy when young. Leaves rigid, an inch or rather more in length, on short, broad, downy flarks, flat, and somewhat shining, veiny; paler beneath. Clusters solitary near the end of last year's branches, twice as long as the leaves; their partial flarks naked, except a large, solitary, ovate, smooth, coloured, deciduous bractea, at the base of each, and equal to it in length. Flowers drooping, reddish-white. Calyx in four broad, acute, permanent segments. Corolla ovate, quadrangular before expansion, contracted at the mouth, with four acute, recurved, marginal segments. Stamens eight, as long as the corolla, their filaments hairy in the middle. Dr. Swartz mistakes the tubular points of the authors for horns or spurs. Style the length of the corolla. Berry roundish, juicy, pleasantly flavoured, pale red, resembling that of *V. Vilis idea*. The flowers are very rarely five-cleft and decandrous.

25. *V. cercum*. Otaheit Whortle-berry. Forl. Prod. 28. Wild. n. 5. (Andromeda cera; Linn. Suppl. 238.)—Stalks axillary, solitary, single-flowered, with two lanceolate bracteas about the middle. Leaves roundish-ovate, ferrated, smooth, permanent. Calyx in five broad pointed segments.—Gathered by Forther in Otaheite. The branches are round, smooth, leafy; slightly downy when young. Leaves about an inch long, pointed, coriaceous, veiny, twice the length of the smooth simple flower-flarks. Corolla ovate-oblong, with five angles, and five erect small segments. Anthers, according to Linnæus, with two dorsal horns.

26. *V. Vilis idea*. Red Whortle-berry, or Cow-berry. Linn. Sp. Pl. 502. Wild. n. 24. Fl. Brit. n. 3. Engl. Bot. t. 508. Pursh n. 18. Fl. Dan. t. 140. (Vaccinia rubra; Ger. Em. 1415. Vilis idea rubra; Camer. Epit. 136.)—Clusters terminal, drooping; with ovate concave bracteas, longer than the flower-flarks. Leaves obovate, revolute, minutely toothed; dotted beneath. Corolla bell-shaped.—Native of dry barren stony woods and heaths, in the north of Europe, plentiful in Scotland, Welfordeland, Derbyshire, Wales, &c. flowering in June, and ripening fruit in August. Mr. Pursh says it occurs on rocks near the sea-coast, from Canada to New England, but the American plant is more robust than the European, with considerably larger leaves. The roots are creeping, woody. Stems ascending, in England about a span high, wary, but little branched, smooth, leafy; young branches round, downy. Leaves evergreen, somewhat like box, but darker on the upper side, smooth and shining. Flowers pale pink, four-cleft, in elegant, dense, solitary, pendulous clusters. Calyx in four deep, broad, ovate, red segments. Anthers without horns. Stigma small, feebly notched. Berries blood-red, acid, acidulous and bitter, ells pellable in tarts than either the Cranberry or Bilberry, but excellent in a rob or jelly, for colds and sore-throats, as well as to eat with roast meat, to which latter purpose this jelly is universally applied by the Swedes.

28. *V. crassifolium*. Thick-leaved Whortle-berry. Andr. Repof. t. 105. Ait. n. 19. Pursh n. 20. Curt. Mag. t. 1152.—Clusters lateral and terminal, coriaceous. Bracteas shorter than the flower-flarks. Leaves elliptical, crenate, smooth; paler and veiny beneath. Corolla bell-shaped. Stem diffuse.—Brought by Mr. Fraer from Carolina, in 1787. It flowers in May and June. A trailing evergreen species, requiring some shelter from our variable winters and springs. The leaves are not an inch long; their upper surface very smooth and even, with a little minute pubescence on the mid-rib and footflask. Flowers five-cleft, prettily variegated with pink and white, drooping, on red coriaceous flarks. Stems hairy. We have no account of the fruit.

29. *V. villosium*. Fairy Mexican Whortle-berry.—Clusters longer than the leaves. Flower-flarks large, corolla and lanceolate bracteas densely hairy. Leaves elliptical, entire, revolute, coriaceous, with a blunt point; hairy on the upper side.—Sent by Mutis to Linneaus from Mexico. The branches are round, leafy, densely hairy when young. Leaves crowded, an inch long, on thick downy footflarks; their upper side convex; under paler, veiny, scarcely hairy, except the rib. Clusters towards the ends of the younger branches, axillary, dense, drooping, nearly twice as long as the leaves, very hairy all over, the germs particularly. Bracteas coloured, internally smooth; those of the partial flarks very narrow. Calyx in five deep, lanceolate, densely fringed segments. Corolla purplish, oblong, with five hairy angles, and as many small recurved teeth. Fruit unknown, but the habit, and the inferior germs, sufficiently announce the genus.

30. *V. reticulatum*. Reticulated South-sea Whortle-berry.—Stalks axillary, solitary, single-flowered, downy. Leaves obovate, more or less ferrated, coriaceous, with a blunt point; strongly reticulated on both sides and nearly smooth. Corolla hairy.—Gathered by Mr. Menzies, in woods on high mountains, in the Sandwich islands.—The branches are leafy; when young angular and feebly downy. Leaves an inch long, remarkable for their reticulated veins, prominent on both sides; their margin somewhat revolute, strongly ferrated, but sometimes nearly entire. Flower-flarks numerous, erect, about an inch long, swelling upwards, without bracteas; reflected as the fruit advances. Calyx in four or five deep, oblong, ribbed, downy, coloured segments, at length involute. Corolla cylindrical, three as long as the calyx, purple, slightly hairy, with four or five upright blunt teeth. Style hairy, shorter than the corolla. Berry globular, depressed, nearly or quite smooth.

31. *V. dentatum*. Toothed South-sea Whortle-berry.—Stalks axillary, solitary, single-flowered, smooth. Leaves obovate, with sharp tooth-like ferratures, coriaceous, veiny, very smooth. Calyx longer than the smooth germs.—Found by Mr. Menzies, in woods on the lofty mountains of the Sandwich islands. The branches of this are angular, always smooth, like even other parts. Leaves rather longer than the leaf, more strongly and uniformly toothed, with less prominent veins. Flower-flarks naked and smooth; recurved when in fruit. Calyx in five deep, oblong, obtuse, smooth, keeled segments, longer than the germs, even after the corolla is fallen, which latter is wanting in our specimens.

VACCINIUM.

t. 480. Pursh n. 21. Ait. Epit. 376. Curt. Mag. t. 1550.—Clufters terminal, corymbose. Bracteas shorter than the flower-flalks. Leaves elliptic-obovate, acute, crenate, smooth and thinning. Corolla cylindrical. —Native of Carolina, flowering in May and June. The flon is of humble growth, either erect, as in Andrews's figure, or diffuse, as in the Botanical Magazine; the young branches downy on two opposite fides. Leaves evergreen, from an inch to an inch long, numerous, very smooth; paler and velvety beneath; on very short red footsalks. Flower-flalks, bracteas, and calyx very smooth, of a thining red or purple. Calyx in five fold, rather shallow, segments. Corolla ovate-oblong, white or pink, with five flight spreading teeth, longer than the style. This species bears some affinity to the following, as well as to crafisphium, n. 28; but differs from the latter effentially, as Mr. Pursh observes, in the fhape of its corolla; to which may be added the form and polish of its leaves, and the young branches being downy on two fides only.

36. V. obtusum. Blunt Whortle-berry. Pursh n. 25.—"Stem creeping. Leaves small, oval, rounded and blunt at each end, pointed, entire, coriaceous, smooth. Stalks axillary, solitary, fingle-flowered."—Gathered by Mr. Menzies, on the north-west coast of America; seen in the Bankfather herbarium, without flowers. Pursh.

We can find nothing, among our fpecimens from Mr. Menzies, that anwers to the characters of either of these two fpecies. Our paraisophium, n. 3, agrees in some points with the defcription of the lat, but the flon is rather arborefcent than creeping, and the leaves are certainly neither coriaceous nor evergreen.

37. V. Oxycoccus. Common Cranberry. Linn. Sp. Pl. 500. Wild. n. 25. Fl. Brit. n. 4. Engizl. Bot. t. 195. Fl. Dan. t. 80. Lamarck f. 3. (Vaccinia palustris; Ger. Em. 1419. Lob. ic. v. 2. 109. Oxycoccus; Cord. Hist. 140. 2. f. 1. Oxycoccus vulgaris; "Perf. Syn. v. 1. 419." Pursh 263.)—Corolla deeply four-fleck. Leaves ovate, entire, revolute, acute, fmoother. Stems creeping, thread-shaped. Flowers terminal.—Native of turf y mossy bogs in the mountainous parts of Europe; common in Switzerland, Russia, Scotland, Ireland, and the north of England, as well as in Lincolnshire, and the neighbouring part of Norfolk, flowering in June. Mr. Pursh speaks of it as common on the boggy mountains of North America, from Canada to Pennsylvania, flowering from May to July. Few plants are more elegant. The wiry thubby flons creep among bog-mofs, with long, branching, fibrous roots, which often appear to imbibe nourishment from the clear water alone. Branches scattered, procumbent, smooth, reddish, leafy. Leaves evergreen, flalked, from a quarter to half an inch long, coriaceous; convex and of a dark thinning green above; glaucous beneath. Flower-flalks few together about the tops of the branches, somewhat corymbose, above an inch long; simple, red, flightly hoary, bearing two minute bracteas in the lower part, and a solitary, drooping, very beautiful, four-fleck flower at the top. The germen is fmoother. Calyx-lobes broad and shallow. Corolla pink, with refixed oblong fragments, a quarter of an inch in length. Filaments purple, fmoother. Anthers yellow, converging, without flurs. Berry pear-shaped or globular, often fpotted, crumifon, of a peculiar flavour, somewhat like black currants, with a frong acidity, grateful to most people, in the former parts, for which purpofe they are largely imported from Russia. We can remember Cranberries from Lincolnshire, and the north-west corner of Norfolk, being fold in cart-loads about the freets of Norwich; but the extensive enclosures have, in many parts, deftroyed and drained their native bogs. Lightfoot records that at Longtown, on the borders of Cumberland, not less than twenty or thirty pounds-worth were fold each market-day, for five or six weeks together, and difpofed over different parts of the kingdom. In Sweden these berries serve only to boil silver plate to its due degree, with whitefets, their fhard acid corroding the superficial particles of the copper alloy.

38. V. macrocarpon. American Cranberry. Ait. Hort. Kew. ed. 1. v. 2. 13. t. 7. ed. 2. n. 22. Wildl. n. 27. Lamarck f. 4. (V. Oxycoccus f; Michaux Boreal.-Amer. v. 1. 228. "V. hipidulum; Wangenh. Amer. 168. t. 30. f. 67." Oxycoccus macrocarpus; Pursh 263.)—Corolla deeply four-fleck. Leaves elliptic-oblong, entire, flightly revolute, obtufe, fmoother. Stems ascending. Flowers fideal. —In bogs principally in a sandy soil, and on high mountains, frequent, from Canada to Virginia, flowering from May to July. A larger and more upright plant than the lat, with less convex, more oblong, much larger leaves. Several flowers come forth at the ends of the lat's branches, furmounted by the fhoots of the present year. Their bracteas are Situated towards the top of each falk, and, as well as the segments of the corolla, are larger than in the Common Cranberry. The flons however are shorter in proportion to their anthers, which are usually long. The berries are larger, and of a brighter red than the lat, collected in great abundance, for making tarts, in America, and exported from thence to Europe; but they always prove here far inferior in quality to the Russian Cranberry.
berries, however excellent in America. The best method of having American Cranberries in Europe, is by cultivation in an artificial bog with great plenty of water, as first contrived by Sir Joseph Banks. A very few square yards of ground thus employed, will yield as many Cranberries as any family can use. If allowed to hang till they are fully ripe, as late as October, they are even better than the Oxycoccus, and may be kept dry in bottles throughout the year. Our wild Cranberries have generally been gathered too early; as may also be the case with those brought from America.

We have seen no specimen of this species. Its fruit might be an acquisition to our tables, if railed in the same mode as the last.

In the above ample detail of the genus Vaccinium, which we trutl will prove acceptable to those who have ever attended to its former confussion, we have removed eight of Willdenow's species. Four of these are album, macronatum, ligustriinn and bifidum of Limnus, the latter being referred by Mr. Purth to Gaultheria by the name of ferfulisomnia; see that article, where this species should be introduced next to procumbens, with the following character. "Stem creeping, hispid. Leaves roundish-oval, acute. Flowers four-cleft, axillary, solitary, nearly feline. Corolla bell-shaped." (Vaccinium bifidum; Linn. Sp. Pl. 500. Willd. n. 26. Michaux Boreal.—Amer. v. t. 228. t. 23.)—In molly swamps, particularly where Cedars and other evergreens abound, from Canada to Pennsylvania, flowering in April and May. A small creeping plant. Berries white, very sweet, and agreeable to eat. Purth.—The other four discarded species of Willdenow are fulcatum, venugulum, amasun and virgatum of Dr. Solander, in Ait. Hort. Kew. ed. 1; the reasons of which rejection are to be found under our 13th and 17th species,—On the other hand, we have augmented this genus with seven entirely nondefcript species, for most of which we are obliged to the bounty of our often-mentioned friend Mr. Archibald Menzies; as well as with twelve others from Michaux, Purth, and our several English garden botanists and publishers. On this subject we would particularly direct our fellow-labourers to the plants hitherto confounded under V. Arctostraphylos, and the still-pupioed varieties of that interesting species; relating to which, discoveries are probably yet to be made, in the wilds of Tartary and the Levant, and possibly even in the greenhouses of France and England.

Vaccinium, in Gardening, comprehends many sorts of hardy, dwarf, under-shrubby, ligneous, evergreen, and deciduous plants, among which the species most commonly cultivated are those of the black whortle, or bilberry (V. myrtillus); the white Pennsylvanian whorts, or bilberry (V. album, see the preceding article); the red whortleberry (V. vitis idea); the cranberry, moss, or moor berry (V. oxyccocus); the marsh whortle, or great bilberry-bush (V. uliginosum); the hispid-flaked American whortleberry (V. hispidulum, see the preceding article); the corymbous-flowering American whortleberry (V. corymbosum); the privet-leaved Pennsylvanian whort-leberry (V. ligurstinum); and the flaminious American whortleberry (V. flaminium).

The first has slender, branching, shrubby flanks, about two feet in height, and produces large edible berries of a blackish-red colour. The second is a similar plant, producing small berries of a whitish colour. The third is a more dwarfish plant, producing clusters of nodding, reddish flowers, and red juicy berries of great value for tarts, and other culinary uses. The fourth has slender creeping flanks, which produce reddish edible berries of great value and importance for different culinary well-known purposes, as in pies, tarts, &c. The fifth has a woody, shrubby, branching flank of some height, and affords whitish purple flowers, and large berries. The sixth grows with slender, trailing, rough flanks, and yields large red berries. The rest are all American plants.

Method of Culture.—They may all be raised from seeds, or offset root-fuckers, creeping roots, and trailing rooting flanks. Those also growing with several rooted flanks and branches, may be divided in the root and top, into separate plants, in which way they succeed very well.

The seeds should be sown, where that method is purposed, in the autumn as soon as they are ripe and gathered, in a shady border, or the places where the plants are to grow and remain; and when the young plants are up, they should be kept clean, and be removed with earth about their roots, as there may be occasion.

The offsets and root-plants may be set out in the same seadon in proper places, which for the first four sorts are those where the soil is of a cold, light, sandy, heathy, moosy, moosy, or woody nature, and for the two succeeding ones in marshy and boggy situations; as these have the moat resemblance to those in which they grow naturally, and are the most prosperous. It may likewise be advisable in many cases to take the plants from their native situations with balls of earth about their roots. Some, however, succeed in the common borders and other parts. They may in some cases be removed in the spring season, but the other is the better way.

They are admitted into gardens and pleasure-grounds for the sake of variety, curiosity, and ornament, and some of them are cultivated for the use of their fruit. In its natural situation, that of the cranberry is often an object of very great importance, affording the poor gatherers of its berries considerable employment as well as much money. It delights most in rather wet, mossy, mossy situations.

The vaccinium oxyccocus of Limnus, or cranberry, may be preferred perfect for several years, merely by drying it a little in the sun, and then flopping it closely in dry bottles. The vaccinium myrtillus, or bilberry, yields a juice, which has been employed to stain paper, or linen, purple. In autumn the moor-game chiefly live upon the product of this shrub.

VACERRI. See Druids.

VACH, or Vakh, in Mythology, a name of the Hindoo god of Sarafati; faksi, or comfort of the creative power in the Tirmaur, or divine Triad of the East. The name Vach, or Vachi, is derived from speec, Sarafati being goddess of eloquence; and hence called also Vachdevi. Vachapaty, a title equivalent to lord of eloquence, is sometimes applied to

7
to the regent of the planet Jupiter, whom the Hindoos call 
Brahmapati; which see.

VACHA, in Geography, a town of Germany, in the prin-
cipality of Upper Hesse, on the Werra; 20 miles N.E. of 
Fulda.—Also, a town of Germany, in the margraveate 
of Anspach, on the Rednitz; 25 miles N.E. of Anspach.—
Also, a town of Peru, in the diocese of La Paz; 8 miles 
S.W. of La Paz.

VACHE, or Cavo's Island, an island about twelve miles 
from the south coast of Hispaniola, about twenty-four miles 
in circumference. It was formerly a place of rendezvous 
for pirates and freebooters, and is provided with three ports, 
one of which can receive vessels of 300 tons. N. lat. 18° 5'.
W. long. 74° 25'.

VACHET, or Cabre, and Bulk Rocks, rocks on 
the south coast of Newfoundland, a little to the eall of 
Placentia bay.

VACHELUSE, one of the Lipari islands; 3 miles S. 
of Stromboli.

VACHER, a town of France, in the department of 
the Upper Loire; 9 miles S. of Le Puy en Velay.

VACHON, Pierre, in Biography, an eminent performer 
on the violin, was born in Provence, 1732. After perfor-
mimg at the concert spiritual with great applause, he was placed 
at the head of the prince of Conti's fect band. In 1784, he 
was appointed concert-master to the king of Prussia at 
Berlin, after refiding some time in London, and leading at the 
Opera. He was one of the most certain and agreeable 
performers on the violin of his time, particularly in trios and 
quartets. He was likewise a composer of considerable merit, 
having furnished the different theatres of Paris with fix or 
eight successful musical dramas, and the performers on his 
instrument with several books of solos, quartets, and con-
certos, which were practicable and in a pleasing style. He 
had an extreme melancholy expression of countenance, of 
which he was not insensible, and used to say, in pleafantrty, 
"Ma triste countenance m'a fait beaucoup de mal auprès les 
dames."

VACA, or VACZ, in Geography. See Waitzen.

VACIAN, a town of Abafia; 15 miles S. of Alkasy.

VACKALEER, a town of Hindooitan, in Mylore; 
27 miles E.N.E. of Bangalore.

VACOMAGI, in Ancient Geography, a people of the isle 
of Albion, S. of the Caledonii, whose towns were Banata, 
Tamaa, the Winged Camp, or Alata Caima, and Turcf.

VACONE, in Geography, a town of the Popedom, in 
the duchy of Spoleto; 8 miles S.E. of Narni.

VACONTIUM, in Ancient Geography, a town of Lower 
Pannonia, at a distance from the Danube.

VACUA, Italy, in Myseo, a white open note; in old Eng-
lith, a void; in opposition to notes with black heads, like 
crotchets and quavers. In the first time-table all the 
notes were black, till the invention of the femibreve and minim.

VACUNA, in Mythology, a goddes held in high venera-
tion among the Sabines.

VACUNALIA, a festival kept in honour of the goddes 
Vacuna, who presided over those that were unemloyed or 
at rest. It was celebrated in December by the country labourers, 
after the fruits were gathered in, and the land tilled.

Ovid speaks of it in his Fasti, lib. vi.

"Nam quoque cum festa antiqua facra vacuna, 
Ante vacuales flanteque, fedentque focos."

The worship of Vacuna was very ancient in Italy, and 
established among the Sabines long before Rome was foun-
ded. Some take her for Diana, Venus, or Ceres, and
others for Bellona or Victoria. Varro thinks she was Mi-
erva.

VACUP, in Geography, a town of Bofnia; 32 miles S.W. 
of Saraje.

VACUUM, VACUITY, in Physics, a space empty or de-
void of all matter, or body.

Whether there be any such thing in nature as an absolute 
vacuum; or whether the universe be completely full, and 
there an absolute plenum, is a thing that has been contro-
verted by the philosophers of all ages.

The ancients, in their controversies, distinguished two 
kiinds; a vacuum coacervatum, and a vacuum interfusum, or 
difformantum.

Vacuum coacervatum, is conceived as a place defiitute of 
matter; such, e. gr. as there would be, should God anni-
hilate all the air, and other bodies within the walls of a 
chamber.

The existence of such a vacuum is maintained by the 
Pythagoreans, Epicureans, and the Atomists, or Corporu-
scularians; most of whom affect such a vacuum actually to exiit 
without the limits of the sensible world. But the modern 
Corpuscularians, who hold a vacuum coacervatum, deny that 
appellation; as conceiving, that such a vacuum must be in-
finte, eternal, and uncreated.

According, then, to the later philosophers, there is no 
vacuum coacervatum without the bounds of the sensible 
world; nor would there be any other vacuum, provided 
God should annihilate divers corporous bodies, than what 
amounts to a mere privation, or nothing; the dimensions of 
such a fpace, which the ancients held to be real, being by 
these held to be mere negations; that is, in such a place, 
there is no length, breadth, and depth wanting, as a 
body must have to fill it. To suppofe, that when all the 
matter in a chamber is annihilated, there should yet be real 
dimensions, is to fuppofe corporeal dimensions without body; 
which is absurd.

The Cartesians, however, deny any vacuum coacervatum at 
all; and affirm, that if God should immediately annihilate all 
the matter, v. gr. in a chamber, and prevent the ingrefs 
of any other matter, the consequence would be, that the 
walls would become contiguous, and include no space at all. They 
add, that if there be no matter in a chamber, the walls can 
be conceived no otherwise than as contiguous; these things 
being faid to be contiguous, between which there is not any 
thing intermediate: but if there be no body between, there 
is no extention between; extention and body being the fame 
thing; and if there be no extention between, then the walls 
are contiguous, and where is the vacuum?

But this reafoning is founded on a mistake, viz. that body 
and extention are the fame thing. See Matter.

Vacuum interfusum, or interfusum, is that supposed 
to be naturally interfused in and among bodies, in the pores 
of the fame body, and in the interstices between different 
bodies.

It is this kind of vacuum which is chiefly disputed among 
the modern philosophers; the Corpuscularians strenuously 
afferting it; and the Peripatetics and Cartesians as tena-
ciously impugning it. See Cartesian and Leibnitzian.

The great argument the Peripatetics urge against a va-
cuum interfusum is, that there are divers bodies frequently 
seen to move contrary to their own nature and inclination: 
and that for no other apparent reason, but to avoid a va-
cuum; whereas they conclude, that nature abhors a vacuum, 
and gives us a new class of motions ascribed to the force 
vacui, or nature's flying a vacuum. Such, they say, is the 
riie of water in a syringe, upon the drawing up of the 
 piston; such also is the ascent of water in pumps, and the 

3 X 2 

swelling
VACUUM.

swelling of the flesh in a cupping-glass, &c. But since the weight, elaticity, &c. of the air have been ascertained by pure experiments, those motions and effects are universally ascribed to the gravity and prehure of the atmosphere.

The Cartesians deny not only the actual existence, but even the possibility of a vacuum: and that on this principle, that extension being the essence of matter, or body, wherever extension is, there is matter; but mere space, or vacuity, is suppos’d to be extended; therefore it is material. Who-

ever affords an empty space, they say, conceives dimensions in that space, i.e. he conceives an extended subsistance in it; and therefore he denies a vacuum, at the same time that he admits it.

Des Cartes, if we may believe some accounts, rejected a vacuum from a complaisance to the tarte which prevailed in his time, against his own first sentiments; and among his familiar friends used to call his systen his philosophical romance.

On the other hand, the corpuscuar authors prove, not only the possibility, but the actual existence of a vacuum, from divers considerations; particularly from the consideration of motion in general; and that of the planets, comets, &c. in particular; from the fall of bodies; from the vibration of pendulums; from rarefaction and condensation; from the different specific gravities of bodies; and from the divisibility of matter into parts.

1. It is argued, that motion could not be effected without a vacuum. This is what Lucretius urg’d long ago.

"Principium quoniam cedendi nulla daret res, — unique materies quoniam flippata sufficit."

The force of this argument will be increas’d from the two following considerations: viz. first, that all motion is either in a straight line, or in a curve, which returns into itself, as the circle and ellipse; or in a curve that does not return into itself, as the parabola, &c. And, secondly, that the moving force must always be greater than the refiiance.

From hence it follows, that no force, even though infinite, can produce motion where the refiiance is infinite; consequently, there can be no motion either in a straight line, or a non-returning curve: because, in either of those cases, the protrusion, and consequently the refiiance, would be infinite.

There remains, therefore, only the motion of a revolving curve practicable: this must either be a revolution upon an axis, or an annular motion round a quiescent body; both which are, again, impossible in an elliptic curve; and, consequently, all motion must be in circles geometrically true; and the revolving bodies must either be spheres, spheroids, cylinders, or portions of them, exactly geometrical; otherwise the revolutions in a plenum would be impossible: but such motions, or such figured bodies, we do not know in nature. Therefore there is a vacuum.

2. The motions of the planets and comets demonstrate a vacuum: thus if Isaac Newton, — "That there is no such fluid medium as aether," (to fill up the porous parts of all the bodies, as the air and intercellular parts, and so make a plenum,) "seems probable; because the planets and comets proceed with so regular and lauful motion through the celestial spaces, both from and to all parts; for hence it appears, that those celestial spaces are void of all sensible refiinance, and consequently of all sensible matter. For the refiining force of fluid mediums arieth partly from the attraction of the parts of the medium, and partly from the inactivity of matter. Now, that part of the refiinance of any medium, which arieth from the tenacity or attraction of its parts, may be lessen’d by dividing the matter into smaller parts, and rendering those parts more smooth and slippery; but that part of the refiinance which arieth from the inactivity of matter, is always in proportion to the density of the matter; nor can it be diminished by dividing the matter, nor by any other means, except by diminishing the density thereof.

"Consequently, if the celestial regions were as dense as water, or as quicksilver, they would refiil almost as much as water or quicksilver; but if they were perfectly dense without any imperfect vacuity, though the matter were ever so fluid and subtile, they would refiil more than quicksilver does; a perfectly solid globe, in such a medium, would lose above half its motion, in moving three lengths of its diameter; and a globe not perfectly solid, such as the bodies of the planets and comets are, would be stopped still sooner. Therefore, that the motion of the planets and comets may be regular and lasting, it is necessary the celestial spaces be void of all matter, except perhaps some few, and much rarefied effluvia of the planets and comets, and the passing rays of light."

3. The fame great author deduces a vacuum also from the consideration of the weights of bodies; thus: "All bodies about the earth gravitate towards the earth; and the weights of all bodies, equally distant from the earth’s centre, are as the quantities of matter in those bodies. If the aether, therefore, or any other subtle matter, were altogether destitute of gravity; or did gravitate less than in proportion to the quantity of its matter; because (as Aristotle, Des Cartes, and others, argue) it differs from other bodies only in the form of matter; the same body might, by the change of its form, gradually be converted into a body of the same constitution with those which gravitate more in proportion to the quantity of matter; and, on the other hand, the more heavy bodies might gradually lose their gravity, by gradually changing their form; and therefore the weights would depend upon the forms of bodies, and might be changed with them; which is contrary to all experiment."

4. The descent of bodies proves, that all space is not equally full; for the same author goes on, "If all spaces were equally full, the specific gravity of that fluid with which the region of the air would, in that case, be filled, would not be less than the specific gravity of quicksilver or gold, or any other the most dense body; and therefore neither gold, nor any other body, could descend therein. For bodies do not descend in a fluid, unless that fluid be specifically lighter than the body. But, by the air-pump, we can exhaust a vessel, till even a feather shall fall with a velocity equal to that of gold in the open air: the medium, therefore, through which this feather falls, must be much rarer than that through which the gold falls in the other case."

"The quantity of matter, therefore, in a given space, may be diminished by rarefaction; and why may not it be diminished in infinitum? Add, that we conceive the solid particles of all bodies to be of the same density; and that they are only rarefiable by means of their pores: and hence a vacuum evidently follows."

5. "That there is a vacuum, is evident from the vibrations of pendulums; for since those bodies, in places out of which the air is exhausted, meet with no resistance to retard their motion, or shorten their vibrations; it is evident there is no sensible matter in those spaces, or in the occult pores of those bodies."

As to what Des Cartes urges of his materia ubitatis, that its tenuity prevents its refiinance from being sensible; and that a small body, striking against a greater, cannot in the least move, or refiil the motion of that other; but is re-
VACUUM.

acted back again with all its momentum; it is contrary to all experience. For Sir Isaac proves, that the density of fluid mediums is proportionable to their refistances, very nearly; and that they are exceedingly mistaken, who suppoze the refistance of projectiles to be infinitely diminished, by dividing the parts of the fluid, even in infinitum (Princip. lib. ii. prop. 38.) when, on the contrary, it is clear the refistance is but little diminished by the subdivision of the parts (ibid. prop. 40.,) and that the refilling forces of all fluids are nearly as their deneties. — For why should not the same quantity of matter, whether divided into a great number of subtile parts, or into a few larger ones, have the same refilling force? If there were no vacuum, it would follow, that a projectile moving in the air, or even in a space whence the air is exhausted, should move with as much difficulty as it would in quicksilver; which is contrary to experience.

Nor will it avail to suppoze the particles of the subtile fluid, constituting a plenum, to move conftantly and equally in all directions; and by favour of this hypothesis, to imagine that they act, but do not refit. Because the motion of a fluid favours the motion of a body in it, only as far as it is in the fame direction; and an infeline motion of the parts of the fluid, equal in all directions, cannot make the refistance lefs than if there was no motion of the parts. It is refuppozed by many that the particles of common fluids, e.g. water or air, are in a conftant infeline motion; but this does not hinder those fluids from refilling in proportion to their deneties.

If it should be alleged, that by refuppozing this dense fluid which replenishes space to penetrate the pores of bodies with the utmost freedom, (as light paffes through transparent bodies, and the magnetic and electric effluvia through most kinds of bodies,) its refistance will then be incomparably lefs than in proportion to its denety; the refistance in this cafe not being measured by the denety of the fluid, because the greater part paffes through the pores of the body in motion freely, without refistance: yet even on this hypothesis, the refistance of a golden ball in a plenum would be ftrictly very great. For this subtile fluid, how penetrating (over it be,) must refit the solid parts of the ball; which cannot move in the fluid without displacing its parts, and loosing as much motion as must be communicated to those parts; and this refistance depends on the quantity of solid parts in the ball; whereas the refistance which the fame ball meets with in quicksilver (which we suppoze to have no paffage through the ball,) depends on the quantity of the solid parts in an equal bulk of the quicksilver, which must be moved to make way for the ball. And this being lefs than the quantity of solid parts in an equal bulk of the golden ball, in proportion as the specific gravity of quicksilver is lefs than that of gold, it follows that the refistance of a golden ball, moving in such a subtile penetrating plenum, would be lefs than its refistance in quicksilver. The refistance of a golden ball in a plenum (how freely ever the matter conftituting it paffes through the pores of the ball, and how large and numerous these pores may be,) must correspond to the solid matter in the ball; which is greater than the solid matter in any equal bulk of any of our fluids, upon which their refistances depends.

6. That there are interfpered vacuities, appears from matter's being actually divided into parts, and from the figures of those parts; for, on supposition of an absolute plentitude, we do not conceive how any part of matter could be actually divided from that next adjoining, any more than it is possible to divide actually the parts of absolute space from one another: for by the actual division of the parts of a continuum from one another, we conceive nothing else underfoot, but the placing of those parts at a distance from one another, which, in the continuum, were at no distance from one another: but such divisions between the parts of matter must imply vacuities between them.

7. As for the figures of the parts of bodies, upon the supposition of a plenum, they must either be all rectilinear, or all concavo-convex; otherwise they would not adequately fill space; which we do not find to be true in fact.

8. The denying a vacuum, suppozes what it is impossible for any one to prove to be true; viz. that the material world has no limits.

However, we are told by some, that it is impossible to conceive a vacuum. But this surely must proceed from their having imbibed Des Cartes's doctrine, that the effence of body is constituted by extenlion; as it would be contra-dictory to suppoze space without extenlion. To suppoze that there are fluids penetrating all bodies and replenishing space, which neither refit nor act upon bodies, merely in order to avoid admitting a vacuum, is feigning two forts of matter, without any necifity or foundation; or is tacitly giving up the question.

Since then the effence of matter does not confit in ex-tenlion, but in fluidity and impenetrability, the universe may be faid to confit of fluid bodies moving in a vacuum: nor need we at all fear, left the phenomena of nature, most of which are planfly accounted for from a plentitude, should become inexplicable when the plenum is set aside. The principal ones, such as the tides; the fuppenlion of the mercury in the barometer; the motion of the heavenly bodies, and of light, &c. are more eafily and satisfactorily accounted for from other principles. See Tides, &c.

VACUUM, or Vacuum Boyleanum, is also used, somewhat abufively, to express that approach to a real vacuum, which we arrive at by means of an air-pump.

Thus, any thing put in a receiver to be exhausted, is said to be put in vacuo: and thus, most of the experiments with the air-pump are said to be performed in vacuo, or in vacuo Boyleanum. Some of the principal phenomena observed of bodies in vacuo, are: that the heaviest and lightest bodies, as a guinea and a feather, fall here with equal velocity: — that fruits, as grapes, cherries, peaches, apples, &c. kept for any time in vacuo, retain their nature, freshefs, colour, &c. and those withered in the open air recover their plumpness in vacuo: — all light and fire become immediately extinct in vacuo: — the collifion of flint and flécé in vacuo, produces no sparks: — no found is heard, even from a bell rung in vacuo: — a square phial, full of common air, well closed, breaks in vacuo; a round one does not: — a bladder half full of air will heave up forty pounds weight in vacuo: — cats, and most other animals, soon expire in vacuo.

By experiments made in 1704, Dr. Derham found, that animals that have two ventricles, and no foramen ovale, as birds, dogs, cats, mice, &c. die in less than half a minute; counting from the first exflation: a mole died in one minute, a bat lived seven or eight. Insects, as waffps, bees, gnats, &c. seemed dead in two minutes; but after being left in vacuo twenty-four hours, they came to life again in the open air: fishes continued twenty-four hours in vacuo, without appearing much incommoded.

Seeds planted in vacuo do not grow: — small beer dies, and lofes all its taste, in vacuo: — likewarm water boils very vehemently in vacuo: — and air, rushing through mercury into a vacuum, throws the mercury in a kind of shower upon the receiver, and produces a great light in a dark room.
The air-pump can never produce a perfect vacuum; as is evident from its structure, and the manner of its working: in effect, every exsuction only takes away a part of the air; so that there will still be some left after any finite number of exsuctions. Add, that the air-pump has no longer any effect than while the spring of the air remaining in the receiver is able to lift up the valves; when the rarefaction is come to that degree, you can come nearer to a vacuum. Sir Isaac Newton, observing that a thermometer suspended in vacuo, and in that state removed to a warm or a cold room, receives the heat or cold, and rises, or falls, almost as soon as another in open air; takes thence occasion to suspect, that the heat of the warm room is conveyed through the vacuum, by the vibrations of a much subtilet medium than air, which remained in the vacuum after the air was drawn out. Opt. P. 325.

VACUUM, Torricellian. See Torricellian.

VADA, in Ancient Geography, a place which belonged to the Batavi, W. of Batavodurum.

VADA Sabatia, Vai, a town of Italy, in Liguria.

VADA Valatera, a place of Italy, in Etruria.

VADA, in Geography, a sea-port town of Etruria, at the mouth of the river Cecina; 18 miles S.W. of Volterra. N. lat. 43° 17'. E. long. 10° 30'.

VADACOURCHY, a town of Hindoostan, in Calicut; 10 miles S.W. of Palicaudchery.

VADAGARY, a town of Hindoostan, in Madura; 25 miles W. of Colpetta.

VADAMADERY, a town of Hindoostan, in the province of Dindigul; 15 miles N.E. of Dindigul.

VADAMIA, a town of the Arabian Trak, on the Euphrates; 105 miles W.N.W. of Baffora.

VADARI, in the Civil Law, denotes a peron to pledge, undertake, or give security, in behalf of another, that he shall, on a certain day, appear in court, to prosecute, or answer.

If he fails, his surety has an action vadamian decreti against him; that is, an action for defering his bail. See WAGNER.

Properly speaking, vadari reum, among the Romans, was the act of the plaintiff himself, who here demanded suarety, or bail from the defendant, that he would appear before the prætor on a certain day.

VADDAL, in Geography, a town of Hindoostan, in Soonda; 27 miles S.E. of Goa.

VADDER, Louis De, in Biography, an eminent landscape painter, was born at Brüells in 1560. It is not known under whom he studied, where he refixed, or how long he lived; but he has left works behind him which exhibit him as a diligent observer of nature, with taste and feeling to fecile his most fascinating effects, and ability to execute what he attempted, so as to afford the greatest pleasure to all admirers of the art.

It is not improbable that he refixed some time in Italy, and had studied the pictures of Titian; perhaps wrought in the same scenery; for his finest works have a great degree of resemblance to those of the Venetian, in the choice of forms and colour however more than in the execution, in which he more resembles Pynechler in freshness and fulness.

Two large pictures by Vadder found their way into this country some time ago, and fully justify these remarks; but in general his works are scarce, or most probably have been introduced under fictitious names. In his native country he is better known and justly esteemed. He has left a few spirited engravings in the style of Lucas Van Uden.

VADE', John Joseph, was born at Ham, in Picardy, and is distinguished as the inventor of a kind of humorous French poetry. In his youth he refixed at Paris, and led a dissipated life; but in more advanced age he perceived the defects of his early education, and endeavoured to supply them by a perusal of the best French authors. As he was original in his mode of thinking, he adopted a new kind of writing, to which he was led by his familiarity with vulgar life. This species of writing was called the "Poilfaire manner," and he was hence denominated the "Teniers" of poetry. His productions, which consisting of tales and songs, were amusing and popular; and as he possessed many amiable qualities, he was generally beloved in the gay societies which he frequented. But he was thus led to pursue a course of debauchery, which terminated his life in 1577, at the early age of 37 years. His works, consisting of comic operas, parodies, songs, &c. have been collected in 4 vols. 8vo., to which has been added a volume of pothousand pieces of a similar nature, though of superior merit, and indicating talents of a higher class, which he might have cultivated to advantage. Moreri. Nouv. Dict., Hill.

VADELECT. See VALET.

VADE-MECUM, or a VENI-MECUM, a Latin phrase, used in English, to express a thing that is very familiar; and which any one usually carries about with him: it is chiefly applied to some favourite book.

Some make Virgil, others Horace, their vade-mecum; others an Epicetus, &c.

This is what the Greeks call τῶν μηγέθων, or manual. The Arabs have a phrase of equal import; viz. ḥabīl al fa'ir, comes itineræ, companion of the journey. In Latin it is bel expressed by comes; as comes theologicus, comes rufus, &c.

VADENAGORCHY, in Geography, a town of Hindoostan, in Coimbatore; 15 miles W. of Damicottota.

VADIANUS, Joachim, in Biography, was born in 1484, at St. Gall in Switzerland, where his father, Leonard Von Watt, was a senator. Having studied at Vienna, he was chosen professor of the belles lettres, and rector of the university. In 1514 he was honoured at Lintz by the emperor Maximilian with the poetical laurel. In his subsequent travels, he applied to the study of geography, and in 1518, having taken the degree of M.D. at Vienna, he returned to St. Gall, and devoted himself to the practice of physic, to which he joined theology upon the principles of the reformers, whose cause he promoted as a senator, and also by his discourses and writings. Having been honoured eight times with the office of confus, he died in 1551, and bequeathed his library to his fellow-citizens. On the various subjects of mathematics, geography, antiquities, medicine, and theology, he published works, as well as several Latin poems. His "Commentary on Pomponius Mela de Situ Orbis," and his "Scholia on the second Book of Pliny's Natural History," are the most generally known of his literary performances. Scaliger regarded Vadianus as one of the most learned men in Germany; and on account of his able conduct of public affairs, Thuanus presents him to notice, as an example, that men of letters and philosophers are not, as fuch, disqualifed for bufiness. Moreri.

VDATION. See VADARI.

VADICASSES, in Ancient Geography, a people of Gaul, who have been distinguished by different denominations: the Bodicasses of Pliny being the same with the Vadicasses of Ptolomy, and both are supposed to comprehend the ancient inhabitants of Bayeux, anciently called Naronagus.

VADILCORA, or V'adi al Kara, in Geography, a town
town of Arabia, in the province of Hedjes; 56 miles N.
of Medina. N. lat. 25° 30'. E. long. 38° 20'.
VADIMONIS LACUS, in Ancient Geography, a lake of
Italy, in Etruria, in the vicinity of Ameria.
VADIMONIUM, in the Civil Law, a promise, or
bond, given for appearance before the judge upon a day
appointed. See VADARI.
VADIN, in Geography, a town of European Turkey,
in Belcarria, on the Danube; 32 miles W. of Nicepoli.
VADIUM. See GAGE and PONTE per Vadium.
VADNIA, in Ancient Geography, a town of Hither
Spain, belonging to the Cantabri. Ptolomy.
VADO, or VADI, in Geography, a sea-port town of
the Genoese, situated in a bay of the Mediterranean,
with a good harbour; 3 miles S. of Savona. N. lat. 44° 14'.
E. long. 8° 30'.
VADO, II, a town of Naples, in Abruzzo Citra, near
the Adriatic; 16 miles E.S.E. of Larnzano.
VADO SATTA, a town of Naples, in Capitanata; 6 miles
S.E. of Troia.
VADOCONDES, a town of Spain, in old Califile;
26 miles W.S.W. of Olma.
VADORANUM, a town of Hindoostan, in the Car-
natic; 12 miles S. of Nagepaur.
VADUTZ, a town and castle of Germany, in the
principalcy of Lichtenfein; 26 miles S. of Lindan. N.
lat. 47° 5'. E. long. 9° 31'.
VAELEO, a small island in the Baltic, near the north
coast of Lolland. N. lat. 56° 57'. E. long. 10° 46'.
VAELUE, a river of the island of Ceylon, which runs
into the sea, near Mago.
VA-EMBU, in the Materia Medica, a name given by
some authors to the acorus Astaticus, or Astatic sweet
flag.
VAENA, in Geography, a town of Spain, in the pro-
cince of Cordova; 18 miles E.S.E. of Cordova.
VAERO, a small island in the North sea, about 20
leagues from the coast of Norway. N. lat. 67°.
VAESPAA, in Ancient Geography, a town of Asia, in
the Lesser Armenia, towards the mountains, and at a
distance from the Euphrates.
VAG BESTER, in Geography, a town of Hungary, on
the river Waag; 6 miles N.E. of Boelfko.
VAGA, PIERINO DEL, in Biography, whose real name was
Pietro Buonacorfi, was one of those ingenious painters em-
ployed by Raphael to assist him in adorning the Vatican.
He was born at a village near Florence in 1500, of indigent
parents. His father was killed in battle, and his mother
died of the plague before he was two months old. He is
said to have been reared by goat's milk, and as a deftinct
orphan, was taken under the protection of an indiffer-
ent artist named Andrea de Ceri, whose house was frequented
by several young artists of Florence.
As Pierino had discovered a d€sired inclination for paint-
ing, he was placed, when eleven years old, under the tuition
of Roldoso Ghirlandaio, and with his assistance soon became
a very able designer, and more particularly, as Vasari ob-
serves, by studying with many other Florentine youths as
well as strangers the Cartoon of M. Angelo, known by the
name of the Cartoon of Pisa.
His talents acquired for him the attention and approba-
tion of a Florentine painter of inferior quality, but who had
nevertheless much employment, and was in want of a skil-
ful designer to assist him in conducting his undertakings.
With the consent of his guardian Ceri, Pierino accom-
panied this man, whose name was Vaga, to the neighbour-
hood of Rome, whence, when the work was completed which
he had undertaken, he was conveyed by his employer to Rome
in 1515, and there introduced to several painters, to whose
care and assistance Vaga recommended him during his ab-
fence; and thence he was called Pierino del Vaga. In
Rome he endured great miseries, and obtained bread with
difficulty; but ever intent upon improvement, he studied
hard the pictures of Angelo in the Sifini, and designed
from the pieces of antique sculpture which by chance came
to his hand, and after a short time, his ardent exertions
were repaid by a degree of success, which led to his adop-
tion into the school of Raphael.
Julio Romano and Francesco Penni first did justice to his
talents by recommending him to their master, who, upon the
first sight of his productions, placed him under Giovanni da
Udine, who had the management of the ornamental parts of
the works then going on in the Vatican. But Pierino
was soon found equal not only to assist Giovanni in the gro-
tefque ornaments and in the figure, but also Polidoro da
Caravaggio in the antique subjects in chiaro-furo, and
fometime also in executing the figure subjects from the
sketches of Raphael, as among others may be seen, accord-
ing to Vafari, in the Hebrews crossing the river Jordan,
the surrounding Jericho, the combat of Joshua with the
Amorites, Abraham preparing to sacrificing Isaac, Jacob
wrestling with the angel, Joseph and his brethren, &c. &c.
The praise which he gained by these labours inspired him
only with a more earnest desire to improve, and the mildness
and attention of his manner procured for him the esteem
and even love of his master Raphael.
After the death of Raphael, he was employed, with
J. Romano and G. F. Penni, to continue and complete the
adornment of the Vatican, great part of the execution of
which is the work of Del Vaga.
For a short time he went to Florence, where the pope
Leo X. was there, but quickly returned to Rome and per-
fused his labours, adding to them many original ones, the
inventors of his own mind. Among them was the hall of
the house of Machifone Baldaffini, which he adorned with
subjects from the Roman history, with arms, trophies, &c.
Perhaps the most perfect of these minor works was the
birth of Eve, which he painted in the church of S. Mar-
cello, and in which he exhibited his decided predilection
for the style of the Florentine school, and the successes
which he had studied the works of M. Angelo.
Pierino was in full possession of public repute when he
was compelled to fly for safety from Rome, by the factting
of that city in 1527. He took refuge in Genoa, where he
was graciously received by prince Doria, who at that time
projected the embellishment of his superb palace near the
gate of St. Thomas. He had here a full opportunity of
displaying his imagination, as well as his executive powers;
and here he indulged in those inventions which breathe the
spirit of Raphael himself, and rival the exertions of his
fellow pupil J. Romano, in the palazzo del T. at Mantua:
both do honour to the school they had studied in, and the
patron who employed them. He is said not to have been
sufficiently ferulous in the choice of his coadjutors, and
the grandeur of his designs is consequently weakened by
their imperfect execution. He died at Rome in 1547, aged 47.
VAGA, Tagadempt or Swamma, in Ancient Geography, a
town of Africa, in Mauritania Cufarifns, E. of Cirta.
Ptolomy. This town, named Bagza by Plutarch, was
situated S.E. of Victoria. It was one of the episcopal
sees of Numidia.
VAGA, in Geography, a river of Russa, which rises
near Poprovico, in the government of Vologda, and runs
into the Dwina, at Ult Vagikoi, in the government of Archangel.

VAGABOND, a person that wanders about, having no certain dwelling; or a sturdy beggar, &c. mentioned in divers flatutes.

"De vagabundis, et aliis hominibus mendicantis, qui se nominant."—Travelling men, &c. Charta 22 Hen. VI.

All itinerant beggars, fortune-tellers, collectors for goads, fencers, bearwards, players of interludes, minstrels, jugglers, &c. shall be reputed vagabonds, rogues, and sturdy beggars. 39 Eliz. c. 4.

The court of Areopagus at Athens punished idlenees, and exercized a right of examining every citizen in what manner he spent his time. The civil law expelled all sturdy beggars from the city; and, in our own law, all idle persons or vagabonds, (whom our ancient flatutes describe to be "such as wake in the night, and sleep in the day, and haunt customable taverns, and alehouses, and rovs about; and no man wot from whence they come or whither they go;" or such as are more particularly described by flatute 17 Geo. II. c. 5. called the Vagrant Act), and divided into three classes, idle and disorderly persons, rogues and vagabonds, and incorrigible rogues), are offenders against the good order, and blemishes in the government, of any kingdom.

Idle and disorderly persons are thus described by the said flatute: viz. all persons who threaten to run away, and leave their wives or children to the parih: all persons who shall unlawfully return to the parih or place from whence they have been legally removed by order of two justices, without bringing a certificate from the parih or place whereunto they belong; all persons, who, not having where- with to maintain themselves, live idle without employment, and refuse to work for the usual and common wages given to other labours in the like work, in the parishes or places where they live: all persons going about from door to door, or placing themselves in streets, highways, or passagges, to beg or gather alms in the parishes or places where they dwell. And by 32 Geo. III. c. 45. all persons who by their wilful default and neglect permit their wives and children to become chargeable to their parishes or places; and it shall be made appear to two justices that such persons do not use proper means to get employment, or being able to work do neglect to work, or spend their money in alehouses or places of bad repute, or in any other improper manner, and do not employ a proper proportion of the money earned by them towards the maintenance of their wives and families, by which they or any of them become chargeable to such parish or place; and these shall be deemed idle and disorderly persons.

Rogues and vagabonds are, by the same flatute, such as follow: viz. all persons going about as patent-gatherers, or gatherers of alms, under prentence of los by fire, or other cahaulty; persons going about as collectors for prifons, gaols, or hospitals; fencers; bearwards; common players of interludes, and all persons who shall hire for hire, gain, or reward, act, represent, or perform, or caufe to be acted, represented, or performed, any interlude, tragedy, comedy, opera, play, farce, or other entertainment of the flage, or any part therein, not being authorized by law; minstrels; jugglers; and all persons pretending to be gypsys, or wandering in the habit or form of Egyptians; fortune-tellers, or persons pretending to have skill in phsyognomy, palmeiry, or like crafty science, or to tell fortunes; or using any fubtle craft, to deceive and impose on any of his ma- jesty's subjeets; or playing or betting at any unlawful games or plays; all persons who run away, and leave their wives or children, whereby they become chargeable to any parih or place; all petty chapmen, and peddlars, wandering abroad, not being duly licenfed, or otherwise authorized by law; all persons wandering abroad, and lodging in alehouses, barns, out-houses, or in the open air, not giving a good account of themselves; all persons wandering abroad, and begging, pretending to be foldiers, mariners, or feafaring men (but by 43 Geo. III. c. 67, foldiers, sailors, marines, and the wives of foldiers therein mentioned, are relieved against the penalties of the vagrant acts); or pretending to go to work in harvest, without a certificate ligned by the minister, and one of the churchwardens or overseers where he shall inhabit, that he hath a dwelling-house or place there; illegally dealing in lottery tickets and shares; persons to the number of two or more asfailing to defory game in the night-time (39 & 40 Geo. III. c. 50.); and all other persons wandering abroad and begging, shall be deemed rogues and vagabonds. By 23 Geo. III. c. 88. any person apprehended, having upon him any picklock key, crow, jack, bit, or other implement, with an intent feloniously to break and enter into any dwelling-howe, warehouse, coach-howe, flable, or oul-howe, or who shall have upon him any piftol, hanger, cutlifes, bladegeon, or other offensive weapon, with intent feloniously to affault any person; or shall be found in or upon any dwelling-howe, warehouse, coach-howe, flable, or oul-howe, or in any in- closed yard or gardin, or area belonging to any house, with intent to steal any goods or chattles, shall be deemed rogue and vagabond within the meaning of the flatute of the 17 Geo. II. So also by 39 & 40 Geo. III. c. 87. suspected persons and reputed thieves frequenting the Thames, and the quays and warehoues, &c. adjoining, with a felonious intent.

Incorrigible rogues are by 17 Geo. II. c. 5. thus described: all end-gatherers offending against the flatute of 13 Geo. I. being convicted of such offence, which offence, by 13 Geo. I. c. 25. is this, viz. the collecting, buying, receiving, or carrying away any ends of yarn, wefts, thrums, short yarn, or any refufe of cloth, drugget, or other woollen goods; and the punishment of such persons is in order to prevent their committing abuses, by such practices, in the woolen manufaacture: all persons apprehended as rogues and vagabonds, and escaped from the persons apprehending them; or refusing to go before a justice; or to be examined on oath before such justice; or refusing to be conveyed by such pafs as is hereinafter directed; or knowingly giving a false account of themselves on such examination, after warning given them of their punishment: all rogues or vagabonds who shall break or escape out of any house of correction, before the expiration of the term for which they were committed or ordered to be confined by this act: all persons who, after having been punished as rogues and vagabonds, and discharged, shall again commit any of the said offences: all these shall be deemed incorrigible rogues. To which may be added, any person convicted of a third offence against the 6 Geo. III. c. 48.

Idle and disorderly persons are punishable by the flatute 17 Geo. II. c. 5. with one month's imprisonment in the house of correction, upon conviction before one justice, by his own view, confession, or oath of one witnes. Any person...
VAGABOND.

perfon may apprehend or carry before a justice any such perfon, going about from door to door, or placing themselves in streets, highways, or passages, to beg alms in the parishes or places where they dwell; and if they shall refi, or escape from the perfon apprehending them, they shall be puni- sioned as rogues and vagabonds. The reward for appre-
hension is 5s., to be paid under order of the justice, by any overfeer where such offender shall be apprehended.

Rogues and vagabonds are to be apprehended by a con-
table, or any other perfon, and conveyed to a justice of the peace. The reward for apprehending is 10s., by order of the justice, payable by the high offender, or, in case of no high offender, by the petty offender; and on refusal, the justice may by his warrant levy the sum of 20s. by dif-
trefs and sale of the conftable’s goods, &c. (17 Geo. II. c. 5.) But the justice shall not order the reward to be paid until the rogue or vagabond be publicly whipped (women excepted), or sent to the house of correction, and till the examination required by the said act shall be actually tran-
smitted to the next feffions. (32 Geo. III. c. 45.)

The penalty for not apprehending such offender shall be, on con-
viction before one justice, or view or oath of one witness, a forfeitur of 10s. to the poor by dif-
trees. The justices, or any two of them, shall, four times a year at least, order by warrant search for and apprehension of rogues and vaga-
bonds. (17 Geo. II. c. 5.) And by 25 Geo. II. c. 36.
two justices may examine perfo ns apprehended on a pri
vacy on oath as to their settlement and means of living;
and upon their failure of shewing that they have a lawful way of getting a livelihood, or of procuring some responsible housekeeper to testify to their character, and to give securitv (if required) for their future appearances, the justices may commit them to some prison or house of cor-
rection, for any time not exceeding six days, and order the overfeers of the poor to advertise and describe them, &c.; and if no acception shall be laid against them, they shall be discharged, or otherwise dealt with according to law.

After examination by a justice, such justice shall order the offender apprehended to be publicly whipped by the con-
table, petty offender, or some other perfon appointed by them, or order him to be sent to the common gaol (27 Geo. III. c. 11.), or house of correction, till the next feffions, or for any les time (such time not being less than seven days, 32 Geo. III. c. 45.) as such justice shall think proper.—N.B. It is only here expressed generally, that he shall be publicly whipped; the form of the punishment may perhaps be well collected from the provisions of former vagrant acts. By the 22 Hen. VIII. c. 12, the vagrant was to be carried to some market-town or other place, and there tied to the end of a cart naked, and beaten with whips throughout such market-town or other place, till his body should be bloody by reason of such whipping. By the 39 Eliz. c. 4. he was to be stripped naked from the middle upwards, and only whipped till his body should be bloody.

The justices of the next seffions, after commitment of the offender, may, after examination, order a rogue or vaga-
bond to be detained in the house of correction to hard labour, for any further time not exceeding six months, and an incorrigible rogue for any further time not exceeding two years, nor less than six months; and during the time of con-
finement, to be whipped in such manner, and at such times and place, as they shall think fit. Such perfon may, if the seftion think convenient, afterwards be sent away by a pafs; and if such perfon, being a male, is above the age of twelve years, the court may, before he is discharged from the house of correction, send him to be employed in his majesty’s service by sea or land; and if such incorrigible rogue, for or-
dered by the seftions to be detained in the house of correction, shall break out or make his escape, or shall offend again in like manner, he shall be guilty of felony, and be transported for seven years. 17 Geo. II. c. 5.

By 13 & 14 Car. II. c. 12. the justices in seftions may transport such rogues, vagabonds, and sturdy beggars, as shall be duly convicted, and adjudged to be incorrigible.

By 17 Geo. II. c. 5. if the child of any vagrant, above the age of seven years, shall be committed to the house of correction, the justices in seftions, if they see convenient, at any time before such child be discharged, may order such child to be placed out as a servant or apprentice to any per-
son who is willing to take such child, till such child shall be of the age of 21 years, or for a less time; and if any of-
offender, who was found wandering with such child, shall be again found with the same child which was so placed out, he shall be deemed an incorrigible rogue. Where any vagrants have been committed to the house of correction till the next seftions, if, on examination of such perfo ns, no place can be found to which they may be conveyed, the seftions shall order them to be detained and employed in the house of correction, until they can provide for themselves, or until the justices in seftions can place them in some lawful calling, as servants, apprentices, folder s, mariners, or otherwife, either within this realm, or in the plantations in America.

After such whipping or confinement as aforesaid, the justice may, if he think convenient, by a pafs under hand and seal, cause the offender to be conveyed to the place of his last legal settlement; but if it cannot be found, then to the place of his birth; or if he be under the age of 14 years, and have any father or mother living, then to the place of the abode of such father or mother, there to be delivered to some churchwarden or overfeer. 17 Geo. II. c. 5.

And it shall be certified in the pafs, that such perfon has been actually publicly whipped, or confined in the house of correction as aforesaid. 32 Geo. III. c. 45.

The justice shall make a duplicate of the pafs and ex-
amination, and sign the same; and shall afterwards transmi-
t the duplicate of the pafs, annexed to the examination, to the next seftions, there to be filed and kept on record; and shall annex the duplicate of the examination to the pats, and fend it with the same; and the said pats, examination and duplic-
t of the same, shall and may be read in any court of record as evidence. 17 Geo. II. c. 5.

And the justice who shall make the pats shall with the pats cause likewise to be delivered to the conftable a note or certificate, ascertaining how they are to be conveyed, by horse, cart, or on foot, and what allowance such conftable is to have for conveying them. The conftable who shall receive such pats and certificate, shall convey the perfon ac-
cording to the direction of the pats, the next direct way to the place whither he is ordered to be sent, if it be in the same county, riding, division, corporation, or franchis; if not, he shall deliver the said perfon to the conftable of the first town, par 
ishes, or place, in the next county, riding, division, corporation, or franchis, in the direct way to the place whither he is to be conveyed, together with the pats and duplicate of the examination, taking his receipt for the same.

And such conftable shall, without delay, apply to some justice in the same county or division, who shall make the like certificate, and deliver it to the conftable, who shall with all speed convey such perfon unto the first parish town or place in the next county or division, in the direct way to the place to which he is to be conveyed; and so from one county or division to another, till they come to the place to which such perfon is sent. And the conftable, who shall deliver
deliver such person to the churchwarden or other person ordered to receive him, shall at the same time deliver the said pass, with the duplicate of the examination, taking their receipt for the same. And whereas the present mode of conveying vagrants in the custody of a constable is frequently insufficient, it is enacted, that the justices in seances may order that all rogues and vagabonds apprehended within their liberties, and ordered to be conveyed by pass, shall be conveyed by the master of the house of correction, or his servants, or by a constable, as they shall think proper; and they may make an order, that all constables, to whom rogues and vagabonds brought from another county are delivered, shall forthwith convey them to the nearest house of correction or within their liberty, to be afterwards removed by such master or his servants as aforesaid, and according to the provisions of the aforesaid act. 32 Geo. III. c. 45.

The passing of vagrants may be suspended on account of sickness by 35 Geo. III. c. 101.

By 49 Geo. III. c. 124. it is enacted, that in all cases whenever the execution of any order of removal, or of any vagrant-pass, shall be suspended by virtue of the 35 Geo. III. c. 101. any other justice of the peace of the county, or other jurisdiction within which such removal or pass shall be made, may direct and order the same to be executed, and the charges incurred to be paid, and may carry into execution any such amended orders, as fully as the same can be done by the justices who shall make the order of removal, or the justice who shall grant the pass.

Any justice before whom a vagrant shall be carried may order him to be searched, and his bundles to be inspected, by the constable or other officer in his presence; and if it shall appear that such vagrant shall be found to have sufficient wherewithal to pay for his passage, either in whole or in part, the justice shall order so much of the money to be paid, or other effects found upon such vagrant to be sold, and employed towards the expenses of taking up and passing such vagrant, returning the surplus, after deducting the charges of such sale. 17 Geo. II. c. 5.

To defray the expenses of apprehending, conveying, and maintaining rogues, vagabonds, and incorrigible rogues, and defraying all other expenses necessary for the execution of this act not herebefore provided for, the justices in seances may cause such sums as shall be necessary to be raised in the same manner as the general county rate.

Any person aggrieved by any act of any justice out of seances, in or concerning the execution of this act, may appeal to the next general or quarter-seances of the county, riding, liberty, or division, giving reasonable notice thereof; and whole order thereupon shall be final.

Persons fined for any thing done in the execution of this act may plead the general issue; and if they recover, shall have treble costs.

In all cities and towns, where by virtue of special acts of parliament the charge of passing vagrants is to be defrayed in other manner than is by this act directed, or where such vagrants, by virtue of special statutes, are to be apprehended and conveyed by any person or officer, other than those named in this act, the same shall not be altered hereby. And persons conveyed in London, shall not be delivered in any other precinct within the city, but in the next county. 17 Geo. II. c. 5.

VAGAI, in Geography, a river of Ruffia, which runs into the Itirfich, 8 miles S.E. of Tobolok.

VAGAL, in Ancient Geography, a town of Africa, in Mauritania Cufieranis, on the route from Rufucerrum to Catama, between Gadaum Cafta and Caftellum Tingitannum, according to the Itinerary of Antonine.

VAGENI, Bageni, or Vagenni, a people of Italy, in Liguria, towards the sources of the river Eridanus, according to Silius Italicus. Pliny calls them Vagnieni Ligures.

VAGERA, in Geography, a town of Arabia, in the province of Nedjed; 90 miles N.E. of Mecca.

VAGESA, in Mythology, a name of the Hindoo god Siva. He is also called Vagefwara, or the lord Vagefa; sometimes pronounced Bagis, and Bagifwar. His consort Parvati, as his energy or fakti, is named Vageswari. (See PARVATI and SIVA.) In the latter article, it will be seen that some etymologists, from this similarity of name, strengthened by other characteristic coincidences, conceive Bagisa and Bacchus to be names of the same person.

VAGESWARA, a name of the Hindoo god Siva; meaning the lord Vagera, as noticed under that article.

VAGINA,
VAGINA.

VAGINA, a Latin term, literally signifying a Flushed, or \[\text{flabellum}, \text{used on divers occasions}. \]

VAGINA in \textit{Architecture}, is used for the lower part of a termus; because resembling a Flushed, out of which the Flushed seems to issue. \textit{See Terms.}

The Flushed is that long part between the base and the capital; and is formed in divers manners, and with divers ornaments.

VAGINA, in \textit{Anatomy}, the membranous canal leading from the external organs of generation to the neck of the uterus, and receiving the male organ in coitus. \textit{See Generation.}

The Flushed is liable to an inflammation after delivery, occasioned by the head of the child being long retained in the pelvis. If the swelling and inflammation are not very great, they are generally removed by the discharge of the lochia; but if the internal membrane of the Flushed be inflamed, emollient injections must be occasionally used, and a piece of prepared sponge should be introduced, to prevent its coagulating. The sponge may be thus prepared: Take a piece of a proper size for keeping the Flushed open, when it is to be closed, and roll it tight from end to end with a flaring; cut off any hard lumps, and lay it to dry; then take off the flaring, anoint it with lard, and introduce it into the Flushed, the moisture of which will expand it. If the pressure on this part was so long continued, as to obstruct the circulation in it, a mortification will ensue, which may be either total or partial: if it be total, the patient will die; if partial only, the mortified parts will slough off. This may be known by great pain after delivery; a fetid smell, and a discharge of sharp ichor at first from the Flushed, then put and matter. When this is the case, emollient fomentations may be thrown up from time to time; doffils of lint may be dipped in some proper balsam, and applied to the parts in order to detere and heal them; and when the sloughs are all call off, great care should be taken to prevent the Flushed from growing together, either by introducing doffils of lint, or pieces of sponge into it.

VAGINA, Imperforate. The vulva is liable to two different kinds of imperforation, which ought to be differ- minated. First, the labia and ymphæ may be covered where united and blended together, the orifice of the meatus urinarius being totally covered by them, so that no urine can be voided. Secondly, the hymen may form a complete septum, or else some part of the Flushed may be closed with a membrane of similar structure; in which circumstan- tances, although the Flushed be imperforate, there is no impediment to the free issue of the urine.

The first cafe constitutes a species of malformation, at tended with the greatest urgency, and which indeed admits of no delay of that operation by which the conjoint parts are to be separted. The kind of raphe, situated where the natural opening ought to be, should be immediately sought for, and here the requisite division of the parts is to be made, the incisions being carried to the necessary depth, yet always with a cautious hand, left an opening be made into the bladder, or rectum. Concretions of the labia and ymphæ together may be the consequence of ulcerations of these parts; but the closure of the vulva is then never complete. The frequent evacuation of the urine separtes the parts; and, if not capable of preventing their union entirely, it is at least sufficient to maintain an aperture opposite the meatus urinarius. The narrowness of the external opening, however, may obtrude the free discharge of the urine; and urinaiy calculi may even form more or less deeply in the Flushed. Now, without taking into the account other functions of the sexual organs, the motives already explained are quite prehizing enough to make the removal of the de- formity right and advisable.

Before the age of puberty, no inconvenience can arise from the Flushed being completely shut up by the hymen, or some other analogous membrane. But, at this period, the menstrual blood collects first in the Flushed, and then in the uterus. Severe periodic colic pains, of gradual dure- tion of the uterus, the absence of the menses, impairment of the health, a variety of nervous complaints, and some- times even inflammatory symptoms, which recur, or are exacerbated periodically, afford strong presumptive grounds for suspecting an imperforation of the Flushed. More in- formation may be acquired from a careful examination of the parts. In the greater number of instances, the membranous septum is dilated with the menstrual blood, and even sometimes protrudes from the vulva, in the form of a browish, elastic, fluctuating tumour. Almost an immediate flow has been often put to alarming symptoms of long duration, by making an incision through the membrane causing the obstruction. A crucial wound will be sufficient, with the use of a ligature of the membrane away; but we are recommended not to neglect to keep the newly divided parts sunder for a few days, by means of a tent, or a doffil of lint.

Labours are sometimes so difficult, and attended with such injury, that inflammation, and even ulceration of the Flushed, may be thus produced. These effects may be fol- lowed by considerable contractions of this canal, arising from the shrinking of the cicatrices. However, such a case is not what we have now to consider, our remarks being at present restricted to examples in which the Flushed is alto- gether impervious.

The os tinaee may be entirely obliterated by congenital malformation, the effects of difficult labours, or any other circumstances producing inflammation in the part. In all these cafes, menstruation and conception are rendered im- possible, and a train of phenomena is observed, resembling those of the congenital imperforation of the vulva and Flushed. But the os tinaee may become closed, from some accidental cause, subsequently to conception, and then the defect cannot be known until the period of delivery. In this last case, it is highly important to ascertain correctly whether the orifice of the womb is really obliterated; or whether an obliquity of that organ, or some other derangement of it, may not impose upon us?

The re-establishment of the natural opening is always in- difpenable, and it is materially facilitated by the dilated state of the uterus. The operation can be most conveniently done, either with the instrument called a pharyngotomus, or a curved bistoury, which has a cutting edge that extends only a short distance from the point. See Delpech, \textit{Précis Élémentaire des Maladies réputées Chirurgicales}, tom. 1, p. 497, 8vo.

VAGINA, Prolapsus of, denotes, in \textit{Surgery}, a species of \textit{bearing down}, arising from a protrusion or defect of the Flushed. The Flushed is liable to two kinds of prolapsus. In one case, all its tunics are included in the protrusion, and at the same time that the part falls downwards, it be- comes inverted. In the other example, it is only the relaxed lining of the Flushed which defends and makes a protrusion.

The first species of prolapsus Flushed is subject to varieties. For instance, sometimes the whole circumference of the orifice falls down; sometimes only a portion of one of its sides. In the first event, the prolapsus forms a cylindrical tumour, which consists of all the coats of the Flushed, pre- senting an opening at its lower termination, and having an external covering, which is composed of the internal lining.
of the vagina. But when the protrusion comprehends only a portion of one of the sides of this tube, the tumour occurs in the form of a cul-de-sac, which can be put back into the vagina with the finger or probe, and the lower end of which is without any aperture. The following differences are also remarkable in cases where the lining of the vagina constitutes the prolapsus. In some instances, the lining of the whole circumference of the part protrudes in the form of a cylindrical swelling, confining of a duplication of that coat. In other examples, the membrane lining the vagina is relaxed and elongated only at one or more particular points, and produces one or more external swellings of the cul-de-sac figure. This last case is liable to be mistaken for polypi of the vagina.

The possibility of a prolapsus of the whole of the vagina, together with all its coats, has been doubted by Sabatier and Levret; but, as Richter conceives, without any real foundation. If, as the latter author observes, it is the inner coat of the vagina to separate from the external with which it is intimately connected, an event which every body admits as happening in the second kind of prolapsus vaginae, why should it be impossible for the whole of this tube, together with all its coats, to be separated from the surrounding parts, to which it is not so closely adherent? Sometimes the rectum, inclusive of all its coats, forms what is termed a prolapsus ani, and why may not the vagina be displaced in a similar manner, since it must be much more liable than the rectum to be propelled downwards in the violent straining which takes place during parturition? Richter asks, whether every prolapsus uteri is not accompanied with such a displacement of the vagina? Cashes are upon record, where the prolapsus of the vagina happened all on a sudden, in consequence of falls, the slipping of a horse, &c. (Hoin, Levret, Journal de Médecine, tom. xl.) Here it cannot be supposed, that the cafe was merely a protrusion of the inner coat, which can only be gradually relaxed and elongated. Lastly, instances in which the prolapsus of the vagina was several inches in length, have been gradually reduced by the use of external pressure. (Hoin.) How can we imagine, says Richter, that such cases could proceed from any degree of relaxation, to which the membranous lining of the vagina is liable?

It must be acknowledged, however, that this species of prolapsus is much less common than the second kind; that when it occurs, it is generally as a consequence of a prolapsus of the uterus; and that it cannot easily happen at all, except about the time of delivery. A prolapsus of the inner coat principally occurs in married women who have had many children, and been frequently troubled with flor albus. It has, however, been occasionally met with in young unmarried females. The prolapsus of a particular portion of the inner coat of the vagina, is generally the consequence of a hernia in this part; but sometimes in cases of filepity, a portion of the vagina, containing fluid, protrudes in the form of a cyst, or faec.

When the whole circumference of all the coats is involved in the prolapsus, if a finger, or probe, be introduced into the cylindrical tumour, which the patient is convinced has been found to be situated closely behind the external pudenda; for this sort of bearing down is always attended with a displacement of the womb, in the direction downwards. In many instances, particularly when the prolapsus has taken place suddenly, and is quite recent, the patient experiences a variety of complaints about the bladder and rectum, and the evacuation of the urine and faces becomes more or less interrupted. That the protrusion comprehends all the coats of the vagina, is frequently quite manifest from the thickens of the cylinder. Also, when the accident has occurred suddenly, or it can be easily reduced; there is always reason to conclude that the prolapsus is of the preceding description.

The prolapsus of the inner membrane of the vagina generally arises gradually, and often as a consequence of a long continued flux albus. It either does not admit of reduction, or, if reduced, it lies in the vagina, and fills its cavity. It has very little effect upon the uterus itself, which usually remains in its natural position, and it seldom produces any difficulty in the evacuation of the urine and faces. When only a part of one side of the inner membrane of the vagina is relaxed, elongated, and protruded, the swelling can be pushed back into the vagina with the finger, and thus the nature of the complaint becomes manifest. The prolapsus, arising from a hernia in the vagina, can only be ascertained by attending to the symptoms which characterize this sort of rupture, and which are noticed in the article Hernia.

A prolapsus of all the coats of the vagina, while it is small and recent, can be reduced by pressure without difficulty. But the thing which demands the greatest care, is to hinder a relapse. This is accomplished by the employment of a pessary, and the use of astringent applications.

When, however, the last species of prolapsus has exlicted a long while, its reduction is more difficult; for the vagina, after it has remained displaced a certain time, begins to be affected with swelling and induration. According to the reports of Hoin and Levret, a large protrusion of this kind, ten inches in length, was so diminished by keeping the patient in variably confined upon her back, that in the course of a month the rect of the tumour admitted of being reduced. Indeed, as Richter observes, there can be little doubt, that the treatment which has been advised by some authors for the diminution of very old enormous omental ruptures, would here be equally applicable; viz. long confinement in bed upon the back, with the buttocks somewhat elevated; continued, well-directed, external pressure; a very low diet, and repeated mercurial irrigations. By such means, no doubt, the swelling might be in many instances sufficiently lessened to admit of reduction.

During the state of pregnancy, a prolapsus of the fore coming kind may be attended with considerable embarrassment, and even danger. In one case, where such a prolapsus, five inches in length, took place during labour, it became necessary to turn the child, and the displaced vagina was also lacerated. The woman, however, recovered. (Pitich, Journal de Médecine, tom. xxxiv.) In another case, where the prolapsus became as large as a man’s head at every return of the labour-pains, the practitioner succeeded in holding the parts back, while the woman was delivered with the aid of the forceps. (See Loder’s Journal, 1 b. p. 450.) When this is impracticable, it is necessary, according to Richter, to make an incision through both sides of the prolapsus; a proceeding, lays he, to which the practitioner may the more readily make up his mind, inasmuch as the parts have even been lacerated, without any ill consequences, as we have already related.

The prolapsus of the inner membrane of the vagina, while small and recent, may perhaps be removed by astringent applications. When, however, it is of long standing, indurated, and of large size, much expectation of succour from this treatment cannot be entertained. Richter fees no reason why, in such a case, the redundant relaxed part should not be cut away, especially when the disea is accompanied with ulceration, and other serious complaints. As he observes, there can be no doubt that a prolapsus of the inner membrane of the vagina, when limited to one part of this
VAG

this canal, may always be safely extirpated either with a knife or a ligature. Richter's Anfanggr. der Wundarzney-
kunst, b. 7. Vierte Kapitel.

VAGINÆ. Femoris Tendo, in Anatomy, a name given by Albinius to a muscle in the thigh, called by others the mem-
branous, and the myotus fascia late; and by some myotus APONEUROTICUS, which see.

VAGINÆ. Uteri Splintier. See Generation.

VAGINA Poliærum, in Botany and Vegetable Phylology, the sheath of the leaves, (see Leaf and Sheath,) most peculiarly observable in grages, and their allies, confines of that part of the leaf which is below the stipula, by which it is crowned. The Vagina embraces the stem, or fraw, more or fefs closely. Its inside is usuallly quite smooth, and polished, while the outside is generally ribbed, rough, or hairy, though commonly less so than the leaf itself. The pubescence in some instances is directed contrariwise to that of the leaf. In molt grages, particularly the corn tribe, the sheaths of one or two of the uppermost leaves are much diluted, serving the important purpose of protection to the young panicle or spike of flowers. A singular theory respecting the cause of fmut in grain was, many years since, published by the Rev. Henry Bryant, of Hempf, Norfolk. (See SMUT.) The minutest was, by this writer, attributed to an accidental tightness in the summit of the sheath of the leaf, by which the young ear was, in a manner, strangled; an hypothesis totally insufficient to account for the phenom-

The term vagina is, in like manner, applied to the lower part of the foliage of the Crocus, the Snow-drop, and various other plant's leaves related to one or the other, in which the leaf tapers down into a sort of sheathing footstalk. But it is erroneously exemplified by professor Willdenow, in his Principles of Botany, by the genus Polygonum, whose cylin-
drical membrane, attached to the inner side of each foot-
stalk, and surrounding the stem above every joint, is a real sheathing Stiplua, fle that term; the footstalk being in-
terposed between it and the leaf. So in Spermacetes, and other plants of the extensive and various order of Rubiaceae, the membranous intratefilaceous stipula must not be taken for a vagina, though it be connected, ever so closely, with the footstalks at each side; because the analogy of molt plants of that order shew it to be a real stipula, which from its fitution, and the varieties in its fform, structure and afpact, is of peculiar botanical importance.

VAGINALIS GUL., in Anatomy, the mucular flâma-
tum surrounding the mucous membrane of the esophagus. See DEGLUTITION.

VAGINALIS IT}}, the serous membrane surroun-
ding the tefticle, and forming the bag, in which it is included. There is also a covering, composed of condensed cellular membrane and the fibres of the cremalfer, which surrounds the spermatic cord and the testis with its membranes. This is called tunica vaginalis communis. See GENERATION.

VAGINALIS, in Ornithology, a genus of the order Gralla of birds, of which there is one species, var. the V. alba, or white sheath-bill of Latham. Found in New Zealand, and other islands of the Southern ocean.

VAGINARIA, in Botany, named from vagina, a sheath; because the ftem is clothed with leafless sheaths. Pursh 58. This genus is adopted by Pursh from Perfonn, and its distinctive character confines in the seed being surroun-
ded at the base with three scales, and three intermediate brilles. One or the other of these parts doublefs origen-
ates in the three flamen. The fignum, moreover, are faid to be three.

The only species mentioned by Pursh is V. Richardi.
V A N

"Alma parents Indica deum, cui Dindyma cordi,
Turrigerneque urbes, bijugique ad frerna leones."

Dryden changes her lions into tigers.

"Hear thou great mother of the deities,
With turrets crowned, on Ida's holy hill,
Fierce tigers reined and curbed obey thy will."

Pitt, however, in his invocation, restores the tigers.

"Great guardian queen of Ida's hills and woods,
Supreme, majestic mother of the gods!
Whose strong defence proud tow'ring cities share,
While roaring lions whirr thy mighty car."

In most languages of the East, it may be observed, the same word means both lion and tiger. The Greeks or Romans, borrowing the attribute from the East, may easily have misconceived its name. (See Cybele and Parvati.) It might be shown that most of the mystical ceremonies practised by the Welfern heathens in honour of the goddess Cybele, were, and are, common also in India in honour of Parvati. The peacock is likewise sacred to the latter, and is, as we shall presently notice, the vahan of one of her family, Kartikya, otherwise called Komara; and the being deemed his fakti is called Kaumari, and is likewise so conveyed.

Having thus seen that the vehicles of the three great powers composing the Hindoo triad are severally the fawn, the eagle, and the bull, we proceed to notice how the inferior deities are accommodated.

Surya, or the sun, rides sometimes a lion, but generally in a golden car drawn by seven tigers, or by one horse with seven heads. The horse is sometimes named Ochiferova (which fee); but we are in some doubt if correctly. Soma, the moon, is drawn in his Evil car (the moon is mackulline in India) by an antelope. Pavaka, the god of fire, rides an ardent ram. Kama, the Indian Cupid, rides a luri, or parrot. Varuna, genius of the waters, beholds a fish, as does also Ganga, the Ganges, primal goddes of rivers. Ganja, the god of prudence and policy, has an elephant as his vahan, it being supposed the animal of greatest foresight: a rat is also deemed a very sagacious animal, and Ganja is sometimes seen so mounted. He is reputed the eldest son of Parvati, and is otherwise named Polkar; which see. Kartikya, her second son, or rather her lord's son, is borne by a peacock, as before noticed. Indra, regent of the firmament, has a three-trunked elephant, named Iravat. Pavaka, a son of Siva, rides a buffalo, sometimes a dog. Vayagravati, and Vrishnidevati, are names of Parvati and Siva, meaning tiger-mounted, and one who rides a bull.

Ailroglers have mounted the reft of the planets, as well as the sun and moon. Mangala, or Mars, on a horse, sometimes on a ram: his fiery nature connects him sometimes with the igneous Pavana, who rides the latter animal. Boodeh, or Mercury, being by some accounts a manifestation of Vishnu, at any rate bearing the name with a disputed avatar or incarnation of that god, shares his vehicle, and the planet is mounted on an eagle. Vrishniraji, or Jupiter, on a boar. Sakra, or Venus, on a rat, sometimes on a camel. The flow'ring Sanee, or Saturn, on the heavy elephant, or ill-omened raven. Rahu, the dragon's head, on a tortoise or owl: and Kebu, the tail or descending node, on a frog.

The word vahan is usually pronounced as one broad syllable; and it has been surmised that the English van and sain may bear some etymological affinity to it.

VAHARA, in Geography, a town of Arabia Deferta; 150 miles W. of Jamama.

VAHINGEN. See Vathingen.
coloured plates, not highly finished, but expressive and correct. The principal object of this work was, in the first instance, to illustrate Forckell's discoveries, very incorrectly displayed in his own pompous Flora; and the materials for the exemplification of which are, it seems, but partially and imperfectly preferred. Vahl's Symbols are moreover enriched with descriptions and figures of new or rare plants, from various other sources. The communications of the author's numerous correspondents, particularly of Von Rohr and others from the Danish West Indian colonies, are added to the acquisitions of his own journeys; and the whole forms a large body of valuable practical information. His Elogio Americana, published in 1796, are a sequel to the Symbols, on the same plan, but devoted to American plants.

In 1799 and 1800 professor Vahl received the pecuniary support of the Danish government in a second tour to Holland and Paris, for botanical purposes; chiefly, we presume, with a view to the composition of a great work, long in his contemplation, on the model of the Linnaean Species Plantarum. Of this he just lived to publish the first volume, under the title of Enumeratio Plantarum, in 1804, in 8vo, including the classes Monandria and Diandria. The second, containing only the Triandria Monogynia, was published by his widow in 1805. The copious introduction of new species, the ample original descriptions of the well-known families, and the judicious remarks, render this work far superior to any other of its kind, giving it all the merit of an original performance. Besides the addition of the essential generic characters, as in the Systema Vegetabilium of Linnaeus, Vahl's Enumeratio is enriched with a copious description of the peculiar habit of each genus, after a plan first introduced by Gouan, in his Flora, as well as Hortus Monspeliensis, and which Linnaeus justly commended, as leading the way to improvement in natural classification. Nor must we pass by, without commendation, the excellent generic and specific index to each volume, an appendage of whose value we are seldom duly sensible, but from its inaccuracy or omission in other inferences. The neglect, or bad construction, of indexes, and the omission of references to pages, are defects of the modern French school, which may be avoided by any botanical writer, even of the most humble scientific pretensions, and which the most learned ought not to neglect. The sequel of professor Vahl's last publication, as far as concursus gralliæ, was reported to have been left by its author in considerable forwardness, and was, if we mistake not, announced for publication. Something to this effect is found in the preface to the second volume; but we know not that any part of these valuable materials has appeared. The botanical professorship at Copenhagen was conferred on Mr. Vahl, after his return from his second visit to France, but he lived not long to enjoy his well-merited fame and distinction. He died on the 24th of December, 1804, in the 54th year of his age, leaving a widow and six children. His library, herbarium, and manuscripts were purchased by the king of Denmark for 3000 dollars, about 675l., besides an annual pension of 400 dollars, or 96l., to his widow, and of 100 dollars to each of his children. It was intended that the above-mentioned manuscripts, including a finished treatise on the class Syngenesia, should be edited by the successor of professor Vahl, Mr. Horneuman, to whom the continuation of the Flora Danica was likewise confided. We are not informed of the progress of either.

Besides the botanical writings of professor Vahl, he has published some zoological papers in the Danish language, especially relating to birds; and has described a fish, constituting a new genus, by the name of Holocentrus lenticigerous, in the third volume of the Transactions of the Natural History Society of Copenhagen.—A more detailed review than we could here undertake, of the first volume of the Enumeratio Plantarum, may be seen in Sims and Konig's excellent Annals of Botany, v. 2. 179, where Mr. Konig has noticed every new article of information, and corrected every incidental mistake, with commendable accuracy and knowledge. We have already advanced an opinion similar to that of this able critic, respecting Vahl's removal of the Linnaean Species Plantarum, fee that article, from the class Monandria to Gynandria; a measure barely to be excused by our supposition, and not at all to be justified by any alleged reason.—Vahl's Works. Sims and Konig's Ann. of Bot. v. 1 and 2.

VAHLIA, in Botany, received that name from Thunberg, in honour of his contemporary professor Vahl. (See the last article.) The same genus was originally defined by the great Linneaus to commemorate Jean Jacques Rousseau, as appears by specimens in the Linnaean herbarium, marked Roffa capensis; but he did not live to publish this genus, which his son, through inadvertence probably, introduced into the Supplementum Plantarum, by the name of Russellia, that fee article and Rousseau. Those names being otherwise appropriated, the Vahlia is finally establisht.—Thunb. Nov. Gen. 36. Schreb. 176. Wild. Sp. Pl. v. 1. 1534. Mart. Mill. Diet. v. 4. Julii. 318. Lamarck Histoire t. 135. (Rufella; Linn. Suppl. 24. Murr. in Linn. Syrf. Veg. 14. 1796.—Clafs notor. Pentandria Dizygia. Nat. Ord. Calycantheme, Linn. Onger, Joff. Gen. Ch. Cal. Partheni superior, of five lanceolate, acute, concave, spreading, permanent leaves. Cor. Petals five, ovate, concave, spreading, undivided, not half so long as the calyx. Stam. Filaments five, inserted into the calyx between the petals, and full as long as its leaves, thread-shaped, erect; anthers incumbent, oblong, with four furrows. Pijf. Germen inferior, roundish; styles two, thread-shaped, slightly spreading, longer than the flaments, stigmas fimple, obtuse. Perc. Capsule ovate, abrupt, marked with five elevated lines, and crowned with the calyx, of one cell and two valves. Seeds numerous, minute.

Eff. Ch. Calyx of five leaves. Petals five, alternate with the flaments. Capsule inferior, of one cell and two valves, crowned with the permanent calyx. Seeds numerous.

X. V. capensis. Cape Vahlia. —Thunb. Nov. Gen. 36, with a plate. Prod. 48. Wild. v. 1. (Rufella capensis; Linn. Suppl. 175.)—Gathered by Thunberg, in sandy ground, near the valley of Verkeerden, at the Cape of Good Hope, flowering in December. It has not yet been brought to England. The root is woody and perennial. Stems several, herbaceous, erect, a span or more in height, simple or branched, leafy, clothed with short, soft, prominent, vilose pubescence, like all the rest of the herbage. Leaves opposite, fifele, linear-lanceolate, entire, pale green, an inch or inch and half long. Flowers yellow, in small, axillary, nearly fifele, tufts, about the upper part of the branches, accompanied by a small lanceolate bracteæ. The petals and filaments assume a violet hue when dried.

VAHNI, in Mythology, a name of the Hindu regent of fire, who is more commonly called Pariaksha; which see. A similar name, usually indeed written Vini, is given to Sarawari, confort of Brahmu. See SARAWANI and MARUT.

VAIDYA, the name of a respectable class of Hindous, who follow the profession of physicians. Individuals of different religious sects are comprised in this denomination. (See SIVIT of Hindus.) Sir W. Jones, speaking of the Vaidyas, says, "they have more learning, with far less pride, than any of the Brahmins: they are usually poets, grammarians, rhetoricians, and moralists; and may be esteemed, in general, as the most virtuous and amiable of the Hindous."
VAIGAL, in Geography, a town of Hindoostan, in Golconda; 20 miles S.S.E. of Comonbat.

VAIGAR, an island of Russia, in the Frozen ocean, on the N. side of the straits of Vaigatskoi, about 24 miles in length, and about 8 broad. N. lat. 75° 30'. E. long. 52° 24'.

VAIGATSKOL, PROLV, or Straits of Vaigate, between Nova Zembla, and the continent of Russia.

VAIGA, a town of France, in the department of the Mayenne; 12 miles E. of Laval.

VAIHEND, or SCANDERBE, a town of Perânia, in the province of Segesta, anciently Alexandria; 50 miles E. of Arokhaie. N. lat. 31° 10'. E. long. 60° 40'.

VAI-HIO, in the Materi Medica, a name used by some authors for a kind of lignum aloes, which is brought from China, and is very black, and scented.

VAIJAYANTJA, the name of a palace of the Hindoo god Indra, situated in a celestial city named Amrovatia. (See Indra.) Another of his abodes is called Sitanta; which see. See also VAIKONTHA.

VAIKONTHA, the paradise of the Hindoo god Vishnu. It does not precisely appear whether this abode is celestial, terrestrial, or subterranean. Sometimes it is described rather of the latter sort in a sea of milk, called Kirrafamudra, where Vishnu is pictured reposing on a mighty serpent named Sehsa, accompanied by his delightful confont Lakshmi. (See Lakshmi and Sesha.) A commentator on a Sanscrit work entitled Kthre Nrmana, the most ancient perhaps of Hindoo geographical books, places Vaikontha in the Frozen ocean: a circumstance that would have afforded curious confirmation to an idea of Buffon and Bailie as to the site of Eden, had these eminent men been aware of it: an idea more ancient, indeed, than the day of these philosophers, as Pottellus had a familiar notion. See Paradise.

Several of the Hindoo deities have refidences especially assigned them, by European writers usually called the paradise of those deities respectively; thus Indra's abode is called Sitanta, Svarga, and Vaayayanta; that of Siva, Kiiafa; that of Varuna is Subhallati. Generally, these palaces or places of the Hindoo gods are described as situated on a mythical trufurcated hill named Meru, to which word we refer the reader for some of the extravaganzas connected with the Olympa of the Hindoos.

VAILATA, in Geography, a town of Italy, in the department of the Adda; 18 miles E. of Milan.

VAILAC, a town of France, in the department of the Lot; 15 miles N. of Cahors.

VAILLANT, JEAN FOI, in Biography, an eminent antiquary and medallist, was born at Beauvais, in Picardy, in the year 1632. His maternal uncle, to whose care his education was entrusted, designed him for the profession of the law; but inheriting the fortune of this relation, he devoted himself to the study of physics, in which faculty he took a degree. Having accidentally gained possession of a box of medals, he relinquished his medical pursuits, applied to anciennarian and medallic researches, and soon formed a valuable cabinet, to the ineracle of which his various travels very much contributed. In one of his excursions for this purpose, he was attacked by an Algerine corsair and carried into slavery; and after his release, he was on another occasion attacked by a Tunisian; and in order to secure fifteen or twenty gold medals which he had in his possession, he swallowed them, and in process of time nature relieved him of his burden, which he disposed of to an amateur with advantage.

On his return to Paris, he distinguished himself by various dissertations on medals. He was thus recommended to the court, and employed on a commission for the protection of the same objeet. His ardour urged him to visit Egypt and Perânia, and he was recompened by obtaining a rich cargo of medals. To the memoirs of the Academy of Insigniferences and Belles Lettres, of which he was a member, he communicated several valuable papers on his favourite subjeet: his reputation gained him the post of keeper of the duke of Maine's cabinet of medals; and even at Rome he was so highly esteemed, that he obtained a dispensation from the pope to marry successively two sisters. His private character was highly estimable. His labours were terminated by death in 1706, at the age of seventy-four years. The titles of some of his principal works, independently of several separate dissertations, tending to illustrate medallic science in its connection with history, are as follow: "Numismata Imperatorum Romanorum," 1674–40, of which an enlarged edition was published by Baldini at Rome in 3 vols. 4to. 1743; "Sceurcadarium Imperium, five Historia Regum Syrie ad fimem Numismatum accommodata," 1681, 4to. "Seleclata Numismata Antiqua ex Musco Petrse Seguini," 1681, 4to. "Numismata Erea Imperatorum, Augusturum et Cesarum in Colonii, Municipiis, &c." 2 vols. fol. 1680; "Numismata Imperatorum, &c. Grceca," 1698, 4to. "Hitoria Tolomeorum Egyptiae Regnum ad fimem Numismatum &c." 1725, 4to. "Achæmenidarium Imperium, &c." 1725.

The son of the preceding, viz., JOHN-FRANCIS FOI,

VAILANT, born at Rome in 1665, was instructed by his father in medallic science, and was graduated for the profession of physici. He published several dissertations on medals in the Memoirs of the Academy of Insigniferences, of which he was a member, and also a dissertation on the "Die Cabiri." His life terminated in 1708, in the 44th year of his age. Morer.

VAIEILANT, SEBASTIAIN, a distinguished French botanist in the early part of the 18th century, was born May 26th, 1669, at Vigny, near Pontoise, being the eldest son of a shopkeeper in that town. He is described as having, like many other botanists of eminence, imbibed a taste for plants at a very early age, and even before his sixteenth year to have cultivated, in a little garden of his own, with which his father indulged him, all the plants he could collect from the country around, or from the gardens of his neighbours. We can hardly wonder that his illustrious biographer Boerhaave, should, as a physician, delight also to record an instance of Vaillant's early medical talents, in curing himself clandestinely of an intermittent fever, with]
when he removed to Evreux in Normandy, to place himself under another surgical teacher. Here he gained the good opinion of the marquis De Gouvill, captain of the royal fulfliers; who engaged M. Vaillant as surgeon to his company, with the rank of lieutenant. Thus the peaceable botanist, the organist of a nunnery, became a soldier; encountered the dangers of a campaign; came off with honour and safety; performed the last duties to his patron, who fell in the battle of Fleurus, July 1, 1790; and after visiting several towns in Flanders, returned to Evreux, which he quitting next year to pursue his studies, with more advantage, at Paris.

On the theatre of the metropolis, the talents of our young candidate for scientific distinution and improvement found every possible encouragement and advantage. Here, although the practice of surgery seems to have been his first object, probably with more direct views to a maintenance; he soon refined every other pursuit for the first passion of his youth, and botany henceforth engaged all the faculties of his mind. He soon discovered the science to be just then in a state to make the scientific fortune of a man of enterprise and genius. Botany had, for some time, become a leading taste among persons of rank and opulence, by which the materials for its improvement had accumulated, but the advancement of the science itself had not, by any means, kept pace with its riches. Men of the first rank in human intellect, who had fixed everlasting landmarks in other departments of knowledge or literature, though they had done much in botany and other branches of natural history, had but imperfectly accomplished any great systematic plan of technical distribution or discrimination, without which mere practical knowledge is but an indigested chaos. The lucid order, and rapid perceptions, of Tournefort's mind, with whom Vaillant was soon familiarized, as one of the most diligent pupils, could not but strike him with peculiar force, while supplying light of which he so fenibly felt the necessity. But as a lamp, however brilliant, serves to betray the surrounding darkness in an unlimited unexplored cavern; so the achievements of Tournefort, like those of his predecessors and contemporaries, tended as yet to display more of the arduous nature of their undertaking, than of its perfect accomplishment. The common herd of their pupils and admirers, are like the animalcula on a blue-bottle fly; who, as a witty writer observes, "doublet's think their fly the greatest and the bluefet object in the universe," and they can only go where it pleases to lead. But Vaillant, though adoring the genius of Tournefort, and loving his true amiable social qualities, could not but perceive the imperfect execution of much of his plan, and detected at once perhaps many of those faulty principles, which have gradually displayed themselves to subsequent observers.

That he had performed an Herculean task, could not be denied, but that much remained to be done, was but too evident to an acute observer. The great preceptor soon became aware of the talents of his pupil; he held him up as an example to his colleagues, and adopted him as a coadju- tor in the elucidation of the plants about Paris.

After refiding some time at Neully, Vaillant was chosen secretary to Father de Valois, a Jefuit, confessor to the younger branches of the royal family. Here he became known to M. Fagon, first physician to the king (see FAGON); who finding him investigating and arranging mollusks, was much struck with the specific definitions, written in Vaillant's beautiful hand under each, as they fill remain. Fagon soon afterwards took him under his imme- diate protection, promised to further his wishes of travel- singing, and invited him to reside at Paris, till he could procure him an appointment of that kind from the king. This object however was soon given up. Vaillant became secretary to his patron, and was taken into his house. Having free access to every part of the royal gardens, he enriched his own herbarium, and thofe of Fagon and Tournefort, with exotic, as well as native, specimens, which he prepared with skill and dexterity. He likewise added daily to the collection of living plants, and became, under M. Fagon, the director of the Jardin du Roi. At length, in 1708, this faithful and disinterested friend resigned, in favour of Vaillant, his own appointment, of professor and subde- ministrator of plants in that garden, which Tournefort had repeatedly solicited from him in vain. To this great benefit, which Vaillant was anxious, by all possible exertions, to defer, was added the construction of new and ample hot- houses, at the wish of the new professor, and the formation of a splendid cabinet of Materia Medica. His lectures on botany, and especially a "discourse on the structure of flowers," since published, were received with great applause. He was admitted, without solicitation, into the Académie des Sciences; it is even said that he was defirous of declining this honour, which his friends had great difficulty in persuading him to accept. A piece of self-denial, or excessive modesty, the reasons for which are not very apparent.

In the intervals of his other occupations, Vaillant visited, at different times, various parts of France, for the sake of botanical enquiries; but it does not appear that, except his martial expedition into Flanders, he ever extended his travels beyond the limits of his native country. His foreign correpondence, nevertheless, was very extensive, and by this means he greatly augmented the riches of the royal garden.

Notwithstanding Vaillant's original admiration of Tour- nefort, and his personal intimacy with that great and amiable man, of whom we have given an account in its proper place; he very soon, as we have already hinted, became diffatisfied with some of the fundamental principles of his preceptor. He adopted and clearly explained the fexes of plants, and consequently asserted the importance of the ftamens and pistils, in a physiological as well as systematic point of view. This was the subject of his discourse above-mentioned, delivered June 10th, 1717, before his pupils at the Jardin du Roi. On the 17th of December, 1721, he read a professed criticism on the method of Tournefort, before the Academy of Sciences, printed in the Memoirs of that learned society for 1723. We regret to find, in both these performances, much disrespectful mention of his illustrious predecessor; which has been but too severely retailed upon himself, by the neglect which his own just pretentions have received from his countrymen. To have been more in the right than Tournefort, was of itself a sufficient offence; and to have asserted his opinion with alacrity and indecorum, served only to authorize part of the hostility which he incurred. Whatever progress Vaillant had made towards the foundation of a new fytem of classification, he did not live to lay it, in any regular form, before the public. His active life was devoted to the acquisition of materials, which he had no opportunity of employing. His difficulties, doublets, increased with his progres. What parts he did perfect are admirably done; particularly his elaborate exposition of the genera and species of the fynegenous, or compound flowers, published in the Memoirs of the Academy, between the years 1718 and 1722. But the observations and en- quiries of this great botanist had been extended to various other classes and families of plants, though they never ripened into any complete systematic work. The writer of the present article has long ago recorded,
VAILLANT.

v. 1. 243, that the herbarium of Vail1ant, preferred at Paris, displays astonishing instances of his profound knowledge and acute judgment, with respect to the genera, species, and synonyms of plants. The specimens are copious and fine, especially of Tournefort's oriental plants, which are far more perfect and abundant than in that author's own collection. These were obtained by Vail1ant, either from Gaud1efcheiner, the travelling companion of Tournefort, or from others who subsequently purified the same track. We know not that any competition, or open controversy, arose between these distinguished men, during Tournefort's life, who dedicated a genus to his pupil. (See Val1antia.)

Vail1ant is reported to have critically examined the whole of the Institutiones Rei Herbariae, as soon as that great work appeared, in 1700, and to have communicated his remarks to M. Fagon. This intelligent friend declared, that though in the morning he had admired the performance of Tournefort, he could not withhold his approbation of Vail1ant's remarks by the light of mid-day. Tournefort died in 1708, and Vail1ant's first public attack, except what might incidentally fall from him in lecturing, was made, as we have said, in 1721. We are informed thus much of the principles and aims of Vail1ant, that, having established the doctrine of the sexes of plants, he proposed to distinguish his classes by the parts of the flower, and his genera by characters taken indifferently from the whole plant, according as might best suit his purpose. In this latter respect, he was but returning towards the dark knfs of former ages, and we can have nothing to regret. His bold and most meritorious attempt respected nomenclature. He wished to distinguish every genus by an expressive name, by which its essential characters might at once declare themselves. He flattered himself with extending the same principle to every species of plant, so that a word or two might give its name and character together. The learned reader will be aware of the similarity of this scheme to that of Rivinus, and of its failure, even on the very limited theatre of that writer's scientific operations. (See Rivinus.) He will also recollect that it succeded with Linneus, only because the latter had the good fortune, or good sense, after discovering that these two objects, of nomenclature and clear discrimination, were in themselves incompatible, to reconcile both by division.

While these pursuits engaged the mind of Vail1ant, his bodily constitution was yielding to the fatigue he had too long imposed upon it. Exposure to cold and wet, and to the night air, in many of his botanical rambles, did but ill suit a delicate frame, prone to pulmonary diseases. In proportion as he perceived a decay of strength, he only exerted himself the more, to complete the undertakings which had been the object of his life, and which might have demanded something like a patriarchal term of existence. He suffered for about four years under a consumptive attack, in the course of which he expectorated little hard concretions, amounting, says Boerhaave, to above 300, and at length expired, in a tranquil manner, on his birthday, May 26th, 1722, aged fifty-three. He was tall, well-proportioned, and active; of an open generous disposition, hating flattery, and misanthropic even of his own praise. The character of his criticisms upon Tournefort is rather, as we should hope, to be attributed to blunt sincerity, than to any portion of jealousy or envy, of which his conduct, in other infinences, betrays no traces. He had the satisfaction of soothing, by the most affiduous care, the sufferings of his friend Fagon, who underwent an operation for the stone at a very advanced age; and who would gratefully have ceded to Vail1ant, as a recompense, the profits of an impoll which he enjoyed upon mineral waters. This Vail1ant had the still higher gratification and honour of declining.

His rich and splendid herbarium, comprehending that of M. Fagon, which had been given him by the son of his old friend, as well as his own cabinet of various natural curiosities besides, were purchased by the king, Louis XV., and deposited in the museum at the Jardin du Roi, where they have fortunately remained in safety amid the wreck and the restoration of a kingdom. His library was left in the hands of his widow, whose name was Françoise Nicole Bof1net. Vail1ant married this lady on the 14th of October, 1701, and enjoyed with her twenty-one years of great conjugal happiness, but had no offspring.

The greatest object of temporal concern, on his deathbed, was a work on the plants around Paris, which he had long been preparing, and for which Claude Aubriet, the inimitable botanical draughtsman of that day, had made, under the inspection of the author, above 300 drawings. Anxious that his labours should not prove altogether fruitless, Vail1ant wrote, a year before his decease, to the famous Boerhaave, requesting him to take this orphan work under his protection. To this request, backed by their mutual friend William Sherard, Boerhaave readily acceded. Vail1ant declared that he had particular and very strong reasons, which he could not explain, for making this request. He probably feared that his countrymen, veneration of Tournefort, who no longer flood in their way, might not be over anxious to preserve the relics of his rival, whose fame and activity had so lately clothed with their own. Whatever were his feelings on this subject, Vail1ant was satisfied with Boerhaave's acceptance of this trust, and awaited his long expected change with the piety and composure becoming a Christian and a true philosopher.

Boerhaave published the work of his departed friend in 1727, under the title of Botanica Parisiensis, making a very handsome folio volume, with thirty-three admirable plates, comprehending above 300 figures, of rare or obscure species, in which the cryptogamic plants are very abundant. The flowers alone of all the Orchis tribe are exhibited; their herbage being so nearly uniform as to be deemed lefs necessary. These figures, though uncoloured, leave scarcely anything to be desired. The arrangement of the work is alphabetical, and its language, except the specific definitions, French, like all the author's compositions. The elegancies of style, or refinements of language, do not seem to have made a part of his studics, and he was rather a scientic than a learned botanist, except what was neccessary for the accurate appropration of synonyms, in which no one, fo far as we have traced his progress, was superior to Vail1ant. Dillenius, a professed and elaborate botanical critic, was undoubtedly, by many degrees, below him. Certain imperfections of this popular work, justly indicated by Haller, arose, as he observes, from Boerhaave's inability to betow sufficient time on the correction of the unfinished manuscripts. Hence many repetitions occur, and some of the figures want references. Following authors have generally cited the beautiful figures, without advertsing to the text; in which, notwithstanding, much may be found worthy of notice, especially all the practical observations, and original descriptions, of Vail1ant himself. We cannot too strongly commend him as a botanist of originality, acuteness and accuracy, who has contributed to the general stock of botanical knowledge, and whose genius, had he lived longer, might have greatly extended the limits of philosophical speculation, on the subject of arrangement. —Vail1ant's Works, and his life by Boerhaave. Haller Bibl. Bot.

VAILLY, in Geography, a town of France, in the department
VAIR, in Heraldry, a kind of fur, or doubling, consisting of divers little pieces, argent and azure, refembling a Dutch U, or a bell-gla$.

Vair have their point azure opposite to their point argent, and the safe argent to the azure.

When there are only two or three vairs, the ancient herals call it great vair; and when there are more, small vair.

Vair is intended to represent a kind of skin, used anciently by the kings of France, in lieu of a fur, and with which the gowns of the prelates a mortier, the counsellors of the court, the heralds' coats, &c. were lined till the fifteenth century.

It was properly the skin of a kind of squirrel, called also in French vair, and in Latin sericeus; which was white underneath, and of dove-colour at top. It is described by Aldrovandus under the name of ferrico vairo, and is the same, according to Geminier, with the mus Pnicus of Aristotle and Pliny; which the Latins call varus or varius, from the variety of its colour. Its two skins, joined together, make the figure of the vair in armories; being naturally whiter than azure.

Vair, Colombiere observes, is the second sort of fur anciently used as a lining of the garments of great men, consisting of little pieces, sewed by the furriers on white skins: and because these pieces were usually blue, those who first settled the rules of heraldry, decreed, that this fur, in its natural blazon, should always be argent and azure. So, if it be absolutely said, such a family bears vair; it is supposed to be argent and azure.

Regularly there must be but four rows or ranks of vair in the shield; if there be either more or less, the number must be specified. The smallest number, being three rows, is called beffroy de vair; the molt, being five or fix, is called menu, or small vair.

The beffroy is also known by the first figure on the dexter side of the escutcheon being always of metal, and in form of a belt; whereas that of menu vair is in shape of a glas.

VAIRA, in Geography, a river of France, which runs into the Var, about 3 miles N.W. of Glandes.

VAIRE, in Geography, a river of France, which runs into the Var, about 3 miles N.W. of Glandes.

VAIRE, in Geography, a town of France, in the department of the Lot; 4 miles N.E. of Martel.

VAIRAMEA, in Mythology, a name of the Hindo god Siva, under which name Siva is usually given to Indra, called Vairaca, meaning lightning or thunder. Siva under this name will therefore correspond with the Jupiter fulminator or tonans of the West. Siva's confort, Parvati, is furnished Vairamur, pronounced sometimes Bajrephari; the initials being so extensively interchangeable.

VAIRAS, in Geography. See Vairen.

VAIRY, Vaire, Parry, or Parry, is applied to a coat, or the bearings of a coat, when charged, or chequered, with vair.

When the colours are argent and azure, or white and blue, it is vairy proper; if bithe otherwise, the colours are to be expressly named; vairy of such a colour or metal. He bears vairy, or, and vert; this is particularly called vair compo$ed. The bearings are likewise said to be vairy, when they are charged with vairs. When chiefs, crofles, paies, feales, &c. happen to be vairy, the number of ranks are to be specified.

Vairy gowns are described, by Julius Pollux, to have been
the habit of the ancient Gauls, as ermines were of the Armenians.

VAIRY-cups, or VAIRY-tarts, or Potent-counter, Counter-poison, is a bearing in heraldry, composed of pieces representing the tops of crutches, or potences counter-placed.

In blazon, the colours must be expressed; as azure, argent, &c.

VAISETTE, Joseph, in Biography, a native of Guillac, in the diocese of Alby, was born in 1685, and entered among the Benedictines of St. Maur, at Touloufe. In 1713 he settled at Paris, and engaged, in concurrence with Claude de V, Vie, of the same fraternity, in the history of Languedoc, of which the first volume appeared in 1730, in folio: and upon the death of his coadjutor in 1734, it was continued by himself, four more volumes having been published, and a fifth being in preparation at the time of his own death. This history is highly commended, on account of both the learning and moderation displayed by the author. An abridgment of this history, in 6 vols. 12mo., was published by Vaiette in 1740; and he was also the author of an "Universel Geography," in 4 vols. 4to., and 12 vols. 12mo., 1755, which at the time of its publication was generally approved. The author's erudition was extensive, and his disposition was amiable, so that he died, much regretted, in 1756. Moreri.

VAISHNAV, the general name of all the different sects of Hindoos who worship Vishnu, either directly or indirectly, through his comfort Lakshmi, or in one of his incarnations called avatars. In the article Sects of Hindoos, we have concentrated the chief of what we have to offer on the subject of the numerous individuals comprehended under the denomination of Vaishnava; which, in its most extended sense, includes considerably more than half of the whole race of Hindoos. The distinction of Saiva, or Siva-Bakht, comprehends the other portion. See SAIVA.

The second plate of the Hindoo Pantheon contains many sectarial marks, or symbols, by which the different sects distinguish themselves generally speaking, horizontal lines on the forehead mark the Saiva, while perpendicular foreheads indicate some sect of Vaishnava. These lines are red, white, or yellow, with different coloured spots over, under, or between them; all of which are said to have some mythological allusion.

VAISHNAVI, in Hindoo Mythology, is a name of the goddesses Lakshmi, the comfort or energy of Vishnu; as such, she is called his fakti. In the different incarnations of Vishnu, Lakshmi accompanied him, either under her own name, or under some other denomination.

VAISHISHKA, in Philosophy, is the name of one of the six Hindoo schools, or sylums. Under the article Philosophy of the Hindoos, we have enumerated the principal schools of that thinking race. The Vaiishikha is a division of the Nyaya, and we refer to the latter word for some notice of the doctrines of its followers.

VAISON, in Geography, a town of France, in the department of the Vaucluse, on the Oueze: before the French revolution the fee of a bishop, suffragan of Avignon: the old town has been long in ruins; 22 miles N.N.E. of Avignon.

VAJRA VA, in Mythology, a name of the Hindoo Plutus, who is more commonly called Kuvera: which see. Vairava, or Vifra, is a name given also to Ravena, half-brother to Kuvera. (See RAVENA.) Vifraa is sometimes called their father, and they are then named Vairavana.

VAISSEAUX ENFLEZ, a term used by the French writers in Chemistry, for the vessels used in distilling in an open fire, or in fad, which do not consist in the common way of a retort, joined immediately to a receiver, but have a receiver with a double opening, and a neck at each end, placed between the retort and the ordinary receiver. The neck of the retort is let into one of the necks of this middle vessel, and its other neck is thrust into that of the receiver; by this means the receiver, into which the liquor is to fall, stands at a greater distance than it otherwise would from the fire, and the vapours are more easily condensed in it by its coldness, while they have also a double or treble space to expand in, and by that means are not so likely to burst the vessel.

VAIVASWAT, in Mythology, a name of Surya, the Hindoo regent of the sun, as noticed in the article SURYA, where he is under this name styled, on the authority of Sir William Jones, "Lancer of the golden ray." The very important deity Surya is frequently called in Hindoo books by the title of Vaivaswat: and those personages who, like the ancient Incas of Peru, are pretended to be of solar origin, are called Vaivaiswata. In the Gita, Krishna says, "This immutable sfylem of devotion I revealed to Vaivasvat, ('or,' says the commentator, 'the fun'), Vaivasvat declared it to his fon Menu; Menu explained it, &c." This Menu is the author of the celebrated Infitutes that bear his name: he is also named Satyavrata, and is reasonably believed to be the fame with the Noah of Scripture. (See Menu and SATYAVRATA.) These offspring of the fun are likewise called Suryavanshi; and this: and some farther notice of their curious coincidence with the solar race of Peruvians will be found in our articles Rama and Sita. The Hindoo Pluto is sometimes called Vaivaiswata Yama; denoting, we conclude, his solar origin.

VAKEF, in Geography, a town of Arabia, in the province of Nededs; 100 miles N. of Jamama.

VAKIA, in Commerce, a weight in Peria and Arabia. At Bassorah, the weights for merchandise are, the maund attary, the maund fey, and the oka of Bagdat. The maund attary contains 25 vakias tary (sometime reckoned at 24 or 26 vakas), and weighs 28 lbs. avoirdupois, or the vakia 10 ounces. The maund fey, or maund Bassorah, contains 24 vakias fey (called okas of Bassorah), equal to 76 vakia tary, or 90 lbs. 4 oz. avoirdupois. The oka of Bagdat is 23 vakias tary, or 47 lbs. avoirdupois. In fales of ginger, pepper, and coffee, 26 vakas are allowed to the maund; in fales of cardamoms, fugar-candy, and benzoin, 25 vakas per maund; and in fales of sugar and metals, 24 vakas per maund. The vakia tary, which should be about 115 mifals (the mifal weighing about 72 English grains), varies from 110 to 118, and the others in proportion.

At Betelagu, or Betlafackee, in Arabia, a rattle of coffee contains 14½ vakas, and a farcel, or farzil, of the fame, 290 vakias; of dates, candles, and iron, 16 vakias are reckoned to a rattle; of all other sorts of goods, 15 vakas make a rattle. At Mocha, gold and silver are weighed by the vakia of 10 cofalas, or 160 carats: 24 carats = a mifal, and 1½ vakia = a beak: 100 Spanish dollars weigh 87 vakias, so that a vakia weighs little more than 1 oz. English troy weight; the bahar contains 15 farzels, or 150 maunds; the maund = 40 vakias; a rattle is = 15 vakas, but in coffee, 14½ vakias are reckoned for a rattle; 2 rattles for a maund, and 10 maunds, or 290 vakas, for a farzil. Kelly's Univ. Cambiff.

VAKUNAIKA, in Geography, a river of Ruffia, which runs into the Kifenga, N. lat. 56° 16'. E. long. 88° 14'.

VAL, L.A. See LAVELD.

VAL, La, a town of France, in the department of Mont Blanc; 20 miles E. of Montlfer.
VAL

VAL., Le, a town of France, in the department of the Var; 3 miles N. of Brignoles.

VAL di Compare. See Teakt.

VAL de Morea, a town of Spain, in the province of Leon; 12 miles E. of Ponferrada.

VAL de Prades, a town of Portugal, in the province of Tras os Montes; 16 miles E.N.E. of Miranda.

VAL de Ricuer, or Val de Ricuer, a town of France, in the department of the Calvados; 12 miles N.W. of Caen.

VAL Ratsado, a town of Naples, in Lavora; 15 miles S.E. of Sora.

VAL de Salas, a town of Spain, in Galicia; 22 miles S. of Orense.

VAL de Santiago, a town of Portugal, in the province of Alentejo; 27 miles S.W. of Beja.

VAL de Travers, a district of the principality of Neuchatel, about 18 miles in circumference, and containing about 3500 inhabitants; It is situated between Neuchatel and Pontarlier.

VAL di Trompia, a valley of Italy, in the Brevign, containing 19 parishes, and about 13,000 inhabitants, chiefly employed in the manufacture of iron.

VAL de Vareas, a town of Spain, in the kingdom of Seville; 10 miles from Lucena.

VAL de Uxos, a town of Spain, in the province of Valenla; 17 miles S.E. of Segorbe.

VAL. in Ancient Geography, a town of the interior of Thrace. Polemy.—Allo, a town of Africa, in Mauritania Tingitana. Ptol.

VALADARES, in Geography, a town of Portugal, in the province of Entre Duero e Minho; 5 miles S.W. of Melgaco.

VALAGODE, a town of the island of Ceylon; 60 miles S. of Candy.

VALAIS, or VALLAIS, an independent republic in alliance with the thirteen cantons of Switzerland, and which has formed a particular league with the seven Catholic cantons, for the defence of their religion. This tract of country stretches from E. to W. about 100 miles, and contains 100,000 inhabitants, professing the Roman Catholic religion. It is divided into Upper and Lower Vallais; the ormer reaching from the Furca to the Morge, below Sion, which is its capital; and the latter, from that river to St. Gingou, situated upon the lake of Geneva. From the mountain of Furca, its eastern boundary, two vast ranges of alps inclose the Vallais; the southern chain separates it from the Milane, Piedmont, and part of Savoy; the northern from the canton of Bern. These two chains, in their various windings, form several small valleys, watered by numerous torrents that rush into the Rhone, as it traverses the whole district, from the Furca to St. Maurice. A country thus entirely inclosed with high alps, and confining of plains, elevated valleys, and lofty mountains, may be naturally suffused to exhibit a great variety of situations, climates, and productions. Accordingly, the Vallais presents to the curious traveller a quick succession of prospects, as beautiful as diversified. Vineyards, rich paitures covered with cattle, corn, flax, fruit-trees, and forests, occasionally bordered by naked rocks, crowned with everlasting snow.

The productions of the Vallais vary according to the great diversity of climates by which this country is diversified. It supplies more than sufficient wine and corn for interior consumption, and exports a considerable quantity of both; the soil in the midland and lower districts being exceedingly rich and fertile. In the plain, where the heat is collected and confined between the mountains, the harvest is usually finished in July; whereas, in the more elevated parts, barley is the only grain that can be cultivated with any success, and the crop is seldom cut before November. About Sion, the fig, the melon, and all the other fruits of Italy, come to perfection. In consequence of this singular variety of climate, the traveller in the same day may indulge himself with strawberries, cherries, plums, pears, and grapes, each of which is the natural growth of the country.

Both the hills and valleys of the Vallais breed cattle in abundance, and yield plenty of game. The mountains are supposed to contain lead, copper, and silver mines; but the products, it is supposed, would not defray the expense of working them. Here is likewise pit-coal. The Vallais is noted for two hot-baths of celebrated virtue, as those of Brug, or Gleeo, and Leuck, the latter of which is commonly known by the appellation of the Vallais bath. In the upper tythings the prevailing language is the German, but the inhabitants of Sion, in the Upper Vallais, with all in the Lower, speak a corrupt French; though in both parts, especially in the chief burg, they apply themselves to the German, French, Italian, and Latin; being all indifferently necessary to them in their intercourse with the cantons of Bern and Uri, Savoy, Piedmont, and the Milane; therefore a stranger cannot but be surprised at the fluency with which the meanest people here speak those four tongues.

The ancient inhabitants of this country were the Lepanti, Vibra, with the Sedani and Varergi, who hold their liberty dear to Sergius Galba, general of Julius Caesar. In the middle ages it came to be called Valefia, and in 1032, under the emperor Conrad II., devoted to the German empire, as a part of the second Burgundian kingdom. In the year 1035, that prince made over the Lower Vallais to the counts of Savoy. The inhabitants of the Upper Vallais resolutely maintained their liberties, as well against the dukes of Zaringen, who, in the year 1157, were by Frederic I. appointed guardians of the bishopric of Sion; as against the bishops of that see, who assumed the title of counts of the Vallais, and after that drove out the families of the barons Tour and Karen, who had usurped a dangerous authority among them. In 1475, the bishop of Geneva fell on the Upper Vallais with a body of 18,000 men, consisting of Lower Vallaisians and Savoyards; but the Upper Vallaisians, being afflicted with 3000 troops by Bern, Friburg, and Solothurn, their allies, defeated the bishop, and even made a conquest of the Lower Vallais, which ever since that time has been subject to them. In the same year, also, they formed a perpetual alliance with Bern, which was renewed in 1643; and in 1529, with the whole Helvetic body. In 1553 they entered into a more particular union with the seven popish cantons.

At an early period of the French revolution, the disaffected party of the Lower Vallais appealed to France to emancipate their country from their subjection to the Upper Vallais, but the French not having matured their scheme of fraternization, their petition was rejected.

In February 1798, however, the people of the Lower Vallais were enfranchised, and admitted to an equality of rights by the Upper Vallais; but after the conquest of Bern, and the revolution of the greater part of Switzerland, the inhabitants of the Upper Vallais rejected the new constitution, took up arms, and defended themselves with great spirit. After several bloody defeats, and the capture of the cattle of Sion, which was formed by the French, the natives submitted, and both districts were moulded into one department, called the Vallais.

There are no manufactures of any consequence; and indeed the general ignorance of the people is no less remark-
able than their indolence; so that they may be considered, in regard to knowledge and improvements, as some centuries behind the Swis, who are an enlightened nation. The peasants seldom endeavour to meliorate those lands where the soil is originally bad, or to draw the most advantage from those which are uncommonly fertile: having few wants, and being satisfied with the spontaneous gifts of nature, they enjoy her blessings without much considering in what manner to improve them.

The Upper Vallais is sovereign of the Lower Vallais, and comprises four independent districts, or commonwealths; namely Sion, Goms, Breiz, Vifp, Leuc, and Siders; of these, Sion is aristocratical, and the others democratical. They are called dixains, because the Upper Vallais being divided into seven, and the Lower into three districts, each division is a dixain, or tenth of the whole.

The bishop of Sion was formerly absolute sovereign over the greater part of the Vallais; but his authority is at present limited to a few particulars. He has the sole power of pardoning criminals, and figus the warrants for execution; the money is coined in his name, and with the arms of the republic. In his acts he beys himself bishop of Sion, prince of the German empire, and count and prefect of the Vallais; in days of high ceremony he dines in public, and is waited upon by the first noble of the Vallais, who is hereditary treasurer. He nominates also the bailiffs or governors of the two bailiages of Martigny and Arden, and possesses considerable influence from his patronage of church preferment. Upon a vacancy in the see, the canons of the chapter of Sion present from their own body four candidates, one of whom is appointed bishop by the landstrach, or general diet.

The seven dixains form, conjointly with the bishop, the republic of the Vallais, and all affairs are transacted in the diet, called landstrach, which meets twice every year at Sion. This assembly consists of nine voices; the bishop; the lands-hauptmann, who is chosen or confirmed by the diet every two years; and the seven communities. The bishop presides; the lands-hauptmann collects the votes; and all resolutions are decided by the majority. Each dixain, although it has but one vote, sends as many deputies as it pleases; the seven generally consist of four; a judge, a bannere, a captain, and a lieutenant. The judge and the lieutenant are appointed every two years: the two others hold their offices for life.

In all civil causes of a certain importance, an appeal lies from the inferior courts of justice to the diet in the last resort. Thus, by the institution of this supreme council, the communities in this country are firmly united, and form in conjunction one body politic, or republic, for the general affairs of the nation. In other cases, each of the commonwealths is governed by its own particular laws and customs.

Both the Upper and Lower Vallais were formerly dependent upon the bishop of Sion; but the inhabitants of the two districts united in order to limit his power; and, having succeeded, quarrelled for superiority. A bloody war ensued; which terminated in 1475, by the total defeat of the Lower Vallaisians. Since that period, they have continued subject to the Upper Vallais, with the enjoyment, however, of some considerable privileges.

The inhabitants are generally of low stature, and those of that part of the Vallais in which the capital (see STOX) is situated, are very subject to goiters, or large excrescences in the neck, which frequently increase to an enormous size, and what is more extraordinary, idiocy is no less prevalent. The weather in this inclosed vale is exceedingly fultry and oppressive. This languid heat is probably one of the causes which occasion the inconceivable indolence of the inhabitants: much, however, must at the same time be attributed to the richness of the soil, which precludes the necessity of labour by almost spontaneously producing the fruits of the earth. In fact, the people allift nature very little: they suffer the vines in the vineyards to trail upon the ground; whereas, if the branches were properly supported, the owner would be well rewarded by the superior quantity and quality of the produce.

The uncleanness of the common people is disgusting beyond expression. Although the Lower Vallais exhibits as much uncleanness, its natives are not altogether so indolent as those of Sion and its environs. This imputation of indolence will not hold good with respect to all the inhabitants of the Upper Vallais: for in the eastern part of that district, the soil, though far inferior, was much better cultivated, and the people seemed industrious. Some physical reasons may be assigned for this difference; for there the weather is not so fultry, the water is not unwholesome, the air remarkably salutary, and none of those goitrous persons or idiots were observed common in the midland parts. See MARTIGNY and St. MAURICE.

VALANTIA, in Botany, was originally so named by Tournefort, in honour of his pupil SEBASTIAN VAUJANT, see that article. The latter, as Linnæus remarks, was disfatisified with this application, and wished, on that account, to set aside all names of botanists, as applied to genera, because he perceived the VALANTIA of Tournefort not to be distinct from CRUCIATA of the same author. He was so far correct; but there have been several species referred since to Valantia, which appear to constitute a good genus, whose limits the writer of this has attempted to define, in the Flora Graeca and its Prodrömus, and which will here be exemplified.—"Tour. in Mem. de l'Acad. des Sc. for 1706. t. 5." Sm. Fl. Greæc. Sibith. v. 2. 28. Prodr. v. 1. 95. Linn. Gen. 543. Schreb. 723. Willd. Sp. Pl. v. 4. 947. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 434. Dill. Gen. 147. t. 8. Mich. Gen. t. 7. Jull. 197. Lamarck Hûtâr. t. 843. (Gallium hifipidum; Gertn. t. 24.)—Clas and order, Tetrándria Monogygna. (Polygama Monocœa; Linn.) Native Order, Stellæs, Linia, Rubiæceæ, Jull. Gen. Ch. t. 4. Perianthii. Cor. 4; Petals three-flowered, variously shaped, enlarged after flowering, containing the solitary fruit. Car. superior, of one petal, flat; that of the central flower with four, of the lateral, or male, ones with three, deep ovate segments. Stam. Filaments in the central flower four, in the lateral ones three, thread-shaped, curved, alternate with the segments, and half as long; anthers roundish, of two cells. Pijf. German solitary, inferior, concealed in the receptacle, belonging to the central flower, with the rudiments of two seeds; style in the central flower only, deeply divided, fearfully long as the stamens; stigma obtuse. Peric. formed of the enlarged permanent receptacle, gibbous, inflated, of one cell. Seed generally solitary, sometimes two, ovate, concealed in the receptacle, smooth.

Obf. The above limitation of the genus before us excludes V. pedemontana, Willd. n. 4; bimafisa, Willd. n. 6; taurica and cheiopinacifera, Willd. n. 9; and 12, with V. Apa- rine, articulata, Cruciata and glabra, of Linnæus, all which eight species belong, if we mistake not, to Galium. Willdenow has already properly removed from this genus V. hypocarpa, which is, as Browne and Pursh make it, a species of Rubia, very remarkable, however, for its apparently superior

12
Valentine. But we apprehend that what looks like an inferior calyx, may be four bracteas, and that this species, like Rubia tinctorum, may have no real perianth.

1. V. muralis. Wall Crows-wort. Linn. Sp. Pl. 1490. Willd. n. 1. Ait. n. 1. Sm. Fl. Grec. Sibth. v. 2. 28. t. 137. (V. annua quadrifolia verticillata, floribus ex viridi palmo cervicio, frutto echinato; Mich. Gen. 13. t. 7. Cruciat, nova roman. minima muralis; Colum. Echpr. 929. f. 2. Rubia quadrifolia, verticillato femine; Bauh. Hift. v. 3. 718.)—Fruit lobed; its angles fringed with teeth. Whorls crowded. Native of walls and dry banks in Italy and the south of France, as well as in Greece. Dr. Sibthorpe gathered it on mount Hymentus, near Athens, and on the hills of the country of Argos. The root is small and annual. Stems several, about a finger's length, ascending, clothed with numerous whorls of small, obovate, entire leaves, four in a whorl, a little hairy on each side. Flowers axillary, one to each leaf, small, sessile, pale yellow. Fruit of a singular appearance, much larger than the flowers, deflexed; gibbous and smooth at the base, lodging a solitary ovate, smooth seed; its lobes divaricated and toothed.

2. V. bipalda. Brilli Crows-wort. Linn. Sp. Pl. 1492. Willd. n. 2. Ait. n. 27. Sm. Fl. Grec. Sibth. v. 2. 29. t. 138.—Flower bilateral. Whorls rather remote. Native of the south of Europe. Dr. Sibthorpe gathered it on the mountains of Crete, and has supplied the only figure that exists of this species. An annual herb, twice the size of the foregoing, and distinguished by its longer, narrower, more diftant leaves; but more essentially by the oblong form of its common receptacle, or fruit, beset with pale rigid bristles, and not fringed, in whose gibbous smooth base is lodged a solitary seed, whose infertion is erroneously represented by Gaertner. Miller cultivated both these species, but nothing can be less likely to interest a mere flower-garden botanist. To those who study natural genera, and their affinities, these plants are highly curious, and sufficiently demonstrate Valaria to be distinct from Galium.

3. V. filiformis. Leaf Crows-wort. Ait. n. 3. Willd. n. 3.—Flower cylindrical, scaly, without prickles, longer than its stalk. Leaves lanceolate, somewhat fringed. Gathered by Mr. Maffon, in Teneriff. Root annual. Stems simple, a span long, bipalda. Leaves four in each whorl, somewhat flaked, reticulated with veins; the lower ones roundish. Common receptacle beset with minute, lanceolate, chaffy scales.

4. V. Cucullaria. Hooded Crows-wort. Linn. Sp. Pl. 1491. Amoen. Acad. v. 4. 296. Willd. n. 5. Ait. n. 5. (Cucullaria; Buxb. Cent. 13. t. 19. f. 2.)—Bracteas ovate, flaked, deflexed, concealing the Oblong furrowed hairy fruit.—Gathered by Buxbaum, in Capadocia, and by Haeflirguett in Arabia, on hills, flowering in May. A small, branching, annual herb, with square rough-edged stems. Leaves ovate, flaked, revolute, rough with minute prickles. Flowers very small, yellowish, on branched axillary spikes, each spike bearing three flowers, and as many large, pale, reticulated, smooth, overshadowing bracteas, which well mark this species, and caused Buxbaum to distinguish it as a genus, by the name of Cucullaria. The plant is, however, a true Valaria.

5. VALARSA-KERD, in Geography, a town of Turkish Armenia; 15 miles W. of Diadin.

6. VALAY, a small island near the west coast of North Uist. N. lat. 57° 37'. W. long. 7° 29'.

7. VALBASE, a town of Spain, in Old Cafell; 15 miles W.S.W. of Burgos.

8. VALCA, a river of the Popedon, which runs into the Tiber, about 5 miles above Rome.

9. VALCALDE, or VILLALCALDE, a town of the Genoese republic; 10 miles N. of Genoa.

10. VALCENBURG, a town of Holland; 3 miles N.W. of Leyden.

11. VALCKENSTEIN, a town of the duchy of Wurzburg; 5 miles N. of Gerolzhoften.

12. VALCOUR. See WALCOUR.

13. VALDAGNO, a town of Italy, in the Vicentin; 17 miles W. of Vicenza.

14. VALDAJA, or VALDARY, a town of Russia, in the government of Novgorod; 72 miles S.E. of Novgorod. N. lat. 57° 50'. E. long. 33° 44'.

15. VALDARACETE, a town of Spain, in New Cafile; 22 miles S.E. of Madrid.

16. VALDASNES, a town of Portugal, in the province of Tras os Montes; 9 miles E.S.E. of Mirandela.

17. VALDAY MOUNTAINS, mountains of Russia, in the government of Novgorod, which are crofted in travelling from Peterburgh to Moscow, and are probably a continuation of the Lapland mountains. They were known to the ancient geographers by the name of Mons Albanus. At present they are indifferently called Vihokaya Plattshade, high rising ground, or the mountains of Valday, from the town and the lake Valday, which are situated on their summits. The country about Valday, being the highest point of the mountain, is extremely pleasant. Fine, flow-rising hills, a charming pellucid lake, with an island on which stands a noble monastery, delightful groves, and an extensive scenery, form the most pleasing variety. These mountains afford numerous and large blocks of granite, quartz, and sandstone, together with felspar, hornblende, mica, fesol, porphyry, jasper and fletiates. The granite blocks are covered with sand and clay. The Valday eminence, which is the highest ridge of these mountains, shapes its course from the north, and appears to take its departure from between the lakes Ladoga and Onega. It then stretches across the Mts, runs between the Ilmen lake, and the Seliger, and extends its foot as far as into the governments of Smolenik, Orel, and Novgorod-Severiki. About its western, southern, and eastern declivities, are several strong flatts of chalk and marle, which in farther progresses are lost in marly and sandy plains. Some naturalists are of opinion, that the whole of this Valday chain of mountains is the effect of violent inundations, and that it entirely consists of a chalk-stone riven from crumbled and destroyed marine productions. But it is not less probable, that the middle part is a primitive mountain, having granite for its principal stratum, which, through a long interval of time, and perhaps under water, is so much decayed as to be in a manner smoothed. No chalk-pit has yet been opened on its summit. Upon the whole it is suppos'd, that all these elevations may be an original mountain decayed and destroyed on its surface, on which, round about its declivities, the loose chalk and marle are floated and deposited. Among these mountains no mine has yet been explored. Some specimens have been obtained of copper and lead; but here is plenty of iron and lime. The extreme elevation of the Valday mountains is very moderate, as the highest point is scarcely 200 fathoms above the level of St. Peterb. Besides the Valday lakes, there are others of inferior note; and at the western foot is the great lake Ilmen, at the southern, the Seliger, &c. Of the rivers, some spring from the mountains, and others are supplied by the lakes that lie at their feet; such are the Vologa, the Duna, the Volkhit, the Lovat, the Pola, the Thagedo, the Klop, the Dnieper, the Don, the Oka, &c. These mountains are sparingly
V A L

sparing clothes with forests, but so much the more with beautiful meadows and fields, so that the graziers derive from them considerable profit. The species of wood are the several sorts of pines and firs, the birch, the linden, the alpen, the alder, &c. The soil in the valleys mostly consists of clay and marl, and is generally fertile. Tooke's View of the Russian Empire, vol. i.

VALDEBUCON, a town of Spain, in the province of Leon; 34 miles N.N.E. of Leon.

VALDECONA, a town of Spain, in Catalonia, on the borders of Valencia; 15 miles S. of Tortosa.

VALDEMANZANAS, a town of Spain, in the province of Leon; 8 miles S.W. of Aitorga.

VALDEMORO, a town of Spain, in New Castile; 13 miles S. of Madrid.—Alfo, a town of Spain, in New Castile; 18 miles E.N.E. of Cuencía.

VALDENSES, in Ecclesiastical History. See VAUDOS.

VALDEPENAS, VALENSAS, in Geography, a town of Spain, in the province of Jaen; 8 miles S.W. of Jaen.—Alfo, a town of Spain, in New Castile; 22 miles S.E. of Cidad Real.

VALDESIA, a town of Spain, in the province of Leon; 23 miles S. of Leon.

VALDIES, a town of France, in the department of the Tarn; 6 miles N.N.E. of Alby.

VALDEZ, John, in Biography, a Spanish reformer and lawyer, was knighted by Charles V. During a tour in Germany he imbibed the principles of Luther; and afterwards settling in Italy, and chiefly at Naples, he became secretary to the king. During his abode in this city, he communicated his sentiments to several persons, and particularly to Peter Martyr and Ochinsus. But though in those religious sentiments he concurred with the reformers, and in his notions regarding the Trinity with those that were denominated Unitarians, he does not appear to have formed any separation from the church of Rome. His discipless, however, were numerous, and attracted the notice of the Inquisition; the dread of which induced several of them to quit the country, and others to retract their opinions. Valdes died at Naples about the year 1540, with an embellished character for piety and virtue, and leaving several works, particularly "Commentaries on various Parts of the New Testament, &c." some of which have been inserted in the Index of the Inquisition, and others censured by the reformers. Beza condemns his treatise entitled "Considerations," charging it with being the source of the errors of Ochinsus. Bayle.

VALDÍÁ. See OVIED.

VALDIGEM, in Geography, a town of Portugal, in the province of Beira, near the Duero; 3 miles N.E. of Lamego.

VALDIVIA, a river of Chili, which runs into the South Pacific ocean, near Valdivia.

VALDIVIA. See BALDÍA.

VALDOR, a town of Hindoostan, in the Carnatic; 8 miles W.N.W. of Pondicherry.

VALDORF, or WALDRON, a town of Wellington, in the county of Renfrew; 3 miles S.W. of Biekefeld.

VALDROME, a town of France, in the department of the Drôme; 18 miles S.E. of Diec.

VALDUS, or WALDUS, Peter, in Biography, was the son of a rich merchant of Lyons, who lived in the twelfth century, and derived his name from Vaux in Dauphine, the place of his nativity. With a mind deeply impressed by the sudden death of a friend, he directed his views entirely to another world, distributed his wealth in alms, and employed himself in propagating just sentiments, as he conceived them to be, of true religion. From another account of this reformer we learn, that about the year 1160, he employed a priest in translating the four gospels from Latin into French, and by the perusal of them adopted opinions very different from those of the Romish church. In 1180, connecting himself with a small society of sentiments similar to his own, he assumed the character of a public preacher. Attempts were made to induce him, but they proved ineffectual; and the number of his followers gradually increased. Expelled from Lyons, he retired to the mountains of Dauphine and Savoy, and propagated his opinions, which were eagerly adopted by the multitude through the adjacent valleys, where they took deep root, so that no persecution or violence could eradicate them. From him, as some say, sprung the sect of the Waldenses. For other particulars, we refer to the article VALDENSES.

VAL of a Pump, at Sea, a term for the trough by which the water runs from the pump along the ship's fides, to the scupper-holes.

VAL of Valley Lands, in Agriculture, are terms applied to any of those which lie in low, narrow, hollow tracts or depressions between hills or rising grounds on their different fides: They are, for the most part, applicable in a more particular manner to gars and dairy practises than others, but sometimes, when suitably dry, to the sphe of the arable kind. They are in many cases very quick in vegetation, and extremely productive; being readily capable of improvements by warping, watering, and other such means; but little expense, which should always be well attended to, in all such lands where there is the possibility of effecting them.

The latter is likewise a term sometimes applied to a gutter or channel in a road or other such situation.

VALENIA, in Geography, a sea-port town of Africa, in the kingdom of Fez, situated on the coast of the Atlantic, in a fertile plain: it is a very spacious natural haven, surrounded by rocks, capable of containing above 1000 ships; but the entrance, which is entirely open to the west, is extremely difficult and dangerous. The coast is lined with rocks near 30 feet in height, which anciently must have been washed by the sea, the Moors living in the caverns hollowed out by the water. At the bottom of the rocks, the sands heaped up by time have formed a plain, laid out into gardens and cultivated: the town is little more than a circle of walls, containing but few inhabitants; 27 miles S.S.W. of Mazagan.

VALEGAR, a town of Hindoostan, in Coimbetore; 15 miles W. of Damiocotta.

VALEGGIO, or VALEZZO, a town of Italy, in the department of the Benaco, on the river Mincio; 14 miles S.W. of Verona.

VALEGIO, a town of Italy, in the department of the Gorgia; 4 miles N.E. of Lumelio.

VALENCIA, a town of Portugal, in the province of Entre Duero e Minho, on the S. side of the Minho, opposite Tuy in Spain, and said to have been founded by the soldiers of Viriatus. It contains two parish-churches, an hospital, two convents, and about 500 inhabitants; 16 miles W. of Oporto. N. lat. 43°. W. long. 5° 20'.

VALENCIA, a town of Spain, in Estremadura, on the borders of Portugal; 24 miles S.W. of Alcântara.

VALENCIA de Alcantara, a town of Spain, in Estremadura, on the borders of Portugal; 24 miles S.W. of Alcântara.
of Beira, situated about half a league from the Duero; 12 miles W. of St. Joao de Pesqueira.

VALENCE, a town of France, and principal place of a district, in the department of the Lot and Garonne; 12 miles S.W. of Agen. N. lat. 44° 6'. E. long. 0° 59'.—Also, a city of France, and capital of the department of the Drôme, on the left side of the Rhône; anciently a Roman colony, called Julia Augusta. Before the revolution it was the see of a bishop, and capital of a principality called Valentinois. An university was brought hither from Grenoble in the year 1454; 16½ posts N. of Avignon. N. lat. 44° 55'. E. long. 4° 59'.

VALENCIA in Albigeois, a town in France, in the department of the Tarn; 12 miles N.E. of Alby.

VALENCE, a province of Spain, bounded on the N. by Aragon and Catalonia, on the E. and S.E. by the Mediterranean, on the S.W. by Murcia, and on the W. by New Cañile, about 220 miles in length from N. to S. ; the breadth is unequal, from 20 to 45. Valencia is, in proportion to its extent, one of the best peopled provinces of Spain, and contains seven cities: has four sea-ports, the most considerable of which is that of Alicante; the soil is extremely fertile, although divided by mountains. These contain mines of sinopica, or blood-stone, iron, and alum. There are also found quarries of marble, jasper, plaster, lapis calaminaris, and potter's-clay, of which different kinds of earthen vessels are made. The climate is mild and pleasant, but there is something enervating and faintish in the air; vegetables with the finest outward show imaginable are not good to the taste. No women work in the fields; but this may proceed from their constant employment within doors, as much as from any remains of Moorish jealousy, though the Valencians still retain much of the features and manners of their old Saracen masters. To this day the farmers will not allow their wives to sit at table, but make them stand at their elbow and wait upon them. The inhabitants of this province are said to have more of the fifth and fuller unpolished manners of the old Spaniards, and to have adopted the best of foreign improvements in civilization, than most other parts of Spain. This kingdom and city were conquered by the Moors under Abdallah Cis, and recovered in 1094, when the famous Cid Ruy Diaz de Vivar, taking advantage of the confusion and civil war that raged in Valencia, after the murder of Sultan Hiaya, made himself master of the city by storm, at the head of a chosent band of valiant knights. This was the last exploit of that hero, so long the terror of the Mussulmen. A few days after his death, the king of Cañile, finding it too far distant from his other dominions to be conveniently succoured in case of a sudden attack, thought proper to withdraw his troops, and suffer the Moors to repel one of their attacks. It was again taken from them by James I., king of Aragon, in the year 1238, and for ever united to that crown, the fate of which it has ever since followed through all its various revolutions. In the beginning of the reign of Charles V. this province was distracted by civil commotions and struggles between the nobility and commons. The population of the whole kingdom of Valencia amounts to 17,921,211 vecinos, or 716,884 souls, resident in 570 towns and villages. The manufactures of silk are the cause of a population that may be reckoned considerable, if compared with that of other provinces of Spain. The produce of this article, on an average of one year with another, amounts to about 500,000 pounds, worth a doublon per pound, in the country. Government has prohibited the exportation of Valencia raw silk, in order to lay in a stock to keep the artificers constantly employed in bad years; for it has sometimes happened, that half the workmen have been idle for want of materials. The great nurseries of mulberry plants in the plains of Valencia are produced from seed, obtained by running a rope of Esparto over heaps of ripe mulberries, and then burying the rope two inches under ground. As the long plants come up, they are drawn and transplanted. The trees, which are all of the white kind, are afterwards set out in rows in the fields, and pruned every second year; in Murcia only every third year; and in Granada never. The Granada silk is esteemed the best of all, and the trees are all of the black fort of mulberry. The fruit exported from Valencia to the N. of Europe may be estimated, communibus annis, at two millions of pezos, about 334,000l. sterling. The annual crop of hemp may be worth 300,000 pezos, at three pezos per arroba: 140,000 loads of rice, at 10 pezos a load, make 1,400,000 pezos. The vintage of 1767 produced 4,309,000 measures of wine, which, at three reals a measure, come to 861,133 pezos. There is also much cotton made in this province from the cotton-plant, which rises to the height of three feet at most, and very much resembles the raspberry-bush. They make in good years 450,000 arrobas, worth 1,550,000 pezos, and in middling years 280,000 arrobas. Notwithstanding all this abundance, nothing can be more wretched than the Valencian peasantry, who can with difficulty procure food to keep their families from starving. Valencia is watered by 35 rivers, all of which run towards the E. It was formerly inhabited by the Celtiberians, the Turdetani, the Lusoni, &c. &c. Valencia was erected into a kingdom, in the year 788, by Abdalla, governor of Valencia, who revolted from the king of Cordova, but was however obliged to pay an annual tribute of 17,000 maravedis. This kingdom continued till the 13th century, when the last king, Zalen, was dispossessed of his capital, and compelled to leave his dominions with 50,000 Moors.

VALENCE, a city of Spain, and capital of the province so called. Its ancient name is unknown; but it is said to have been taken and fortified by Scipio, destroyed by Pompey, and rebuilt by Caesar. It was taken from the Romans by the Goths, and from the latter by the Moors, who twice possessed it 230 years; for it was taken in 994, by the famous Cid Ruy Diaz de Vivar, and bore, during four years, the name of Valencia del Cid. The Moors retook it, but it was finally conquered in 1238, by the king Don Jaime, and embellished as well as enlarged by Don Pedro IV. king of Aragon. It is about half a league in circumference, and the walls are built for ornament rather than defence. Marianna the historian says, that in Valencia cheerfulness enters at the doors and windows: the description he gives of this city is in many respects devoid of truth, and such that the author proves himself more a poet than an historian. Several geographers who have had implicit faith in Marianna, have even exaggerated his account of Valencia, and said the houses here are all palaces, on which account the name of Bella was given to the city, an epithet difficult to reconcile with narrow, crooked, and unpaved streets, impassable after rain; and in which there are but two or three houses built with tafe, and a few churches distinguished by their architecture. It is the see of an archbishop, and an university, instituted in the year 1470. Here is a tribunal of inquisition, with a royal audience, in which the governor, the captain-general of the province, and a royal regent, preside. The number of inhabitants is estimated at 100,000, but perhaps 80,000, or between both, is nearer the truth; 170 miles E.S.E. of Madrid. N. lat. 39° 27'. W. long. 0° 29'.

Accounts are kept at Valencia in libras of 20 soldi, or 240 dimes; also in reals of new plate of 24 dimes. The libra of Valencia is equal to the pez of plate,
er dollar of exchange; it is, therefore, worth 8 reals of old plate, 10 reals of new plate, or 15 reals 2 maravedis yellow. The real of Plata Valenciana, 13½ of which make a libra, is worth 14 sueldos, or 18 dineros, that is, $4 per lb of a real of new plate. The libra is worth $304 per lb. nearer; or, more accurately, 1 lb. is 6 libras, 1 sueldo, 5 dineros of Valencia. A carga or carica weighs 3 quintals, or 12 arrobas; the arroba, 24 lbs. peso grueso, or 36 lbs. peso fútiele: the former pound is 18 oz. the latter 12 oz.; and the ounce is 1⁄2 heavier than the Califian ounce: hence 50 lbs. peso grueso, or 75 lbs. peso fútiele, answer nearly to 59 lbs. avoirdupois. The fútiele, or lighter weight, is used for bread, sugar, tobacco, and spices; the grueso, or heavier weight, for most kinds of merchandise.

Corn is measured by the calizh of 12 barfellas, or 48 decemines: 100 cahisis produce 58½ English quarters. The cantaro, or arroba, liquid measure, contains 4 arrobas; and 25 such arrobas = 88 English wine gallons nearly. The carga of wine consists of 15 arrobas; the carga of oil of 12 arrobas. The vara or ell is divided into 4 palmas, and is about one-half longer than the Califian vara, measuring, therefore, 36½ English inches. Kelly's Un. Camp.

VALENCIA, a town of South America, in the government of the Caraccas; 16 miles S.W. of Caraccas. This city was founded in 1555, under the government of Villacinda, with a view of establishing a port near to Caraccas, in order to facilitate the conquest of the country, which had been much extolled by Faxardo. But Alonso Dias Moreno preferred a situation farther distant from the lake Tacarigua, now Valencia, or half a league W. of it on a beautiful plain, where the air was pure and the soil fertile. N. lat. 10° 9'. W. long. from Paris 70° 45'. Its population in 1801 consisted of 63,487 persons, according to some reports, but according to others, said to be more accurate, of 8,000 souls. The inhabitants are generally Creoles, and the issue of very ancient families, excepting some from the Canaries, and very few Biscayans. The streets are wide, and for the most part paved. The houses are built like those of Caraccas, but not with stone. There is one church tolerably well built, and in the eastern part of a beautiful square, from which it receives, and to which it gives an embellishment, that constitutes the principal decoration of the city. In 1804, another church was erected, and dedicated to our Lady of Chandalie. The Franciscans have a monastery, occupied by eight monks, which has a very neat and elegant church. The inhabitants had formerly the character of being the most indolent in the whole province; but in consequence of some vigorous measures that have been lately adopted, a spirit of greater activity and industry has been excited among them. The situation of Valencia is peculiarly favourable for trade: being separated by only ten leagues of good road from Porto Cavello, it may transport its commodities thither at a small expense; and besides, every commodity from the interior of the country shipped at Porto Cavello goes through Valencia, and that which is defined for Guayaquil passes through Caraccas. The adjacent country produces every sort of provision and fruit in the greatest abundance, and of a most exquisite flavour; and its plains furnish its markets, at a very low price, with every kind of animal which they can consume. Depon's Travels in South America, vol. ii.

VALLENCIENNES, a city of France, and principal place of a district, in the department of the North, situated on the Scheldt, which runs through the town in several places, and here becomes navigable. It is suppos'd to have derived its name from the emperor Valentinian 1, who, taken with the temperature of the climate, and charming situation of the place, laid the foundation of a town, about the year 367, endowing it with many privileges and immunities, and particularly of being an asylum for debtors and criminals. This privilege, which extended over the greater part of the town, was called "banlieue;" but it has since been limited, to prevent abuse from fraudulent bankrupts and_affidians. Before the revolution, it belonged to Hainaut, and contained several churches and convents. The town-house is an ancient building of free-stone, founded in the 14th century; the square or grand place is handsome, but the streets are in general narrow, dark, and crooked. The form of its municipal government was considered so good as to serve for the model of several republics, particularly Venice and Nuremberg, which sent deputies to collect the laws. Near the town is a coal-mine. Valenciennes was one of the first towns which revolted against Philip II. king of Spain; it took part with the States and the Protestant religion, and refused to receive a garrison sent by Margaret of Parma; in consequence of which it was besieged, in the year 1567, by John de Noircarne, Baron of Selles, and at the end of three months surrendered at discretion: thirty-six of the principal ringleaders were punished, and the town deprived of its privileges. It was afterwards several times taken and retaken by the duke of Alva and the States General. In the year 1656, it was besieged by the French, under the command of marquis Turenne and La Ferte; but they were compelled to raise the siege, after the loss of 4000 men killed and wounded, in several assaults. In the year 1677, it was besieged by Louis XIV. in person; and after 17 days, taken by assault. It remained to France by the peace of Nimeguen, which happened in the following year, when a new and landmine Citadel was built at the expense of the citizens, and other fortifications added. In 1793, Valenciennes was invested by the Allies, under the conduct of the Duke of York, and the governor Ferrand summoned to surrender. On the 14th of June, the trenches were opened. The British commander then summoned the garrison;
garrison; but receiving an unsatisfactory answer, the artillery began to play upon the town with great vigour, and in the course of the night above 500 red-hot balls were poured upon it. Towards the beginning of July, the besiegers were able to bring 200 pieces of heavy artillery to play without intermission on the town, and the greater part of it was reduced to ashes. The most singular fact in the history of this siege is, that a considerable part of the war was carried on under ground, mines and counter-mines innumerable having been formed both by the besiegers and besieged. The principal of these, on the side of the former, were one under the glacis, and one under the horn-work of the fortresses; these mines were completed and charged on the 25th of July, and in the night between nine and ten o'clock were sprung with the most complete success. The English and Aufrarians immediately embraced the opportunity to throw themselves into the covered way, of which they made themselves masters. The die was now cast, and on the 26th the duke of York again summoned the place, which surrendered on capitulation the preceding day; the duke of York taking possession of it in behalf of the emperor of Germany. The following year, however, in consequence of the successes of the French arms, Valenciennes surrendered to the republicans, by capitulation, on the 26th of August. The garrison were made prisoners of war, but to be conducted to the frill pot of the imperial and Dutch armies, on condition that they were not to offer against the republic till regularly exchanged. Considerable stores of every kind, with 200 pieces of cannon, 1,000,000 pounds of gunpowder, and 3,000,000 florins in specie, and 6,500,000 livres, were found in Valenciennes; 1000 head of horned cattle, and great quantities of oats and other corn, were also included within the fortresses. So earnest indeed had the emperor been to retain this important place, that he is said to have expended 3,000,000/. in repairing and improving the fortifications. What is the most to be lamented is, that upwards of 1000 unhappy emigrants were surrendered on this occasion to the vengeance of their enraged countrymen. The principal manufactures are lace, cambric, and woolen mitts, camlets, &c. 4 1/2 pofts E. of Douay. N. lat. 50° 21'. E. long. 3° 36'.

VALENGIN, or Vallenin, or Velangin, a town and capital of a lordship, in the county of Neufchâteil. See Neufchâteil.

VALENS, Flavius, in Biography, a Roman emperor, was born at Cibalis in Pannonia, and associated in the empire with his brother Valentinian A.D. 354, at the age of thirty-six. To him his brother, to whom he was much attached, assigned the easternt portion of the Roman dominions, comprehending the whole of Aisa, with Egypt and Thrace; upon this division, Valens made Constaninople the seat of his empire. Alarmcd by the movements of the Persians on the borders of his territory, he departed for Syria, and at Cesarea, in Cappadocia, he was informed that Procopius had taken possession of his capital. The emperor was so terrified by this intelligence, that he intended to negotiate with the usurper, and to propice to him an abdication of the empire. His ministers, however, advised him to detach a body of troops, in order to suppress the insurrection at its commencement; but these troops joined Procopius, and contributed to his success. At length many of the insurgents abandoned their commander, who rendered himself unpopular by his rapacity and tyranny, and he was ultimately betrayed to Valens, who ordered him to be beheaded. The emperor was thus established on the throne; but his conduct was such as to cool the ardour of his friends, and to excite enmity and opposition. In procès of time, from the year 366 to 369, he contended successfully with the Goth, and having reduced them to great distress, promised to conclude a treaty with them, which was ratified with great magnificence in bargains upon the Danube. Having accomplished this object, Valens returned in triumph to Constantinople.

Valens, having received his Christian creed from Eudoxus, the Arian bishop of Constaninople, disgraced himself by becoming a persecutor of the Athanasians: and in a contest between these two parties, he acted in a manner so rigorous and violent, as to entail indelible reproach on his memory. In 371 he left his only son, and in the following year he defeated the Persians, and afterwards readily consented to a truce. Whilfe he was passing the winter at Antioch, in the year 374, he manifested, in his treatment of persons who recurred to magical practices for ascertaining the name of the future successor to the imperial throne, the jealous cruelty of his character. Many pernian were involved in real or suspected guilt, and configned to the punishment of torture, banishment, or death. Having rehired five years at Antioch, watching the motions of the Persian king, repressing the incursions of the Saracens into the south of Hauran, and conducting land inquisitions and religious persecutions, his attention was excited by a terrible inundation of the Huns upon the territories of the Visigoths, and the Huns, having obtained permission to cross the Danube, penetrated into the cultivated part of Thrace. The Gothic tribes were joined by the Huns and Alans. The emperor arrived at Constaninople in 378, and urged by the clamours of the people, marched against the enemy to the vicinity of Constaninople. An engagement ensued, which proved singularly fatal to the Romans. Valens, defeated by his guards and wounded, betook himself to a cottage, in which his attendants were dressing his wound: the cottage was beset by the enemy, who being refilled, set fire to a pile of faggots, that consumed the emperor and all that were with him. Thus did Valens terminate his life at the age of fifty, and in the sixteenth year of his reign. His character, as it has been delineated by historians, merits in many respects contempt and detestation. He was nevertheless modest and temperate in his mode of living; addicted to no private vice or superfluous expense; ready to listen to the complaints of his subjects, and to protect them from the oppression of the military, among whom he preferred exact discipline; and it has been said that the Eastern provinces in general were never happier than under his government. Auc. Un. Hist. Gibbon's Rom. Emp. Gen. Biog.

VALENSELLE, in Geography, a town of France, in the department of the Lower Alps; 18 miles S. of Digne.

VALENTANO, a town of the Popedom, in the duchy of Caltro; 14 miles S.W. of Orvieto.

VALENTIA, in Ancient Geography, a town of Hispania Citerior, upon the Tauria. See Valencia.

VALENCIA, a town and colony of Galla Narbonensis, belonging to the Suebians, according to Pomponius, but to the Cavares, according to Pliny. In the Itinerary of Antonine, this town is marked on the route from Mediolanum to Lugdunum, between Augustula and Urfares. At the fall of the Roman empire this town became subject to the Burgundians, afterwards to the Merovingians; but under the Carolingians, it belonged to the kingdom of Burgundy and Arles. — Alfo, a country of the isle of Albion, according to Amianus Marcellinus. It was conquered by Theodosius the elder, and made a fifth Roman province. (See Otoilli.) — Alfo, a town of Italy, in Messapia, between Cipae and Civitas Brundii, according to the Itinerary of Jerusalem. — Alfo, a town situated in the interior of the isle of Sardinia.

VALENTIA, in Geography, a small island on the coast of A. Kerry,
Kerry, Ireland, in the barony of Inveragh, from which it is separated by a channel, which is a safe harbour. Though Valentia contains extensive bogs, it has more inhabitants and better culture than could be expected in so remote a spot; it is indeed esteemed the granary of the country. Oliver Cromwell had forts erected at both ends of the channel, which have gone to ruin. Valentia is the property of the marquis of Lansdowne. Its northern point is in N. lat. 51° 54'. W. long. 10° 10'.

**VALENTIA**, a bay of Ireland, on the eait side of Dingle bay, between the isle of Valentia and Dowlas Head.

**VALENTIAM.** See Cape ad Valentinam.

**VALENTINE, Peter,** in Biography, was born at Coloniers en Bric in 1600, and studied some time under Simon Vincent, but leaving that matter before he had made any considerable progress, travelled to Rome, where he passed the remainder of his life: he may therefore be rather considered of the Roman than the French school. The powerful and vigorous style of Michael Angelo Caravaggio made more impression on him, that he attached himself to an imitation of it, with a devotion that was never diminished. Like that artist, he indulged in an extravagant, but effective contrast of light and shadow; like him, he was a faithful follower of nature, and was equally indifferent and unfortunate in his choice of it; like him, he was frequently incorrect, and always ignoble. He was, however, an intelligent master of the chiaro- scuro, and his mafles are disposed so as to produce the most striking effect. Though he occasionally painted altar-pieces for the churches, his powers appear to have been better adapted to other subjects, which he also appears to have painted in preference. His bell pictures represent fortune-tellers, gamblers, concerts of music, and corps de gardes; to which his taste was more competent than to the dignity of historic painting. The patronage of cardinal Barberini, nephew to Urban VIII., procured him the commission to paint a large picture for the Basilica of St. Peter, representing the Martyrdom of S. S. Procceo e Martiniano, which is esteemed his bell historic painting. He also painted for his patron, the Decollation of St. John, in the Palazzo Barberini; and there is an admired picture by him in the Corsini palace, of Peter denying Christ. This pleasing painter died in 1632, at the early age of thirty-two, of a fever, being brought on by going into a cold bath when he was heated.

**VALENTINE,** in Geography, a town of France, in the department of the Upper Garonne; 2 miles S.W. of St. Gaudens.

**VALENTINE'S Bay,** a bay on the south-east coast of Terra del Fuego, west of Cape Succes.

**VALENTINI, Michael Bernhard,** in Biography, a native of Gieffen, in Germany, where he was born in 1657, and became a medical professor, and where he died in 1729. The subjects of his writings, which are numerous, chiefly comprehend botany and the materia medica: of these we shall here mention his "Letters from the East Indies;" "Praxis Medica," in two parts; "Amphitheatrum Zoetomium," fol.; and a "Corpus Juris Medic旅行-legalis," fol. referring for other works to the botanical article VALENTINI." Haller.

**VALENTINI, Pietro Francesco,** of Rome, who flourished about the year 1645, and whose patience and abilities in the construction of canons seem to have made every frequent canoniist despair of emulating his subtilty and dexterity in the art. Indeed he appears to have surpassed all that the most determined canoniists had ever achieved, by the several works which he published on the subject, in the following order: "Canon to the words Illas tuas miser;" "Canon to the words odos ad nos concerta," with the Resolution in more than two thousand ways, for two, three, four, and five voices, Rome, 1629;" "Canon, called the Knot of Solomon, for ninety-six voices, Rome, 1631;" "Canon on four Subjects for twenty voices, Rome, 1643." The first and most curious of these works seems to have been reprinted in 1655, as M. Marpurg of Berlin, and several other musical writers, in speaking of it, refer to an edition of that date. But P. Martini, who is in general very accurate in dates and citations, mentions Valentinii's first canonical work under the year 1629. Kircher gives the subject, and an account of this canon, in his Mufurgia. M. Marpurg, in a periodical work called Strittf 6st Wittte, or "Critical Letters on the Art of Music," vol. ii. 1763, 4to, has bestowed upwards of fifty pages on this canon, and not only given it a hundred different ways in notes, but explained more than two hundred of the several contrivances used by Valentinii in the construction of canons on the subject given.

Numerous musicians of the name of Valentinii have been recorded by musical writers; among whom Gerber gives an article to a nameake of the canonist, Pietro Francesco Valentinii, an opera composer at Rome in the middle of the seventeenth century, who, besides Intermezzi, set to music several dramatic fables written by good poets, such as "La Metra," a Greek fable; "The Death of Orpheus;" "Pythagoras finding Musical Proportions," 1654; "The Transformation of Daphne," a moral fable. His Intermezzi were the Rape of Proserpine, and the Captivity of Mars and Venus in the Net.

**VALENTINI, Roberto,** an Englishman, a voluminous composer for the common flute, whose works were chiefly published by Roger, at Amsterdam.

**VALENTINI, Giuseppe,** about the latter part of the seventeenth century, among other composers for the violin, a dozina, published in Holland nine different works for that instrument, the seventh and last of which were "Concerti Grossi," for four violins, tenor, and two basses; but they have been long since configned to oblivion, without any loss to the public, or injustice to the author.

**VALENTINI, Urbani,** the first soprano opera singer who appeared on our stage, arrived in England 1707, after the attempts that were made at opera upon the Italian model.

**VALENTINIA, in Botany,** received that appellation from Dr. Swartz, in memory of two writers of the name of Valentinii, who have both of them contributed to the general stock of botanical information, particularly with relation to the Materia Medica. Michael Bernard Valentinii, professor of medicine at Gieffen, who died in 1729, aged 72, published Prodrumus Historiae Naturalis Hafne, in 1707, Viridarium Reformatum, in 1719, Museum Mycorum, in 1704, and Histioria Familiarum Reformata, printed at different times; besides several dissertations, illustrative of the natural history of Sago, Cloves, Nutmegs, Pepper, Cinnamon, Dates, Alces wood, &c. His son, Christopher Bernard Valentinii, published Tournefortii Consuetudines, being an arrangement of Tournefort's Influstiones in the form of tables; with some other works.—Swartz Prodr. 64. Ind. Occ. 687. t. 184. Schreb. Gen. 801. Wildl. Sp. Pl. v. 2. 344. Mart. Mill. Dict. v. 4.—Clas and order, Ophionia Monogynia. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth inferior, of one leaf, concave, colour in five deep, nutate, concave, spreading, univalved segments. Car. none, unless the calyx be taken for such. Stam. Filaments eight, awl-shaped, erect, rather shorter than the calyx; anthers roundish. Fil. Germien superior, roundish; style one, the length of the filaments, thick, cylindrical; stigma
stigma capitate. *Peric.* Capsule pulpy, roundish, burting into three or four revolute valves, juicy within, of one cell. 

*Seeds* four, oblong.

Eff. Ch. Calyx coloured, in five deep spreading segments. Corolla none. Capsule inferior, pulpy, of one cell, and four seeds.

1. *V. thistrifolia.* Holly-leaved Valentinia. *Swartz* Ind. Oec. 680. Wild. n. 1. (Malpighia aquifolii amplifolius folia; Pluck. L. 167. f. 2. Ilex folio aquifolii americana; Pluck. Phyt. t. 195. f. 3.)—Native of the most barren ftony parts of Hifpamols, towards the ocean; also of Cuba, about the Havana, flowering in January. A *frub,* two or three feet high, branched, of a rigid habit, without thorns; the branches smooth. *Leaves* alternate, oblong, rigid, flaked, with axillary buds; their length three or four inches; their breadth more than one; their margins undulated, and beft with broad spinous teeth, like our common Holly; both surfaces smooth and veiney. *Flowers* at the ends of the branches, flaked, somewhat umbellate, scarlet. *Calyx* permanent. *Fruit* in an earlyflate snow-white, afterwards scarlet. *Seeds* three or four, smooth, imbedded in yellow pulp.—Burmann, with more of his usual fagacity, fuppofed this plant was not really *Malpighia,* because of its alternate leaves. Dr. Swartz thinks it belongs to the fame natural order as *Ilex,* but the want of a corolla, and the structure of the fruit, caufe fome difficulties.

VALENTINIAN I., in *Biography,* a Roman emperor, defended from an obscure family of Cithalis, in Pannonia, and born A.D. 321. Dedicated to the profefion of arms, he distinguiflied himfelf by attention to military discipline, and in the reign of Conftantine commanded a body of cavalry in Gaul. Under Julian he was tribune of one of the bands of imperial guards, and played his zeal for the Christian religion. On the accession of Jovian, he ferved in Gaul; and returning to the East, he was at Ancyra at the time of Jovian's death: and here he was raised to the purple by general ap- plaufe in 364, in the 43d year of his age. On his arrival at Conftantinople, he declared his brother Valens his partner in the empire. On the division of the empire (see VALENS), he referred to himself the western portion, confifiting of Illyricum, Italy, Spain, Gaul, Britain, and Africa. After this event he refided at Milan. Soon after, his reign was difturbed by an irruption of the Alemanni into Gaul. In 368 he crofed the Rhine with a powerful army, and having forced the camp of the Alemanni, he returned to Trecos, and fortified the banks of that river, so that Gaul was fe- cured from any danger during the remainder of his reign. The spirit of his government was that of vigorous discipline; and till he was corrupted by power, he paid a regard to justice and the public good; enacting many fa- luntary laws in favour of the poor and defecrated, providing for the instruction of youth, and exercifing toleration in matters of religion. Accordingly he allowed unmolefted liberty to Jews and Piftans, whilst he procribed magical rites, and punished thofe who practifed them. He also restrained the avarice and luxury of the clergy, and declared donations, that were injurious to families, illegal; and proceeded fo far as to incapacitate all persons of the ecclefiafical order from receiving any defamation bequeath, except fuch as came to them by inheritance.

Valentinian was rath and violent in his temper, and liable to be impofed upon by his迷你lers and officers. Among the other events of his reign, we may mention an invasion of the Alemanni by the Burgundians, at his {efigation;} the predatory incursions of the Saxons on the maritime provinces of Gaul; and the recovery of the Roman province in Britain from the invasion of the Picts and Scots. Being en-
camped near Bafl, in 374, he received intelligence that the Quadi had entered Pannonia, and that the Sarmatians had in- vaded *Mafia*; he advanced to the Danube, and crofing that river, laid waife the country of the Quadi with fire and fword. When the Quadi rebelled for peace, he menaced and re- proached them with fuch an excess of paffion, that he broke a blood-vefel, and fell fpeechlefs into the arms of his attend- ants. This difalter was foon followed by his death, which happened in 375, in the twelfth year of his reign, when he attained the age of about fifty-four years. The historian *Soates* affirms that he had two wives at a time, infufling an edict that extended the fame privilege to all his fubjefts. But this circumstance has been doubted, as no laws moin- ent with the religion and manners of the period in which he lived, than with his own difposition and character, for he does not seem to have been addicted to licentious pleasures. Hab- bituating himfelf to fenes of torture and death, he at length took delight in them; and he is faid to have kept two enor- mous bears near his perfon, which he employed as executioners, for his private amusement. Upon the whole, however, his government was beneficial; and whilst he defended the empire with vigour, he promoted its reputation and prosperity by good laws and useful institutions. Anc. Un. Hist. Gib- ton's Rom. Emp. Gen. Biog.

VALENTINIAN II., a Roman emperor, was the fon of the former by the empress Jufrina, and born in 371. On the death of his father, when his half-brother Gratian, his partner in the empire, was at a diftance, he was declared emperor by the principal ministers and officers of his deceased parent, and Gratian acquiefced in the appointment. His portion of the empire comprifed Italy, Illyricum, and Africa. As his mother was attached to the Arian fect, he was involved in a contref with Ambrofe, archbishop of Milan, and thus the people became defaified to her fon; fo that upon the death of Gratian, the usurper Maximus invaded Italy, and obliged Jufrina and Valentinian to take refuge in Aquileia. Hence they proceeded to Thelfalonia, and implored the affiftance and protection of Theodofius, emperor of the East. Theodosius having prevailed with Valentinian to renounce the Arian doctrine, promifed to support his caufe, and the confquences of his interpoftion were the defeat and death of Maximus, in the year 388. Upon this the young emperor was refored to his dominions; and difplayed thofe virtues which ferved to gain him the eulogy of Ambrofe and other ecclefiafical writers. Such was his religious zeal, that he refufed to grant the to his pagan subjects a reforation of their privileges to the heathen priests and temples. Whilst Valentinian was at Vienne, in Gaul, the barbarians on the frontiers of Italy threatened an invasion; but the emperor, before he exposed himfelf to the hazards of war, determined to be haptized, and fent for Ambrofe to administer the rite. He also volufed to engage the prelate's mediation with Arbo- gastes, the Frank, who had affumed an almost uncontrofled power over the government. He also fough the affiftance of Theodofius. In the mean while he received Arbogastes, whilk he was feated on his throne, and delivered to him a paper, expressing his difaffidion from all his employments. The Frank told him that his authority did not depend upon the will of a monarch, and threw the paper contemptuously on the ground. Valentinian was enraged, and attempted to avenge himfelf by wretting a fword from one of his guards; but his violence was reftrained. However, a few days after he was found hanged in his apartments, May, A.D. 392, being then in his twenty-fifth year, and having nominally reigned 16 years. Anc. Un. Hist. Gib- ton's Rom. Emp. Gen. Biog.

VALENTINIAN III., a Roman emperor, the fon of Pla-
old, filter of the emperor Honorius, by Constantius, one of that emperor's generals, who was born in the year 418, and after the death of Honorius, declared emperor of the West. In 437 he was married to Eudoxia, the daughter of Theodorus II, but during the life of his mother, who died in 450, he took no part in the government. The death of Attila caused him to retire from Ravenna to Rome, where he proposed terms of accommodation with this formidable enemy, which were accepted. The weaknesses and timidity of this emperor occasioned a jealousy of the famous general Actius, and base measures were secretly concerted for putting him to death. Valentinian himself perpetrated the foul deed of his affimation: and this act was followed by the murder of several of his friends. This detestable act, which took place in 454, was succeeded by the violation of the chaste and beautiful wife of Petronius Maximus, a wealthy senator. Her husband, as soon as he was informed of it, determined upon revenge; and for this purpose engaged two of the imperial guards who had served under Actius. One of these seized the opportunity of some military sports in the Campus Martius to flab the emperor to the heart. This event happened in March 455, when Valentinian was thirty-four years of age, and after he had borne the title of emperor twenty-two years. He was the last emperor of the race of Theodorus, and had all the weaknesses, with none of the virtues of that line. Anc. Uni. Hist. Gibbon. Gen. Biog.

VALENTINIANS, in Ecclesiastical History, an ancient and famous sect of Gnostics; thus called from their leader Valentinus, an Egyptian by birth, who was eminently distinguished by the extent of his fame, and the multitude of his followers. His sect, which took rise at Rome towards the close of the second century, grew up to maturity in the isle of Cyprus, and spread itself through Asia, Africa, and Europe, with amazing rapidity. His principles were much the same with those of the Gnostics, though, in many respects, he entertained opinions peculiar to himself. He placed in the pleroma, as the Gnostics called the habitation of the deity, thirty zeus, half male and half female: to these he added four others, which were of neither sex, viz. Horus, Christ, the Holy Ghost, and Jesus. The youngest zeus, called Sophia, or Wisdom, conceived an ardent desire of comprehending the nature of the Supreme Being, and by the force of this propensity, brought forth a daughter named Achamoth; who being expelled from the pleroma, fell down into the unglodified mass of matter, and arranged it; and, by the affidavit of Jesus, produced the demiurge, the lord and creator of all things. This demiurge separated the animal from the terrestrial world; and out of the former created the superior world, or visible heavens; and out of the latter, the inferior world, or the terraqueous globe. He also made man, uniting in his composition the animal and terrestrial matter, to which Achamoth added a spiritual and celestial substance. The demiurge, according to Valentine, arrogating the honours of God alone, sent prophets to the Jewish nation to urge his claims; and his ambition was imitated by the other angels that preside over the different parts of the universe. In order to chastise this lawless arrogance, and to illuminate the minds of rational beings with the knowledge of the true and supreme Deity, Christ appeared on earth, composed of an animal and spiritual substance, and clothed, moreover, with an aerial body. The Redeemer, in descending upon earth, passed through the womb of Mary; and Jesus, one of the supreme zeus, was united to him when he was baptized by John in Jordan. The creator of this world, perceiving that the foundations of his empire were shaken, caused him to be apprehended and nailed to the cross; but before Christ submitted to this punishment, not only Jesus the Son of God, but the rational soul of Christ, ascended up on high; so that only the animal soul and the ethereal body suffered crucifixion. Those who, abandoning the service of false deities and the worship of the God of the Jews, live according to the precepts of Christ, and submit the animal and ethereal soul to the discipline of reason, shall be truly happy; and when all the parts of the divine nature, or all souls, are purified thoroughly and separately from matter, then a raging fire shall spread its flames through the universe, and dissolve the frame of the corporeal world. Such is the doctrine of Valentine and the Gnostics; and such, in general, are the tenets of the oriental philosophy. The sect of the Valentinians was divided into many branches. See Ptolemaiots, Secundians, Heracleontites, and Marcionists. Moehlmann's Ecc. Hist. vol. III.

VALENTINUS, the founder of a sect of heretics, for an account of which, see VALENTINIANS.

VALENZA, in Geography, a town in Italy, in the department of the Gogno, on the Po; 6 miles N. of Alexandria.

VALEPONGA, in Ancient Geography, a town of Hithapania Citerior, at the eastern foot of mount Ubeda, near the source of the river Turia. In the Itinerary of Antonine it is marked on the route from Laminium to Toletum, between Ad Putea and Uribaca.

VALERE. See PERINDE VALERE.

VALERIA, VALERA, in Ancient Geography, a town in the interior of Hifpania Citerior, S. of Ergavia. Pliny reckons it in the number of colonies, and Ortelius gives it the epitaph of Julia. It was situated in Celtiberia, E. of Sueco, and W. of Lobetum.—Alfo, a town of the ile of Forica, which had the title of a colony, according to Ptolemey.—Alfo, a country of Germany, comprehending a part of Pannonia, and so called by Maximian, after the name of Valeria, his wife, the daughter of Diocletian. It was situated between the Danube and the Drave.—Alfo, the thirteenth province of Italy, to which Nurtia was annexed. It was between Umbria, Campania and Picenum, and comprehended the country of the Marsi and their lake, called "Lucus."—Alfo, a town of Italy, in Latium, on the Valerian way.

VALERIAN, P. LICINIUS VALERIANUS, in Biography, a Roman emperor, the descendant of an illustrious family at Rome, was betimes so distinguished by his attention both to civil and military affairs, that he was appointed consul and prince of the senate, and also cenfor. He occupied other stations of considerable trust and importance. At length his own troops proclaimed him emperor, in which choice every individual of the empire was diffpoused to concur. Accordingly he was invested with the purple A.D. 253, after having palled his sixtieth year. The commencement of his reign was rendered illustrious by many popular and laudable acts, from which eulogy, however, we must except the appointment of his son Gallienus, a vicious youth, to be his colleague in the empire; more especially as in the progress of it he had many enemies with whom to contend; among whom we may enumerate Fraunks, Goth, Allemane, and Perians, the latter of whom may be deemed the most formidable. When Antoninus was surprized and pillaged, under the indignation of Sapor, king of Persia, by Cyriades, who assumed the title of emperor, Valerian marched to the restitution of this city, and having expelled the Scythisans, who had taken possession of it, he hastened to cross the Ephorus, in order to relieve Edessa, which was besieged by Sapor. After a vain attempt for this purpose, he was reduced to the necessity of negotiating with the Persian king. The result, however, was, that
that he became a captive to Sapor, A.D. 260, and was treated cruelly and ignominiously in his captivity. This diff- 
tre was aggravated by the ingratitude of his fon Gallienus, who afforded him no relief in his captivity, but took advan-
tage of a report of his death to raise him to the rank of a 
' After languishing in this state for a considerable time, he 
died in Peræa; and it was rumoured, that after his death, his 
kins, stuffed with straw, was hung up in a temple, where 
Sapor exhibited it as an humiliating spectable to the ambas-
dadors from Rome. Valerian, whose administration was 
charged with want of vigour and activity in resisting the 
forces of the east, was not unjustly reproached as a perfe-
cutor of the Christians. Regarding them as the enemies of 
paganism, he issued an edict, which produced the eighth per-
fection, as it has been called by ecclesiastical historians, and 
which was both general and severe, and lasted from the year 
257 to the period of his captivity. The calamities which he 
suffered has been represented as a judgment upon him for 
this cruelty. He was twice married, Gallienus being the 
offspring of the first marriage; and by the second he had at 

VALERIANA, in Botany, a name which seems to have 
originated with the physicians of the dark ages, and which 
is evidently derived from valea, to be powerful, or efficacious, 
in allusion, as Caspar Bahum and Ambrofius tell us, to the 
many virtues of the plant. Linneaus, in Phil. Bot. 171, 
unaccountably ranks this name among those derived, like 
Gentiana, Eupatorium, &c. from kings.—Linn. Gen. 22. 
Garcke, t. 86.—Cals and order, Triandria Monogynia. 

Gen. Ch. Cal. scarcely any, except a flight border at the 
top of the germin. Cor. of one petal, irregular; tube 
swelling, or spurred, underneath the base, where it bears 
honey; limb in five obtuse segments. Stam. Filaments three, 
in some cafes fewer, awl-shaped, erect, the length of the 
corolla; anthers roundish. Fil. Germin inferior; style 
thread-shaped, the length of the stamens; stigma thickish. 
Peric. a crust, which does not split, deciduous, crowned. 
Seced solitary, oblong.

Eff. Ch. Calyx's obsolete. Corolla superior, of one petal, 
gibbous on one side, at the base. Seced solitary.

Obf. Linneaus remarks as follows on the wonderful 
diversitys of form and number in the parts of fructification, 
among the various species of this genus:

The calyx in some is a scarcely discernible border; in 
others five-creft. Tube of the corolla in some oblong; in 
a few furnished with a four-spurred corolla; in others very 
short. Its limb in some equal; in others two-tipped, the 
upper lip divided. Stamina in several three; in some two; 
in others one or four; in some removed to a different flower 
from the pitif. Sygma in some three-creft; in others emar-
ginate; in others globous. Pericarp in some fecezly any; 
in others a thick capulce; in others of two cells. Seced 
sometimes crowned with feathery down, whose form is 
various; sometimes without any.

By the above detail, the reader will be aware that Lin-
neaus includes under this genus the Fedia of Adamon, (see 
that article,) which is what Tournefort, Vaillant, and 
recently Decandolle, have called Valeriana. The same 
genus is adopted, under the late-mentioned name, by our 
worthy friend Mr. W. J. Hooker, in his continuation of 
Curtis's Flora Loddigesiana. Such diminutives of already 
established names, however, being contrary to the laws of 
Linneaus, Phil. Bot. f. 227 and 228, and, which is still 
more important, repugnant, in the highest degree, to good 
form, have never been admitted by any writer, even the left 
correct, since Linneaus has from unamalgulated sound principles of 
nomenclature, and can have been recommended by the 
excellent botanists, through inadvertence only. Fedia is, 
unexceptionable, and received by Vahl in his Enumeratio, 
must supercede Valeriana, provided the genus is allowed 
to remain, of which we have already expressed our doubts. 
We have indeed little scruple, all things considered, in 
rejecting it. (See our 33d, 45th, and following species.) 
But having already noticed Fedia in its proper place, we 
shall here confine ourselves to the generally admitted Val-
eriana, which constitute an ample genus, recently augmented 
by Vahl, whose arrangement of species we follow, from the 
Flora Peruviana, and other sources; to which we have also 
something to add.

The genus under consideration is composed of herbaceous 
plants, either perennial or annual, with an upright round 
flam, and opposite leaves; which are mostly simple; rarely 
ternate or, pinnate. Flowers terminal, numerous, opposite, 
corymbose or panicled; generally reddish, or flesh-coloured; 
rarely yellowish; fearfully blue. The roots of some are 
distingueed by a more potent and very peculiar odour.

(V. rubra Dodonaei; Ger. Em. 678. V. marina; Rivin. 
Monop. Irr. t. 3. f. 2. Phu peregrinus; Camer. Epit. 24.)

—Stamen one. Spur of the flower elongated. Leaves lan-
ccolate, nearly entire.—Native of walls, wall ground, 
chalk-pits, and dry hilly places, in England, Switzerland, 
France, the north of Africa, Greece, and other parts of 
the Levant. Certainly wild in the chalk-pits of Kent; 
flowering from June to September. The plant is common 
in gardens, and on old walls. A deep red variety is usually 
preferred for cultivation. The root is perennial, flat, or 
ther middity. Whole herb very smooth, a little glaucous, 
eighteen inches or two feet high. Upper leaves often 
toothed, broadly ovate, with a long point. Flowers pink, 
rarely white, slender, not inelegant, very numerous, in 
a dense repeatedly branched corymb. Seed-crown of many fe-
athery entangled rays, gradually unravelled after the flower is 
past.

n. 2. Vahl n. 2. Alt. n. 2. Cavan. Ir. v. 4. 32. t. 353. 
Sm. Fl. Græc. Sibth. v. 1. 22. t. 29. (V. rubra; Linn. 
Sp. Pl. 44. V. rubra angulifolia; Buhl. Hill. v. 3. 
part 2. 211.)—Stamen one. Spur of the flower elongated. 
Leaves linear-lanceolate, bluish, entire.—Native of hilly 
situations in France, Italy, Switzerland, and the Levant, 
but not yet observed in England. Dr. Sibthorp gathered 
it on the highest hills about Athens. This is very nearly 
related to the former, with which it agrees altogether in 
habit and flowers, but the leaves are all uniformly narrow, 
almost linear,quite entire, and more obtuse at the ex-
tremity.

44. Willd. n. 3. Vahl n. 3. Alt. n. 3. Sm. Fl. Græc. 
Sibth. v. 1. 22. t. 30. (V. folia calcitrapa; Morif. lect. 7. 
t. 14. f. 7. V. amma, fen adula; Chaf. Hist. v. 2. 54. 
Ger. Em. 1077.)—Stamen one. Corolla flatly spurred. 
Leaves all pinnatifid and feathery.—Native of Portugal, the 
north of Africa, the Levant, and even of Peru; but Vahl justly 
supposes its having been transported thither from Europe. 
It became a weed on many walls of that nation; having, 
due to the climate, escaped from the physic garden there. An 
Annual upright herb, fearlessly branched, flowering in May 
and
and June; the leaves slightly lyrate; flowers small, rose-coloured. Seeds spiked, with a feathery crown.

4. V. orbiculata. Round-leaved Valerian. Sm. Fl. Grac. Sibth. v. 1. 23. t. 31, marked retundifolia.—Stem one. Corolla slightly spurred. Lower leaves stalked, orbicular, somewhat heart-shaped, slightly toothed.—Gathered by Dr. Sibthorp and Mr. Ferdinand Bauer, on hills in the Isle of Cyprus, flowering in the spring. Annual, and agreeing in habit with the late, but of rather humber growth, and essentially distinguished by its round leaves, hardly an inch broad, purple beneath; the uppermost pair only being pinnatifid at their base. Flowers variegated with red and white, in twinline spikes, much elongated as the seeds ripen.

5. V. oblongifolia. Oblong-leaved Valerian. "Fl. Peruv. v. 1. 40. t. 65. f. a." Vahl n. 4.—"Hairy. Radical leaves oblong, toothed, obtuse; those of the stem linear, with tooth-like deep ferratures."—Found on the lofty mountains of Peru. Root fibrous, rather thick. Stems several, frigate, almost leaflets, except under the flowers; the central one tailed, eighteen inches high. Radical leaves stalked, diitantly toothed; the floral ones leaflet, linear-lanceolate. Flowers leaflet, in a dense corymb. Vahl.

7. V. Ph. Garden Valerian. Linn. Sp. Pl. 45. Wildl. n. 7. Vahl n. 6. Ait. n. 6. (V. hortense; Ger. Em. 1075. Rivin. Monop. Irr. t. 3. Phu magnitude; Puch. Fl. 856. Matth. Valgr. v. 1. 36.)—Radical leaves elliptical, undivided; the root pinnatifid, somewhat lyrated; the upper ones with lanceolate, acute, entire segments.—Native of Germany. An old inhabitant of our gardens, where it was anciaently called Setwall, or Cettivial. A large perennial species, flowering from May to July. Stems three or four feet high. Herbaceous smooth, light green, with spreading leaves, mostly lyrate, except those at the bottom. Flowers copious, pale purplish-blue-coloured. The flexible root has a peculiar aromatic scent, and is supposed to partake of the virtues of the Office Valerian. Cats are extremely fond of it, and delight in rolling themselves among the leaflets and leaves, which they thus frequently defray.

8. V. hyalorinorhiza. Transparent-rooted Valerian. "Fl. Peruv. v. 1. 41. t. 67. f. b." Vahl n. 7.—"Radical leaves roundish-filipatulate, crenate, undivided or auricled; those of the stem pinnatifid."—Found in dry sandy parts of Chile. Herb downy. Root tuberous, obovate, pellucid, infipid. Stems half a foot high, purplish. Radical leaves stalked; the innermost with an additional leaflet at each side; those of the stem diffus, connate, lanceolate. Corymb forked. Calyx obample. Corolla yellow. Seed square, crowned with minute teeth. Vahl.

9. V. crista. Curled Valerian. "Fl. Peruv. v. 1. 41." Vahl n. 8.—"Lower leaves ovate-oblong, with tooth-like ferratures; the root somewhat pinnate, with ferratted undulated leaflets."—Native of meadows, fields, and cultivated ground, in Chili. Root with many small fibres. Stems two feet high, branched, brittle, frigate, hollow. Leaves stalked; those of the stem more or less perfectly pinnate; their leaflets feffile, reflexed, wavy and crispated, gradually smaller downward; the odd one very large. "Chihuy forked. Vahl.

10. V. interrupta. Interrupted-leaved Valerian. "Fl. Peruv. v. 1. 42. t. 67. f. a." Vahl n. 9.—"Radical leaves interruptedly pinnatifid; their longer segments also somewhat pinnatifid. Stem nearly leaflets."—Found on the lofty mountains of Peru. Root perennial, thick, divided. Herb juicy and smooth. Leaves all radical, except a pinnatifid pair under the corymb, not much unlike those of Scorzonera laciniata. Stalks terminal, three together, each bearing a head of feffile flowers, with linear bracteas to each. Corolla white, five-cleft. Vahl.

11. V. lyrica. Lyrate Valerian. Vahl n. 10.—"Radical leaves lyrate; segments oblong, with tooth-like ferratures; the terminal one somewhat pinnatifid; those of the stem leaves linear-lanceolate."—Native of Peru; seen by Vahl in Jullieu's herbarium. Stem smooth, a fpan high, bearing two leaves. Radical leaves stalked, half the length of the stem; their terminal lobe very large, measuring two inches; lateral ones alternate; deeply and bluntly ferrated; stem leaves feffile, half an inch long; all smooth. Partial flowers stalks racemose, three-cleft, forked. The aspect of the plant is like V. calcitrare. Vahl.

13. V. globifera. Globular-headed Valerian. "Fl. Peruv. v. 1. 43. t. 65. f. b." Vahl n. 12.—"Hairy, fmemelles. Leaves pinnate; leaflets deeply toothed or frigate. Heads globose."—Native of the high mountains of Peru. Root rather thick, once or twice divided. Leaves radical, frigate, with fettile leaflets. Flowers stalks several, radical, frigate, with fettile leaflets. Flowerstalks several, radical, measuring four or five inches, scarcely longer than the leaves, round, frigate. Flowers fettile, in a globular head, with intermediate fpatulate, rather membranous, bracteas. Vahl.

15. V. polyphylla. Many-spiked Valerian. Sm. Pl. 1c. t. 51. Wildl. n. 19. Vahl n. 14.—Leaves pinnate; leaflets decurrent, nearly entire. Spike compound, whorled. —Gathered by Commeron, in watery situations at Buenos Ayres. Stem two feet high at leaf, ascending, frigate, smooth, leafy. Leaflets smooth, nearly uniform, about an inch and half long; the odd one now and then slightly toothed; the lowermost much diminished. Flowers white, very numerous, in dense cipious awholes, subtended by lanceolate
VALERIANA.

colate bracteas, and forming a compound spike, not unlike that of some Mentha. It is doubtful whether the seed has any feathery crown.

16. V. officinalis. Great Wild Valerian. Linn. Sp. Pl. 45. Willd. n. 6. Vahl n. 15. Ait. n. 5. Fl. Brit. n. 3. Engl. Bot. t. 698. Curt. Lond. facs. t. 3. Woodward. Med. Bot. t. 96. Fl. Dan. t. 570. (Valeriana; Rivon. Monop. t. 1; and V. foliis angustibus; ibid. t. 2. V. major fylvefris; Ger. Em. 1075. Piit.; Column. Phytob. 114. Ph. parvum; Matth. Valgr. n. 377. Ph. minus; Cramer. Epit. 22. Ph. germanicum; Fuech. Hift. 837.)—Leaves all pinnate; leaflets lanceolate, ferrated, nearly uniform. Common in marshy places, the banks of rivers, or hilly groves and thickets, flowering in June, throughout the more northern parts of Europe. Root perennial, fibby, aromatic, but with a strong and peculiar, very nauscent, flavour, highly grateful to cats. Stem about four feet high, furrowed, leafy. Leaves forked, from eight to twelve inches long; leaflets of the radical ones, in the upland variety, somewhat broader, and more ovate, than in the marsh kind; while those of the stem, in the same variety, are sometimes very narrow and entire. Flowers numerous, flesh-coloured or white, in large corymbose tufts. Seed crowned with large feather down.

This plant having, till very lately, seen no specimens, has been generally taken for the famous 560, or Valerian, of Dioscorides, and has been universally employed in medicine, for the cure of nervous head-aches, hysterical and epileptic disorders. The mountain kind, being less acrid and more aromatic, is preferred for use, and is kept in all apothecaries' shops, in whose "compound of villaneous smell" its flavour notably predominates.

17. V. Dioecoides. Ancient Grecian Valerian. Sm. Fl. Grac. Bibth. v. 24. t. 33. (Ph; Diosc. book 1. chap. 10.)—Stamens three. Leaves all pinnate; leaflets of the lyrate radical ones ovate, with wavy teeth. Root tuberous.—Gathered by Dr. Sibthorp near the river Lycia, as we are informed by Mr. Hawkins, the learned companion of his tour. The professor himself riffs, of all modern botanists, discovered this plant, and justly concluded it to be the real 560, for which our common wild Valerian has been always mistaken. The oblong tuberous perennial root has a much more pungent, peppery, more durable, and yet less nauscent, odour than the last described. The stem is hollow, simple, two feet high. Herb smooth. Radical leaves numerous, lyrate, disfigured by the ovate form, and wavy margin, of all their leaflets, of which the one odd is much the largest, and somewhat heart-shaped: those of the stem few, lanceolate, narrow, partly ferrated. Flowes very like the last.

18. V. italia. Italian Valerian. Lamarck Illutrit. v. 1. 92. Vahl n. 16. (V. tuberoa; Imperatio Hist. Nat. 656. Bauh. Hist. v. 3. part 2. 207. V. tuberoa Imperati; Tourn. Cor. 5. Barcel. Ic. t. 825. V. zenanthes radice; Moril. fecr. 7. t. 15. f. 4.)—Stamens four. Leaves all pinnate; leaflets of the radical ones ovate, nearly uniform, sharply toothed. Root tuberous.—Gathered by Imperato on the mountains of Liguria. We have only his figure, which all authors have copied, to guide us; except Vahl's description, made from a specimen in Jussieu's collection. This appears very nearly the same with our V. Dioecoides, especially the root, which is said to smell like Nard. The leaves however are represented as much more strongly toothed, more equally pinnate, and not lyrate; the upper pair indeed have narrow entire leaflets, remmbling our last. The flowers are white, more densely corymbose, and affected by Lamarck to have four flanneas, which, if correct, and contrast, indicates an essential difference. It would be very defrable to compare specimens of this Italian Valerian with those of Dr. Sibthorp.

19. V. fimbriifolius. Water-cresc-leaved Valerian. Vahl n. 17. (V. orientalis, fimbrii Matthioli folio; Tourn. Cor. 6.)—"Leaves all pinnate; leaflets roundish-ovate, entire."—Native of the Levant; examined in Jussieu's herbarium by Vahl, who declares it, contrary to Buxbaum's opinion, to be totally distinct from V. dioica. The plant resembles Sifymbrium rofulatum. Stem from the fruit, and the root, high, finely fratted, smooth, as well as every other part, leaflets; the outer pair of leaflets, of which are smaller, alternate, and more ovate: the innermost of which are smaller, alternate, and more thinly fratted; the outer feffile and opposite; the odd one an inch long, ovate or roundish, very blunt, obscurely ribbed; sometimes the top leaves are ternate only. Flowers in a dense, level-topped, nearly simple corymbs, remmbling those of V. officinalis. Bracteas linear, shorter than the flower. Stamens three. Style three-cleft. This appears, by the above description of Vahl, to be likewise related to V. Dioecoides. We have seen neither specimen nor figure.

20. V. capengii. Cape Valerian. Thunb. Prodr. 7. Willd. n. 5. Vahl n. 18.—"Leaves pinnate; leaflets ovate, toothed. Stem hairy at the joints."—Found by Thunberg at the Cape of Good Hope. The stem is said to be furrowed; smooth, except the joints. Corynbs forked.

22. V. decussata. Cross-branched Valerian. "Fl. Peruv. v. 1. 42. t. 70. f. b." Vahl n. 20.—"Leaves pinnate; leaflets lanceolate, finely toothed; hairy and downy beneath. Branches of the panicle forked and diarivated."—Found about hedges, and floty places, in Peru. Stem herbaceous, though somewhat climbing, three feet high, fratted, hairy, a little downy. Leaves on short flalks; leaflets gradually larger outwards, dinantly and minutely toothed; downy above; more densely so beneath. Panicles very large, with horizontal partial flower-flalks. Bracteas under each division linear. Corolla minute, white. Seed crowned with ten or twelve rays. Vahl.

The flowers grow in lateral, somewhat forked, spidik panicles. Corolla tubular, greenish-rose-coloured, with five equal spreading teeth. Stamens three. Seeds comprefsed, ovate, fratted, with a feathery crown. Loefling. We have never seen, or heard of, a specimen of this plant in Europe, Linnaeus having described it from Loefling's authority only.

24. V. fangiflorulub. Burnet-leaved Valerian. Caian. Ic. v. 5. 34. t. 456. Vahl n. 22.—"Leaves pinnate; leaflets ovate, toothed. Corynbs compound. Stem hairy at the joints.—Native of the Cordilleras of Chili, flowering in January. The stem is about a foot high, ascending, leafy. Radical leaves forked, of about six pair of small, roundish-
roundish-ovate leaflets, furnished with one or two broad blunt teeth at each side; the odd one much more elongated and narrower. Branches of the pinnate compound, corymbose. Seed-crown of ten feathery rays.

25. V. virgata. Many-twig'd Valerian. "Pl. Peruv. v. 1. 42. t. 66. f. b." Vahl n. 23.—Leaves pinnate; leaflets cloven or three-cleft, with linear segments. Branches of the corymb forked.—Native of precipices in Peru. Smooth, with the habit of Tagetes minuta. Stem rather shrubby, three feet high, much branched, square, fluted, scarcely hollow, obscurely downy; the branches upright and wand-like. Leaflets minute; some undivided; others with two, three, or four, linear, emarginate or entire, segments; shining on the upper side. Partial flower-heads forked, with opposite linear bracteoles. Flowers sessile in the forks. Seeds irised on one side, gibbous on the other. Vahl.

—Not very uncommon in flowy ground, on the alps of Switzerland, the Grisons, Germany, and the Pyrenees, flowering in July and August. The root is long, creeping, perennial, with a flight degree of the flavour belonging to this genus. Stem a foot high, more or less, ascending, leafy, unbranched. Radical leaves on long stalks, heart-shaped or spatulate, acute, smooth, an inch or two in length, with various broad, slender, wavy teeth; the rest more oblong and pointed, on short stalks. Flowers numerous, corymbose, small, pale flesh-coloured.

27. V. intermedia. Ambiguous Valerian. Vahl n. 25.—"Leaves simple, nearly entire; the lowermost oblong-heart-shaped; uppermost lanceolate; three pairs on the stem."—Brought from the Pyrenees by Mr. Hornemann. Akin to the last, though the leaves being not heart-shaped, nor toothed, as in that, but lanceolate and entire, induced Professor Vahl to reckon it distinct.

28. V. tripteris. Three-leaved Valerian. Linn. Sp. Pl. 45. Willd. n. 8. Vahl n. 26. Ait. n. 7. Jacq. Aul. t. 268. (V. alpina prima; Bauh. Prod. 86. V. alpina faxatilis minor, flore albo; Barcel. 1. t. 742. V. alpina minor, et minimia; Pluk. Phyt. t. 231. f. 7. 8.)—Leaves toothed; the radical ones heart-shaped, simple; those of the stem lanceolate, ovate-oblong; their lateral leaflets lanceolate. Found on the alps of Austria and Switzerland, intermixed with V. montana, but flowering a little earlier, and the flowers are more generally white. Nevertheless, these two species are so very nearly akin, that we could almost suspect them to be varieties of each other, and that Vahl's intermedia may belong to one and the same species.

29. V. villosa. Downy Valerian. Thunb. Jap. 32. t. 6. Willd. n. 18. Vahl n. 27.—Stamens four. Corolla equal. Leaves densely downy; the radical ones auricled; floral ones toothed.—Native of various places in Japan, flowering in September and October. The root appears to be perennial. Whole herb densely downy or hairy, a span high, unbranched. Leaves all toothed; the radical ones flaked, oval, near two inches long, with a pair of much smaller confluent auricles. Pinnate corymbose, forked. Flowers yellow. Wildmenow refers this species, like V. fibrica, to the Fedia, but Vahl makes it a Valeriana. Having seen no specimen, we are unable to form a decided opinion, the fruit not having been noticed by Thunberg, whose figure and description are our only authority.

30. V. pyreica. Heart-leaved Valerian. Linn. Sp. Pl. 46. Willd. n. 14. Vahl n. 28. Don. Herb. Brit. f. 477. Sm. Compend. ed. 2. 8. Engl. Bot. t. 1591. (V. maxima, caulis folio; Pluk. Phyt. t. 232. f. 1. V. canadensis; Rivin. Monop. Irr. t. 4.)—Stem-leaves heart-shaped, serrated, all flaked; the upper ones pinnate or ternate.—Native of the Pyrenees, and of Scotland; having been found by the late Mr. George Don, about ditches and walls at Blair-Adam, Kinross-shire, and subsequently near Glasgow and Edinburgh, flowering in June. Dr. Brown of Glasgow has also met with this plant in several woods of the south of Scotland, widely separated from each other. It is perennial, from three to five feet high, of a flout habit, and dark green hue, nearly smooth, pollissng the smell, probably the virtues, of V. officinalis, Discoreis, &c. Stem downy about the foot, as are the roots of the flower. Leaves large, with copious, unequal, tooth-like serratures; the radical ones, sometimes the others, simple; but for the most part the stem-leaves bear one or two pairs of small lanceolate leaflets on their stalks. Flowers rose-coloured, in a dense, large, compound, terminal corymb. Stamens three.

31. V. alliariesefolia. Garlick-mustard-leaved Valerian. Vahl n. 29. (V. orientalis, alliaries foio, flore albo; Tourn. Cor. 6. Buxb. Cent. 2. 19. t. 11.)—Leaves heart-shaped, unequally toothed, all simple; the upper ones sessile.—Gathered by Turnefort in Cappadocia. Distinguished from the last, with which Linneus confounded it, by being perfectly smooth, with thinner leaves, besides what is expressed in the specific definition. Vahl examined Turnefort's original specimen. The flowers are white.

32. V. hypaphisfolia. Dock-leaved Valerian. Vahl n. 30.—"Leaves heart-shaped-ovate, undivided, nearly entire; the upper ones sessile."—Gathered by Commenon, in the fraits of Magellan. Root perennial. Stem a foot or more in height, as thick as a quill. Leaves three inches long, gradually smaller upward, acute, entire, or sometimes slightly crenate, ribbed, obscurely veined, smooth, except the upper side of the ribs; those at the root, and lower part of the stem, stalked; upper pair sessile; lowest floral leaves linear, obtuse, fringed at the base. Flower-flasks corymbose; the axillary ones opposite, of few flowers; terminal ones three-forked, many-flowered. Stamens three. Vahl. We find no specimen of this species among the large communications of M. Thouin to the younger Linneus.

33. V. vonaefolia. Fleathy-leaved Valerian. Sm. Plant. 1. t. 52. Willd. n. 22. Vahl n. 31. (V. magellanica; Lamarck Illust. v. 1. 93.)—Leaves oval, toothed, fleshy, glaucescent; the radical ones on long stalks.—Gathered by Commenon, in the fraits of Magellan. Stem about a foot high, erect, simple, smooth. Leaves all, according to Commenon, thick, succulent and glaucous; radical ones obtuse, an inch or inch and half long, with broad unequal teeth; tapering at the base, into a footstalk twice or thrice their own length; stem-leaves about three pair, much smaller, nearly sessile. Flowers purple, nearly regular, triandrous, in small, dense, level-topped corymbs. Seed crowned with teeth, rather than with feathery down; so far at least as we can judge from our specimen. It is not impossible that this species may be a Fedia, as Wildenow makes it; though the seed, like that of Fedia (or Valeriana) Corncopias, resembles true Valerians. Indeed our vonaefolia and polyphylla appear to form, through V. Corncopias, the connecting links of these two genera.

—Native of the mountains of Italy and Dauphiny. The root is cylindrical, woody and perennial, branched at the top, and crowned with many tufts of oblong-lanceolate, or spatulate, falked leaves, more or less obtuse, of a much thicker texture than the leaf, an inch and half long. Stems solitary, two or three inches high, bearing near the middle a pair of combined smaller leaves, occasionally jagged or pinnaled at the base. Sometimes there is a similar pair lower down. The flowers are crowded into a round head, sometimes accompanied with two small corymbose branches just below, and subtended by two or four oblong entire bracteas, as well as intermixed with smaller ones, all slightly fringed. Stamens three. Seed flatted, with a feather crown. The herb is smooth in every part, except the bracteas, and very strongly scented.

40. V. celtica. Celtic Nard Valerian. Linn. Sp. Pl. 46. Wild. n. 10. Vahl n. 38. Ait. n. 9. Jacq. Coll. v. 1. 24. t. 1. (V. n. 209; Hall. Hist. v. 91. Nardus celtica; Ger. Em. 1079. Spica celtica; Camer. Epit. 14.)—Leaves oblong, obtuse, entire, rather fleshy, quite smooth. Flowers racemose; partial flanks capitatis.—Native of the Alps of Austria, Switzerland, &c. Root oblong, creeping, fleshy, with a very powerful and oppressive peppery smell. Herb of the nature of the falk, with fleshy, smooth, but always entire, leaves. Inflorescences widely different, so that these Species can never be confounded by those who have few in them in flower. The calyx of the present is about two inches long, lax; each branch, whether simple or forked, terminating in a little bracteated head, of three or four fleshy yellowish flowers, with three flammes. The seed has a feathery crown, and is sometimes covered with dense hairs.

35. V. Spica. Spikenard Indian Valerian. Vahl n. 33; ("V. jetamand; John in Ac. Bengh. (Astatic Reche.) v. 2. 405. v. 4. 433, with a figure."")—"Radical leaves heart-shaped, whole of the flem oblong."—Native of Bengal. The Rev. Dr. John supposes it the Spikenard of the ancients. The root is perennial, somewhat branched, covered with bristles in the upper part. Stem from fix to twelve inches high; its base entire, encompased with fibres. Leaves smooth; the two lowermost heart-shaped-oblong, waved, acute. Corymb forked. Vahl.

36. V. elongata. Long-clustered Valerian. Linn. Sp. Pl. 1664. Wild. n. 13. Vahl n. 54; Jacq. Enum. 203. t. 1. Ait. t. 219. (Nardo celtica simila alta, five Valeriana alpina minor; Linn. Ann. Acad. v. 1. 154.)—Radical leaves ovate, wavy; those of the flem sessile, somewhat heart-shaped, broadly toothed and cut. Panicle loose, elongated.—Native of the Auffrian mountain of Schneeberg. We have specimens also, gathered by Mr. Sieber, from Carinthia; and one found by Scopoli in Carniola. This is one of the rarest alpine plants, and appears never to have been seen by Vahl. It is perennial, flowering in June and July. Root long, slender, with numerous long fimples fibres. Stem from fix to five inches high, slender, leafy, smooth like the rest of the flem. Leaves from an inch to an inch and half long, molly ovate; the upper pair small, narrow, and jagged. Flowers small, pale yellow, with a tawny tinge, forming a lax, racemose, forked, compound panicle, about two inches long. We have not seen the crown of the seed, nor does any author describe it.

37. V. fujina. Dwarf Valerian. Linn. Mant. 27. Wild. n. 17. Vahl n. 35; Ard. Spec. f. 2. 13. t. 3. Wulf. in Jacq. Misc. v. 2. 114. t. 17. f. 2.—Leaves fimple, fpatulate, entire, fringed; the uppermost lanceolate.—Found about the boggy sandy margins of mountain rills, on the alpine heights of Austria, Carinthia, and the Tyrol, near the limits of perpetual snow. The creeping perennial roots throw out many trailing feyons, and are crowned with several dense tufts of falked, obovate, bright-green leaves, smooth on both sides, finely fringed with fhort hairs. Stems two or three inches high, more or less leafy, corymbose at the top. Bracteas long, lanceolate, acute, fringed. Flowers of a delicate rose-colour. Stamens occasionally four. Seed-crown long and feathery.

38. V. faxatilis. Rock Valerian. Linn. Sp. Pl. 46. Wild. n. 12. Vahl n. 6; Ait. n. 11. Jacq. Ait. t. 267. (V. fylverfolia alpina altera faxatilis; Clus. Hist. v. 2. 56. V. alpina angustifolia; Ger. Em. 1077.)—Leaves fimple, undivided; radical ones elliptical, three-ribbed, rather hairy, entire, or finely toothed; those of the flem linear. Corymb racemose.—Native of the alps of Styria, Italy, and Austria, but rarely in the latter country, as we are informed by professor Jacquin, jun. to whom we are indebted for specimens. The root is perennial, crowned with fibrous remains of old leaf-flalks. Stem a fpan high, slender, smooth. Radical leaves on long flalks, erect, an inch and half or two inches long, obtuse, almost perfectly entire, a little hairy occasionally; tapering at the base: those on the flem long and narrow, falked, sometimes a little jagged, scarcely more than one pair, about half way up the flem, except the till narrower and smaller bracteas at the base of the inflorfection. Flowers few, white, corymbose, each little tuft supported by a very long slender flalk. Jacquin affirms them to be dioecious. He gives no account of the structure of the seed-crown, nor do we find that part anywhere described.

—Native of the mountains of Italy and Dauphiny. The root is cylindrical, woody and perennial, branched at the top, and crowned with many tufts of oblong-lanceolate, or spatulate, falked leaves, more or less obtuse, of a much thicker texture than the leaf, an inch and half long. Stems solitary, two or three inches high, bearing near the middle a pair of combined smaller leaves, occasionally jagged or pinnaled at the base. Sometimes there is a similar pair lower down. The flowers are crowded into a round head, sometimes accompanied with two small corymbose branches just below, and subtended by two or four oblong entire bracteas, as well as intermixed with smaller ones, all slightly fringed. Stamens three. Seed flatted, with a feather crown. The herb is smooth in every part, except the bracteas, and very strongly scented.

40. V. celtica. Celtic Nard Valerian. Linn. Sp. Pl. 46. Wild. n. 10. Vahl n. 38. Ait. n. 9. Jacq. Coll. v. 1. 24. t. 1. (V. n. 209; Hall. Hist. v. 91. Nardus celtica; Ger. Em. 1079. Spica celtica; Camer. Epit. 14.)—Leaves oblong, obtuse, entire, rather fleshy, quite smooth. Flowers racemose; partial flanks capitatis.—Native of the Alps of Austria, Switzerland, &c. Root oblong, creeping, fleshy, with a very powerful and oppressive peppery smell. Herb of the nature of the falk, with fleshy, smooth, but always entire, leaves. Inflorescences widely different, so that these Species can never be confounded by those who have few in them in flower. The calyx of the present is about two inches long, lax; each branch, whether simple or forked, terminating in a little bracteated head, of three or four fleshy yellowish flowers, with three flammes. The seed has a feathery crown, and is sometimes covered with dense hairs.

4 B 2
of Peru. The habit of this species is like Polygonum Peru-
caria. Stems several, much branched, with a grey bark; 
branches ascending, straight, jointed, somewhat sheathed, 
hollow; marked when young with two downy lines, alter-
nately crossing each other, of a dark tawny colour, frilated. 
Leaves tapering and fringed at the base, but otherwise 
smooth. Common flower-flalk elongated; partial ones op-
posite, three-cleft, with a pair of small combined leaves 
at each side. Bracteas lanceolate Obtuse. Calyx bordered. 
v. 1. 39. t. 66. f. a." Vahl n. 42. "Leaves lanceo-
late, entire, revolute. Corymbs racemose."—Native of 
the colder regions of Peru. This has the aspects of Plantago 
albicra. Root branched. Stem solitary, occasionally two 
or three, erect, a foot high, frilated, bearing two linear 
leaves about the middle. Radical leaves very numerous, six 
inches long, unequal, erect. Corymbs opposite, in the upper 
part of the stem, with from three to five partial spikes. 
Flowers sessile, in a head, with obovate bracteas intermixed. 
v. 1. 39. t. 66. f. a." Vahl n. 42. "Hairy. Leaves lanceo-
late, entire, revolute. Corymbs racemose."—Native of 
the colder regions of Peru. This has the aspects of Plantago 
albicra. Root branched. Stem solitary, occasionally two 
or three, erect, a foot high, frilated, bearing two linear 
leaves about the middle. Radical leaves very numerous, six 
inches long, unequal, erect. Corymbs opposite, in the upper 
part of the stem, with from three to five partial spikes. 
Flowers sessile, in a head, with obovate bracteas intermixed. 
v. 1. 40. t. 68. f. a." Vahl n. 43. "Leaves wedge-shaped-
lanceolate, minutely toothed, fringed. Flowers in whorled 
spike."—Native of cold situations, on the lofty mountains 
of Peru. Root tapering, perennial, divided in its lower 
part. Stem nearly a foot high, frilated, downy with deci-
duous hairs; naked below; leafy above. Radical leaves im-
bricated, five or eight inches long, channelled, tapering at 
the base; purplish externally; the floral ones three or four, 
lanceolate, smooth on both sides, finely toothed and fringed, 
as well as the radical ones. Flowers sessile, in crowded 
whorls, the lowest whorl only being dilant from the rest. 
Bracteas short, wedge-shaped. Seed oblong, crowned with 
five scales. Vahl. It is manifest that this species and the 
three following are as much entitled to be ranked with Fedia 
as many others. 
40. t. 68. f. c." Vahl n. 44. "Leaves wedge-shaped-lan-
colate, terraced towards the extremity. Flowers in whorled 
spike."—Native of cold situations in Peru. Root peren-
nial, thick. Herb tufted, smooth. Stems several, frilated, 
nearly leafless; the middle one fix inches high, leafy under 
the flowers. Radical leaves numerous; floral ones frilated 
at the extremity. Spike terminal, five or six inches long. 
Flowers sessile, in many-flowered whorls, of which the 
lower ones are dilant, the upper crowded. Bracteas wedge-
haped, membranous between the flowers. Seed oblong, 
crowned with five scales. Vahl. 
t. 65. f. c." Vahl n. 45. "Stem none. Leaves lanceo-
late, aggregate, imbricated, spreading, the upper ones gra-
dually smaller."—Native of the mountains of Peru. Root 
spindle-shaped, perennial. Radical leaves extremely nu-
merous, spreading in the form of a rofe, an inch and half long, 
enure, with a cartilaginous edge, coriaceous, rigid, without 
arb or veins; minutely dotted on both sides; shining on the 
upper surface; fringed towards the base; terminating in a 
rather pungent point; lying over one another in an imbric-
ated manner, the innermost being gradually smaller. 
Flower-flalks, if any, very short, in the centre of the leaves, 
compressed, white, tapering at the base. Flowers with a 
general, as well as partial, involucrum, each of one leaf, 
heathing, divided. Calys a very minute border. Stigma 
v. 1. 39. t. 65. f. a." Vahl n. 46. "Stem none. Leaves 
linear-awl-shaped, aggregate, feffile, imbricated, spreading; 
the outermost very long.—Native of the mountains of Peru. 
Root perenniial, spindle-shaped. Radical leaves numerous, 
unequal, spreading in the manner of a fir, entire, veins, 
smooth and flinching, with a rather rigid point; dilated 
and membranous at the base; dilated in their lower part. In 
other respects this species agrees with the latl, both being 
widely different in habitat from the rest of their genus. 
Vahl. 
Valeriana, in Gardening, contains plants of the hardy, 
herbaceous, perennial kind, among which the species cultivated 
are, the common or broad-leaved red valerian (V. rubra); 
the narrow-leaved red valerian (V. angustifolia); the 
cut-leaved valerian (V. calcitrapa); the garden or white 
Alfian valerian (V. phu); the three-leaved valerian (V. 
tripetra); the mountain valerian (V. montana); the Celtic 
valerian (V. celtica); the tuberous-rooted valerian (V. tu-
berofa); the Pyrenean valerian (V. pyrenaica); the official 
valerian (V. officinalis); and the common corn-fallad, 
or lamb's lettuce (V. oitioria). 
The first fort differs in some degree in the colour of its 
flowers; they being in some plants of a deep red, in others of 
a pale red, a bright red, and there are others which have white 
flowers. The second fort has bright red flowers, smaller than 
thofe of the former. The third is an annual plant, which has 
the flowers shaped like those of the fourth fort, but smaller, 
and tinged with flesh-colour at the top: it and varies with the 
lower leaves pinnaflid. The fourth fort has the branches 
terminated by bunches of small white flowers, the colour of 
which is very agreeable. The fifth has the flowers numer-
ous, white, and in loose bunches. In the sixth fort the stem 
is upright, simple, a foot or eighteen inches high, with the 
flowers of a whitish or purplish colour, in a bunch. The 
seventh fort has the item flender, simple, and terminated by 
a few small whitish flowers in a bunch. The eighth fort is 
easily distinguished by its tuberous roots; and there is a 
variety with the roots in the form of an olive. The ninth 
fort has the item and branches terminated by umbels of pale 
fiish-coloured flowers, with very short spurs. The tenth 
fort has the flalks two feet high, all of which and the 
branches are terminated with umbellate clusters of flowers 
tinged with purple. The laft fort has the flowers very 
small, of a pale blueish colour, and collected into a clofe 
little bunch. It is used in fallads in the early spring and 
winter, under the name of corn-fallad, or lamb's lettuce. 
There is a variety which is smaller, with jagged leaves: 
the fizes of the leaves also differ much, being in some nar-
row, and in others broad, and likewise in the flape; but they 
are all used indifferently as fallad herbs while young. 
Method of Culture.—The two first forts may be increased 
by parting the roots, and planting them out in the autumn 
or spring leafon, where they are to grow. 
They may also be raised from seed fown at the fame times, 
in the situations where the plants are to grow. The third 
may likewise be raised from seeds, by bowing them as above, 
without any trouble. The fourth may be increased by 
parting the roots, and planting them out in the autumn, on 
fresh ground where they are to grow. The fifth may be 
raised
raised in the same way, being allowed good room, as it spreads much. The three following doses are more difficult to prefer, requiring a strong foil and cold exposure. The ninth dose may be raised from seeds sown in a moist shady border soon after they are ripe, managing the plants as in the first dose. The tenth dose, as well as the fourth, are mostly cultivated as medicinal plants, for which purpose they should be disposed in beds with others of the same kind. They may be raised by parting the roots, as well as by the seeds. The last dose, when cultivated for the purpose of a fallow, should be sown in the latter end of summer, or beginning of autumn, in an open place, where it is to grow; the plants being afterwards thinned out by hoeing, and kept clean from weeds; when they will be fit for use very early in the spring while quite young.

All the doses, except the last, may be introduced in the borders, for the purpose of variety, and most of them continue many years. They may all be had at the proper planting feasons, as the autumn, winter, and spring, in the public nurseries gardens.

The last is used as an early spring fallow-herb.

VALERIANA, in the Materia Medica. There are various kinds of valerian; but those chiefly in medical ufe are the large garden valerian, valeriana officinalis; called by Dioscorides, valerian of Plu, folio abstrati; and the valeriana fuchstata, or great wild valerian.

The former is an ingredient in Venice treacle; its chief ufe is in disorders of the nerves; in which respect, however, it is held inferior to the latter.

The wild valerian, valeriana officinalis of Linnaeus, or valeriana fuchstata major montana of Bauhin, is perennial, and grows wild in dry mountainous places. The root consists of tough twigs, with numerous smaller threads, matted together, issuing from one head, of a dull-brown colour approaching to olive. Cows eat the leaves, and cats are very fond of the roots. Rats are also said to be equally fond of these roots, and rat-catchers employ them to draw the rats together. Another species, or variety, of wild valerian is met with in moor watery grounds, distinguitahable by the leaves being broader, and of a deep glossy-green colour. Both sorts have been used indiscriminately; but the mountain sort is much the moft efficacious, and is, therefore, expressly ordered for the officinal species by the London College.

The mountain valerian, or narrow-leaved variety of this species, not exceeding two feet in height, and affecting dry heaths and high pastures, is chiefly in repute: its root manifests stronger fefible qualities, and poses itself more medicinal power: its smell is strong, resembling that of a mixture of aromatics with fetids, and it has an unpleafant, warm, bitterish, labradic taste: the strength of the smell and taste is the only certain tell of its genuineness and goodnefs. It is a medicine of great efficacy against obftinate hemorhan, hypertenfion and the different kinds of nervous disorders, and is commonly confidered as one of the principal antifeptic medicines. Dioscorides and Galen mention it as an aromatic and diuretic. Columna reports, that he was cured by it of an invertebrate epilepsy after many other medicines had been used in vain.

M. Marchant, in the Memoirs of the Academy of Sciences, has confirmed this virtue, by many inftances within his own knowledge: and what is very remarkable is, that in the two obervations he enlarges most upon, the patients, on taking it, voided great quantities of worms. His cuflom was always to purge before he administered it.

On more extensive trials it has been found, in some epileptic cafes, to effect a cure, in several to abate the violence or frequency of the fits, and in many to prove altogether ineffectual: oftentimes it either purges or operates by sweat or by urine, or brings away worms, before it prevents a fit. The dose of the root in powder is from a drachm to two, which may be repeated, if the flomach will bear it, two or three times a day. Dr. Withering says, that in habitual colliquiments it is an excellent medicine; and frequently loosens the bowels when other stronger purgatives have been tried in vain. A remarkable influence of its efficacy in a catalepsy is given by Mr. Musgrave (on the vis vitae, &c.) doses of half an ounce of the powder were exhibited twice a day, and a less quantity was found ineffective.

The advantages said to be derived from this root in epilepsy, caufed it to be tried in several other complaints denominated nervous, particularly those produced by increased mobility and irritability of the nervous system, in which it has been found highly serviceable. Bergius states its virtue to be antifeptic, diuretic, emmenagogue, diuretic, and anehimetic. And under the head of its ufe, he enumerates epilepsy, convulsions, hysteria, hemorhan, and vitus herbud. Fordyce commends it in this last difpance. Wynt, who joined it with manna, experienced its utility in epilepsy. M. Morgan found it ufeful in resolving glandular or flumous tumours. Dr. Cullen allows, that its antifeptic activities are well eftablifhed, and he thinks it should be given in larger doses than thofe that are commonly ufed. Accordingly he has found it frequently ufeful in epileptic, hysteric, and other fapmodic affections. It is faid, however, that it has been sometimes given in cafes of epilepsy, to the extent of two ounces a day without effect; and Dr. Woodville obferves, that his own experience warrants him in faying, that it seldom has been found to answer the expectation of the preffurer.

The powdered root, infufed in water, or digifte in redlifted spirit, impragnates both menilura strongly with its uell and taste, and tingies the former of a dark brown, and the latter of a brownish-red colour. Water diftilled from it smells confiderably of the root, but no effential oil separates: the extract obtained by infufitating the watery infufion, which is about one-fourth the weight of the root, has a pretty strong taste, disagreeably sweet, and fomewhat bitterish: the spirituous extract, which is about one-eighth the weight of the root, is fels disagreeable, and more perfectly resembles the root itself.

Tinctures of it are prepared in the offops, by digifteg four ounces of the powdered valerian in a quart of proofsprit, in the fame quantity of the volatile aromatic spirit, or of the dulcified spirit of fal ammoniac. The root in fubfance, however, is generally found to be more effeetual than any preparation of it: and its flavour may be better covered with mace, Lewis and Woodville.

VALERIANELLA, in Botany, the diminutive of VA- LE-RIANA, the article and Fera.

VALERIANO BOIZANI, a Pen, in Biographies, was born at Belluno, in 1477, in such a low condition, that he had no opportunity of acquiring the fift elements of literature till he attained the age of fifteen years. After having been reduced to the neceflity of entering into the service of a noble person at Venice for support, he devoted himself to study under eminent teachers; and agreeably to the practice of the age in which he lived, changed his baptismal name of Gianpietro for Piero. In his 23d year he engaged in the study of philosophy at Padua, and palled three years in a retreat at mount Olivet, in the Veronese. Upon his return to his native place, he found it possessed by the imperial army.
army in 1599, so that he was obliged to make his escape to Rome. Here he fortunately became known to cardinal Giovanni de Medici, by whom, when pope Leo X., he was honourably provided for in his court. At the termination of this pontificate, he paifed some time at Naples; but upon the accession of Clement VII. he returned to Rome, and was promoted to the chair of eloquence, with the title of prothonotary and private chamberlain, to which was added a canonicity, and some other benefice in Belluno. Having employed himself in Latin poetry, he relinquished the composition of elegies and amatory pieces, by which he had acquired reputation, upon taking holy orders. To him Leo X. committed the instruction of his two nephews, Ippolito and Alessandro de Medici, and he accompanied them to Florence, where he resided in the year 1527, when they were expelled from that city. After sharing their misfortunes, he attended them to Florence in 1530. Upon their death, he withdrew from Belluno, and then to Padua, where he elapsed his life in 1558, at the age of eighty-one years.

The work by which he is principally known, is his treatise "De Inflencitate Literarum," first printed in Venice in 1620, and often reprinted. Another of his publications was intitled "Hieroglyphica, sive de facris Ægyptiorum aliarumque Gentium litteris Commentariorum, Lib. LVIII.;" Basel, 1566. Some of his other performances were, "De Sul- minum Significationibus," Rome, 1517; "Pro Sacrodo- tun Barbus defenso," 1531; "Cagnifikations Virgiliane lectionis," first printed in R. Stephens's edition of Virgil, Paris, 1532, and since annexed to various other editions; and "Antiquitates Bellunenses." He also published two volumes of his Latin poems. Moreri. Tirabofchi. Gen. Biog.

VALERIUS FLACCUS. See Flaccus.

Valerius Maximus, a writer whose history is little known. The work which has been ascribed to him, and entitled "De Dictis et Factis Memorabilibus Antiquorum, Lib. IX.;" appears to have been written in the reign of Tiberius, probably after the death of Sejanus, and dedicated with high eulogy to Tiberius. It is cited by Pliny the elder, Plutarch, and A. Cellius; and it was much read and quoted at the revival of literature in Europe. One of the early editions, which were numerous, is supposed to have been prior to 1460; of the later editions, the most esteemed are the "Variate," Lugd.-Bat. 1670; the "Delphin," Paris, 1679; "Torreini," Lugd.-Bat. 1726; and "Kappii," Lipt. 1752.

Valerius Poplicola, Publius, an eminent Roman, and one of the founders of the republican government, distin- guished by his simplicity, eloquence, and liberality. In a contention about the confiscate, at the expulsion of the Tar- quinian family, he was elected to supply the place of Colla- tinus, who was removed from office, and lived on terms of the utmost harmony with his colleague, the celebrated Junius Brutus. In the subsequent battle with the allies of Tar- quin, in which Brutus was slain, Valerius gained a victory, for which he obtained a triumph, B.C. 507. Destroying the election of a new confid, and having built a house on the Palatine hill, that overlooked the forum, he excited the suspicion of the people; but as soon as he understood the ground of their jealousy, he ordered the house to be levelled in the night, and gave orders for supplying the vacancy in the confis- cutate. The father of Lucretia was chosen, but by his death soon after his election, Valerius was again the sole chief magistrade. In the exercise of his office he enacted several laws, abridging the confis cutary authority, and meliorating the condition of the people; and hence obtained the name of Poplicola, or the people's friend. As a proof of his inte- grity and disinterestedness, he removed the public treasury from his own house to the temple of Saturn, thus committing it to the charge of two senators appointed by the people. Upon an election of confis, his popularity occasioned his being chosen a second time. When, in the following year, Pofrena, king of Clusium, in Tuscany, attempted the re- formation of Tarquin, and by an arm which he marched to Rome reduced the city to great difficulties, Poplicola agreed to resign some of their conquests as the price of peace; and his own daughter Valeria was one of the hof- tages. In a war with the Sabines, Poplicola was nominated for the fourth time a confis; and by his military skill ob- tained a complete victory over the enemy, and recovered the town of Fidenza. For this success he obtained a triumph, and soon after died, having established the character of one of the greatest men and most virtuous citizens of Rome. Although he had occupied many lucrative posts, he did not amass money sufficient to defray the expense of his funeral, which was paid by the public; and in honour of his memory, as in the case of Brutus, the matrons of Rome wore mourn- ing for a year. His principles were transmitted to his fam- ily from one generation to another, so that the Valerii were afores of the rights of the people. Livy. Dionyfus Hal. Anc. Up. Hift. Gen. Biog.

Valerius, Lucas, an eminent mathematician, acquired great celebrity at Rome as professor of geometry, and was honoured by Galileo with the appellation of the Archimedes of his time. He died in this city in 1618. He prosecuted the discovery of the centres of gravity of solids, and shewed how to determine them in all the conoids and spheroids, and their respective segments formed by planes parallel to the bases. The result of his investigation was published in 1604, in a work entitled "De Centro Gravitatis Solidorum." He also propounded a quadrature of the parabola different from that of Archimedes. His method was published in 1666, and an- nexed to the fore-mentioned treatise. Montucla.

VALENS REALES, or Royal Bonds, in Commodies, are a kind of paper currency, which was first issued by the Spanish government in the year 1800, for the following sums:

- 600 dollars = 9035 reals 10 maravedis vellon.
- 300 ditto = 4517 ditto 22 ditto.
- 150 ditto = 2258 ditto 28 ditto.

These bonds are transferrable only by indorsement; they bear an interest of 4 per cent. per annum, and were made a legal tender for their full amount, with any interetl that might be due upon them; but, from various causes, they have experienced a considerable depreciation. Kelly's Un. Cambif.

VALESIANS, VALESIANIS, in Ecclesiastical History, in- cident sectories, so called from one Valerius, a person un- known to Epiphanius, who, however, makes mention of this sect, Hr. 58, though he owns he knew but very little of them; only this, that they admitted none into their society but eunuchs; at last, if any were admitted before castration, they obliged them not to eat any meat till the operation was performed. For then, being no longer subject to the motions of the flesh, they allowed them to eat any kind of meats. Whilton says of them, that they sprang up about the year 240, and that they rejected the law and the prophets.

VALESIUS, in Biography. See Valois.

VALESTR, or VALEST, a French term, anciently written warkt.
VAL

In France, valet is a common name for all domestic servants employed in the lower and more servile offices; including what we call grooms, footmen, coachmen, bailiffs, &c. But the word is not used among us in this sense, nor any other than in the phrase valet de chambre; which is a servant, whose office is to dress and undress his master, to look to his bed-chamber, wait on him at table, &c. the name with what we otherwise call his gentleman.

In the History of Lewis XII. by Seifel, we always find valet de chambre du roi, valet de la gard-robe, &c. But valet, like knave, and divers other words, is now degenerated into a term of reproach.

Vallet, valeti, valetel, valet, and valet, Camden observes, were accidentally used at our court for a gentleman of the privy-chamber.

Selden, in his Titles, relates, that valets anciently signified young gentlemen, and heirs of great estate and quality; especially such as were to be knighted.

In the accounts of the Inner Temple, valet is used for a bencher's clerk, or servant. The butlers of the house still call them valets.

Vallet, in the Menga, a flick armed at one end with a blunted point of iron, to prick and aid a leaping horse.

Formerly, a valet was called aiguillon, i.e. goad, and some of them had four-rows upon them, only the points beaten down; and when a horse was first begun round a pillar, without a rider, they were to prick his flanks with the valet, to make him know the furr, and obey it, without refilling. At present the valet is not used for that purpose, and the name of goad is suppressed, as being only proper for oxen.

VALETTA, or CITTA NUOVA, in Geography, a city of Malta, and capital of the island, which, in the year 1565, was built by the grand-master Frederic John de Valetta, on a hill, in form like a neck of land extending itself into the sea, and was called by his name. Its walls are of large square stones, dug out of the rock, and planted with several batteries. On the point towards the sea flanks the castle of St. Elmo, a fortres which defends both the harbours; one of which, called Marfa Mafciotto, lies at the entrance from the sea to the right of the town, and incloses a small island, on which stands both a fort and a lighthouse. The other harbour, on the left side, is simply called Marfa, or the Great Harbour, being the largest, safest, and most commodious in this island, and having some bays. Its entrance, besides the castle of St. Elmo, is guarded by Fort Ricasoli, which flanks on the Punta del Orso, to the left. The town of Valetta lies on its right, and on its left the towns Il Borgo, or Vittoria, and Senglea. In Valetta is a handsome palace, where the grand-master resides, and before it a spacious area for exercises. Each of the seven nations, or tongues of this order, has its peculiar hall. The principal church is dedicated to St. John the Baptist. The Jesuits had a college here; besides which are several convents and nunneries, a large hospital, and a building where Turkish slaves are kept. The number of the inhabitants is computed to be about 2000. See MALTA.

VALETTE, LA, a town of France, in the department of the Iere; 15 miles S.S.E. of Grember—Allo, a town of France, in the department of the Charente; 12 miles N. of Angoulême.—Allo, a fort of France, in the department of the Var, near Toulon.

VALETUDINARIES, VALETUDINARIES, a term sometimes used, by the writers on medicine, for a person of a weak, sickly constitution, who is very frequently out of order, &c.

Dr. Cheyne, by all means, directs the weakly, the fluxious, the febrile, and the valetudinary, to a low, spare regimen.

VALEUR des Notes, Fr.; Value of Notes, in Musick. Beside the position of the notes on the staff, which fix the tone with respect to gravity and acuteness, they have all some peculiarity of figure, which marks their duration as to time, or comparative value as to length. In the ancient primitive time-table, in which all the notes are black or full, except the femibreve and minims, which are white and open, the shortest notes then in use are the longest now, and all that are open. The breve, indeed, equal to two femibreves, is still to be found in church-music of some antiquity, known by the titles alla breve, or a capella; but in all modern music, the femibreve is placed at the head of the other characters for time; and that note, divided into its aliquot parts, furnishes all the fractions in the most rapid compositions.

The dual measure, or common time, is governed by even numbers; as 2 minims, 4 crochets, 8 quavers, 16 semiquavers, 32 demisemiquavers, all which only amount to a femibreve.

Triple time, or ternary measure, is governed by the number 3; as 3 minims, 6 crochets, 12 quavers. In these numbers, the upper figure tells us how many notes there are in each bar, and the under, of what kind in the time-table; as 3 implies 3 minims, 6 three crochets, 12 three quavers.

One-third is added to the value of a note by a point or dot: as a femibreve equal to two minims, by a point is equal to three; a minim equal to two crochets, the point makes equal to three, &c. See Musick CHARACTERS, TIME, and Plate Time-table.

It was to John de Muris, who flourished about the year 1550, that the characters for time in music were long ascribed; but on examining and collating MSS. in the several great libraries of Europe, it has been clearly proved that it was not John de Muris who invented these characters, as he himself owns in one of his tracts, but Magister Franco of Coign, author of a treatise “De Musica Mensurabilis,” written in the eleventh century, long before De Muris was born; in which form the names of the notes is given, and their relative value explained.

This very scarce treatise is preserved in the Bodleian library, 842, f. 49. See FRANCO and De MURIS.

VALEY ISLAND, in Geography, a small island in the North Sea, separated by a strait called Valet Sound, from the fourth-wealth coast of the island of Shetland. N. lat. 60° 15'. W. long. 1° 58'.

VALFROIQUES, a town of France, in the department of the Vosges; 6 miles S. of Mirecourt.

VALGI. When the legs were deformed to such a manner that the feet were twisted outwards, the persons thus disfigured were termed VALGI; while others, who were deformed by an inclination of their toes inwards, received the appellation of VARI.

VALGOM, in Geography, a town of the island of Ceylon; 6 miles N. of Candy.

VALGORGE, a town of France, in the department of the Ardèche; 9 miles N.W. of Largentière.

VALGRANA, a town of France, in the department of the Stresa; 9 miles W. of Com.

VALHERMONA, a town of Portugal, in the province of Estremadura; 9 miles N.E. of Lesta.—Allo, a town on the north-west of the island of Goa.—Allo, a town on Spatia, in New Calde; 12 miles E.S.E. of Guadaljara.

VALI, in the mythological romances of the Hindoos, is a name given to a monkey, forgotten by their god Indra,
on a damsel of the semi-celestial tribe, called Upfarra. We may just notice, that this warlike monkey was killed by the great Rama, the hero of the extraordinary poem Ramayana.

VALIAM, in Geography, a small Ruffian island, in lake Ladoga; 92 miles N. of Peterburg.

VALIANO, a town of Etruria; 10 miles S.S.W. of Cortona.

VALID, a term applied to acts, transactions, expeditions, &c. which are clothed in all the formalities requisite to their being put into execution, and to their being admitted to a court of justice.

A contract by a minor is not valid, or is invalid: a marriage is not valid, unless performed with the solemnities enjoined.

VALIERO, Aostino, in Biography, a celebrated prelate of the church of Rome and a voluminous writer, was born of a noble family at Venice in 1531. Having studied both at Venice and Padua, with a view to the ecclesiastical profession, he graduated both in theology and canon law. In 1558, having previously been employed in several public offices, he became professed of moral philosophy at Venice, which post he occupied till the year 1565, when he was elected successor to his uncle as bishop of Verona, and he prefided over that city for forty-one years. In 1583 he was created a cardinal by Gregory XIII. Through the whole of his life, which terminated at Rome in 1606, in the 75th year of his age, he distinguished himself as the patron and promoter of literature, as well as by his zeal, charity, and munificence. The catalogue of his writings includes one hundred and twenty-eight. Of those that were printed, many being in MS., the most important are, "De Acylorum Disciplina," "De Rhetorica Ecclesiastica," "Epitoma Episcopi formà," "Cardinalis, sive de Optima Cardinale formà," "De recta philosophandi ratione," "De Cautione adhibenda in eandem libris," That his sentiments were liberal for the time in which he lived, appears from his treatise designed to prove that comets are not preages of calamities, and from another against the barbarism of the scholastics. He also wrote on the order and connection of the sciences and arts, and a large work on the Venetian history. Moreri. Tiraboschi.

VALIGA, a name given by some medical writers to an infusion or tincture of jalap in spirit of wine, or spirit of citron, with the addition of a little saffron.

VALIMONT, in Geography, a town of France, in the department of the Mofelle; 8 miles N.W. of Morhange.

VALINCOURT, John-Baptist du Trousset de, in Biography, was born of a noble family at St. Quintin, in Picardy, in 1653, educated at the Jesuits' college in Paris, and distinguished himself as a man of letters. In 1685 he was appointed, by the count of Touloue, admiral of France, his secretary-general, and afterwards secretary of the marine; but through life he cultivated polite literature, and became a member of the French Academy in the room of Racine, an honorary member of that of Sciences, and an advocate of the Academia della Crusca. He succeeded Racine as joint-historiographer with Boileau; but his labours on the reign of Louis XIV. were confounded with his library in 1725, a loss which he bore with philosophical composure, observing to one of his confiding friends, "I should little have profited by my books, if I had not learned how to lose them." He was an active promoter of literature and a protector of learned men, who had always free access to his house; and his character was distinguished by probity, sincerity, and good sense. He was inuch occupied, that his writings are few; they conflit of a critique on the celebrated novel of "The Princes of Cleves," "A Life of Francis Duke of Guise, furnamed Le Balafre," "Critical Observations on the Edipus of Sophocles," and a few poems. Such was his regard for religion, that towards the close of life, he held several conferences with ecclesiastics, for the purpose of terminating the divisions of the church with respect to the bull Unigenitus. He died at Paris, generally esteemed, in 1730, aged seventy-five years. Moreri.

VALINSAY, in Geography, a town on the W. coast of Luson. N. lat. 16° 18'. E. long. 120° 8'.

VALIODO, a town of Hindoostan; 15 miles E.N.E. of Travancore.

VALJova, a town of European Turkey, in the province of Servia; 50 miles N. of Jenibafar.

VALL, in Geography, a town of Sweden, in Warmeland; 28 miles E.S.E. of Carlladt.

VALLA, Giorgio, in Biography, a native of Placentia, and professor of polite literature in the university of Pavia in 1471 and 1476, from which he removed to the chair of eloquence at Venice in 1486. As he was one morning preparing to go to his school, where he explained Cicero's Tusculan Questions, and held daily disputations on the immortality of the soul, he died suddenly at the close of the 15th century. He was the author of many works, which are for the most part collections and transcripts from ancient writers, and translations from Greek authors, useful in that age, but not distinguished by judgment or accuracy. Bayle.

Valla, Lorenzo, was probably a relation of the preceding Valla, and born at Rome, as it has been said, in the year 1415; but as Tiraboschi says, before the year 1406. He was educated in his native city, and continued there till his twenty-fourth year. Having visited Placentia to take possession of the inheritance bequeathed to him by his relations, he settled at Pavia as professor of eloquence in the university. Here he was chargeable with some impieties of misconduct, so that he changed his abode several times, till he became attached to Alphonso, king of Naples, in which city he resided for some time; but in 1453, on the return of pope Eugenius to Rome, he settled in that city. Investigating the pretended donation of Constantin to the holy See, which he discredited, and reflecting on the characters of several popes, he incurred the displeasure of Eugenius, and found it necessary to withdraw first to Offlia, then to Naples, and finally to Barcelona. From hence he addressed an apology to the pope, and a defence of his writings on moral philosophy and dialectics, without any reference to Constantin's donation. He afterwards returned to Naples under the protection of Alphonso, and there opened a school of eloquence, to which many scholars referred; but notwithstanding his popularity as a teacher, he was accused and brought into danger on account of the freedom with which
which he maintained his peculiar opinions. Of these, we may mention his rejection of the letter of Christ to Abgarus as a fiction, and his repudiation of a celebrated preacher for affronting that each article in the apostles' creed was com-
posed by one of them separately. For the latter of these offences he was brought before the Inquisition, and owed his escape to the intercession of Alphonso, after a private flagellation in the cloister of monks. At length he was in-
vited to Rome by pope Nicholas V., who was distinguished by his patronage of literature; and in this metropolis he opened a school of eloquence, A.D. 1450. Here he entered into a dispute with George of Trebifond, secretary to the pope, on the respective merits of Cicero and Quintilian, to the latter of whom he gave a decided preference. His next conflict was with Poggio Bracciolini, who attacked him in five inquitives, to which Valla opposed as many antidotes, or dialogues, against Poggio. The manner in which this literary conflict was prosecuted was disgraceful to both par-
ties, and has been severely cenured by Tiraboschi. Although Valla was much occupied with disputes of this kind, he pursued his studies, and by order of Nicholas V. under-
took a version of the Greek of Thucydides into Latin, for which he received from the pope a recompense of 500 gold crowns, a canonry of St. John Lateran, and the place of apostolic scribe. For these favours on the part of the pope, Valla is charged with ingratitude. In the latter years of his life he visited King Alphonso at Naples, who exhorted him to translate Herodotus, but his death prevented his finishing the proposed version; however, for the part which he completed he was liberally rewarded. This translation was concluded by another person, and dedicated to Pius II. Valla's death oc-
curred in Auguli, 1457. The character of Valla is thus sketched by one of his biographers. He was "a man con-
sidered of his talents and acquirements, intolerant of other men's opinions, and free in his own, arrogant and contentious. His conduct was probably far from correct, though his enemies may have brought false or exaggerated charges against him. His philosophy was professedly Epicurean, placing the highest good in pleasure, which, however, he might explain in the least obnoxious sense. He was never married, but he confided in one of his answerers to Poggio, that he took a young woman to live with him, by whom he had three children, and whose fidelity to himself he extols, adding, that he hoped to procure for her a husband; but concubinage was at that time very common among the felicitors attached to the court of Rome in the capacity of a secret writer. He has al-
ways held a high rank, which he merited by unwarried application, and an enlarged course of study, comprehending history, criticism, dialectics, moral philosophy, and theology. That in the latter his notions were liberal, may be conjectured from some of the circumstances above related, and also from his notes on the New Testament, in which he was one of the first to consider the sense as a critic rather than as a divine, whence he was led to make many correc-
tions in the received translations. He is however said to have been but moderately versed in the Greek language, and Huet speaks very disparagingly of his versions of Thu-
cydides, Herodotus, and Homer's Iliad. Of his numerous writings, his "Elegante Latiniti Sermonis," containing the grammar of that tongue, and rules for composing in it, has been the most generally esteemed, and still retains its reputa-
tion: his own style, however, was defective. Point of
VALLABREGUES, in Geography, a town of France, Vol. XXXVI.
VALLADOLID, in the department of the Mouths of the Rhone; 3 miles N. of Tarazona.
VALLADOLID, a town of Spain, in the province of Leon, on a small river called Efequa, near the Pisuerga; the fee of a bishop, and an university, founded in the year 1346. Several of the churches of Valladolid, those espe-
cially of the Dominicans and of San Benito, are elegant, agreeably to the Spanish taste, that is handloose, and full of altars richly gilt. Valladolid is not wholly without ma-
ufactures; some stuffs and coarse cloths are made there
from the wool of the sheep which are kept in the neighbour-
hood. There are also gold and silver-smiths; and one street is entirely inhabited by jewellers: this is very lively, and full of bustle, as are all the others, which terminate in the great square. An academy of the belles lettres was esta-
blished here in the year 1752. Here was a palace, in which Philip II. was born, now reduced to bare walls; 84 miles N.N.W. of Madrid. N. lat. 41° 42'. W. long. 4° 47'.
VALLADOLID, a town of South America, in the audience of Quito; 40 miles S. of Loxa.—Alfo, a town of Mexico, in Yucatan. N. lat. 19° 50'. W. long. 80° 30'.
VALLADOLID, or Comayagua, a town of Mexico, in the province of Honduras; the fee of a bishop, who takes the title of bishop of Honduras. N. lat. 14° 30'. W. long.
88° 16'.

VALLAIS. See VALLAIS.
VALLANCE, a town of France, in the department of the Gers; 4 miles S. of Condorn.
VALLAR, VALLARIS, formed from vallum, a flake
with branches, of which they made the palisade of a camp, called loric, in Antiquity, an epithet given to a kind of crown, which the Roman generals bestowed on him who, in attacking the enemy's camp, first broke in upon the line of palisades.
The corona vallaris was the same with what was otherwise called corona castrensis, from castra, a camp. Aulus Gallius affures us, that it was of gold, as the mural and naval orders also were: yet, though they were made of that precious metal, they were not the most valued; for Pliny, lib. xxii. cap. 3. gives the preference to the corona ob-
fusionalis, which was yet only of gramin. or grafs. See Crowns.
VALLARIOS, in Geography, a town of Spain, in Ara-
gon; 15 miles W. of Balbastro.
Eff. Ch. Corolla falver-shaped; mouth and tube per-
vious, without scales; limb in five obtuse segments. Sta-
mens prominent; filaments inserted into the throat, very short, with a felifer tube externally, at the top; anthers arrow-shaped, adhering to the stigma. Germin of two cells; style thread-shaped; stigma connate-ovate. Scales at the base of the germ are combined below, fringed at the points. /Follicles . . . .
Obf. Mr. Brown remarks, that this, the Plu Pergu-
lanus of Rumphius, was considered by Linnaeus as the first
species of his genus Pergularia." It does not, however, be-
ton to the same order with the plant that afforded his ge-

C
neric character, and so which the name has been since generally applied. See Pergularia.

1. V. Pergularia. Sweet Bower-vine. Burm. Ind. 51. (Flores pergularus; Rumph. Amboin. v. 6. book 7. 51. t. 29. f. 2.) Carack nullius of the Malayas. Pergularia glabra; Linn. Mant. 55. Wildl. Sp. Pl. v. 1. 134.)—This, the only known species, is a native of Java and Ambonaya, used for bowers and trellis-work, as it makes a very thick shade. The Malay women are fond of adorning their hair with its fragrant flowers. The flem is perennial, shrubby and twining. Leaves opposite, flalked, ovate, acute, entire, thick and shining, five inches long, two and a half or three wide, with strong pale veins. When the leaves or twigs are wounded, they discharge a thick, viscid, yellow milk. Flower-fasts from between the footstalks, fokced, cornybofe. Flowers white, and highly fragrant, compared by Rumphius to thofe of Jofmine, (probably Jasminum Samars.) but having a shorter tube, with five fanging bodies in the middle. He speaks of the fcent of these flowers as too strong for Europeans, though highly esteemed by the natives of the country where they grow.

Valle, Pietro Della, in Biography, a Roman pat- rician, who, in the year 1614, commenced his travels into Egypt, Turkey, Peru, and India. At Bagdat he felled in love with a young female of the name of Chriftiana Febis of Chriftiana Febis; and married her. She accompanied him in his journey, and on his return towards Italy, she died near the Perian gulf. The los of fo much affected him, that he had her remains em- balmed, and carried them with him during his fubfquent travels, and on his return to Rome, they were magnificently interred in the church of Ara Coeli; and he himself pron- nounced her funeral elogy, which was printed. The ac- count of his travels, written by himself in Italian, and con- tained in fifty-four letters, was published at Rome in 1650. They have been often cited as authority, though not defi- nite of marks of credulity, and still bear a repectable rank among books of travels. The iftyle is pure and elegant, though the narration is prolix. Doni has spoken of him in terms of high commendation, and represents him as well ac- quainted with the Oriental languages, and with music. He wrote on other fubjeds besides his travels, and was a member of the Academy degli Umorifti. His fcond wife was a Georgian, attached to his fift wife, and the companion of his travels. Moreri.

For the opinion of this agreeable writer concerning the music of his own times, we refer to the article Orifting, inferting here his account of the manner in which the first opera, or musical drama, was exhibited at Rome, which is ex- tremely amusing and curious. "Though no more than five voices, or five instruments, were employed, the exact num- ber which an ambulant cart could contain, yet Steele afforded great variety: as, besides the dialogue of fingle voices, sometimes two, or three, and, at last, all the five fongs to- gether, which had an admirable effect. The music of this piece, as may be seen in the copies of it that were afterwards printed, though dramatic, was not all in fimple recitative, which would have been tiresome, but ornamented with beau- tiful pavages, and movements in measure, without deviating however from the true theatrical iftyle; on which account it pleased extremely, as was manifefted from the prodigious con- course of people it drew after it, who, so far from being tired, heard it performed five or fix feveral times; there were fome even who continued to follow our cart to ten or twelve different places where it flp, and who never quitted us as long as we remained in the ftrée, which was from four o'clock in the evening till after midnight."

This narration seems to furfh a curious circumstance to the history of the stage, which is, that the first opera, or musical drama, performed in modern Rome, like the firft tragedy in ancient Greece, was exhibited in a cart. It has been imagined by many of the learned, that the recitative in modern opera is a revival of that species of melos in which ancient dramas were sung; and here the moveable stage on which it was performed, like that used by Théfipis at Athens, furnishes another resemblance.

"—— Plautus vestale,
Poemata Théfipis." Hor.

Della Valle, after having proved that the singing of his time was better, and the compositions more varied, more rational, and imical to poetry, than the more ancient, pro- ceeds to speak of instrumental music; and after discriminating the different kinds of playing on an instrument, in a folo, in a full piece, in accompanying a voice, or leading a band; he fays, he muft agree with his friend, that folo playing, however exquisif and refined, at length tires; and that it had frequently happened to organists of the highest chufs, when loft and immerfed in carrying on a happy sub- ject of voluntary, to be flienced by a bell; which never happened to fingers, who, when they leave off, difpleafe the congregation or audience, to whom their performance seems altogether too long.

After difcufling instrumental music, he comes to finging, and this he considets in folo fongs, and in fume of many parts. His friend, among the sopranis, or treble voices, of his youth, had greatly praised the falaffi who used to fing in the pope's chapel, and elsewhere; and Della Valle fays he remembered one of them, Gio. Luca Falaffi, who had great execution, and went up to the clouds; and mentions Orazietto, a very good finger, either in a falfi or tenor; Ottaviveccio and Verovio, famous tenors, who all three fung in his cart. "However, thefe," he adds, "trills, graces, and a good portamento, or direction of voice, excepted, were extremely deficient in the other requifes of good finging; such as piano and forte, swelling and diminifhing the voice by minute degrees, expression, affifling the poet in fortifying the femfe and paffion of the words, rendering the tone of voice cheerful, pathetic, tender, bold, or gentle at ple- nure: thefe, with other embellifhments in which fingers of the prefent times excel, were never talked of even at Rome, till Emilio del Cavaliere, in his old age, gave a good speci- men of them from the Florentine fchool, in his oratorio, at the Chiefa Nuova, at which I was myfelf, when very young, prefent."

What follows is extremely curious and fatiafaftory con- cerning a delicate point of musical history, which is, the first eftablifhment of evirati in the pope's chapel, and the ufe of them in early operas.

It is astonishing how much sooner Della Valle got rid of the pedantry of the then old fchool, than any of his contemporaries. He manifefts as much good taste in his reflctions on imitative and dramatic music, as any writer of the laft century.

Della Valle's biographers seem to have known nothing of the correpondence with Guidiccioni, or of his skill and good taste in music. This agreeable and intelligent traveller died in 1652, aged 66.

Valle Calamocibra, a town of South America, in the province of Tucuman; 40 miles N.E. of St. Louis.

Valle Ruffio, a town of the island of Corfica, in the district of La Porta.

Valle di Spagna, a town on the east coast of the island of Cephalonia.

VALLEA, in Botany, owes its name to Mutis, who sent the plant to Linnæus. In the Supplemimentum it is said to commemorate a person named Valle, "praised by Allioni." No one having vouchsafed to indicate where this praise is bestowed, and De Theis having transferred the honour of the present genus, with true French patriotism, to one of his own countrymen, Robert Valle, of Rouen, who published, in 1500, some Commentaries upon Pliny, we have thought it necessary to inquire into the matter; especially as the genus is well worth claiming. In a note to Allioni's Rariorum Pedemontii Stirpium, Specimina primorum, page 23, the mystery is unravelled, by a narrative, of which the following is the substance. Dr. Valle, a physician of Turin, a botanist of no common merit, after having attentively investigated the plants around that city, and those of the neighboring alps, was led by an ardent love of botany, and other branches of natural history, to procure, in 1747, the appointment of physician to the army in Corfica, in order to examine the productions of that country. There he made ample collections of plants, seeds, shells, insects, and other things worthy of notice. But being more anxious to acquire knowledge than to take care of himself, the heat of the climate threw him into a violent fever, which carried him off in three days. His dried Corfican plants, falling into the barbarous hands of ignorant people, were all destroyed. Whatever his friend Allioni could meet with, by the affilience of the family, he purchased; and thus became possessor of numerous specimens, gathered by Dr. Valle about Savona, as well as in various parts of the alps, of which he had drawn up a description, after Tournefort's system; but this was completed no further than the first four chapters.—The name of Valle therefore deserves to be embalmed with thofe of Bartch, Borone, Lippi, and other premature martyrs to botany, who have justly been thought worthy of such an unfaidng memorial.—Linn. Suppl. 43, 472. Schreb. Gen. 452. Willd. Sp. Pl. v. 2. 1212. Juss. 434. Poiret in Lam. Dict. v. 8. 318.—Clafs and order, Polyandria Monogynia. Nat. Ord. Tiliaee, Juss.?

Gen. Ch. Cal. Perianth inferior, of one leaf, in four or five deep, ovate, folutated, coloured, dissected segments. Cor. Petals four or five, obovate, three-cleft, rather larger than the calyx. Nectary a flattish, undulated, shining, coloured border, under the germen. Stem. Filaments numerous, 30—40, awl-shaped, flattish, coloured, incurved, shorter than the calyx, inferted into the receptacle, beneath the nectary; anthers linear, erect, with two pores at the summit. Pet. Germen superior, ovate; style nearly cylindricaJ, as long as the calyx; stigma four or five slender divisions. Peric. Capsule with four or five angles and as many valves, each valve appropriated to two cells. Seeds several.

Eff. Ch. Calyx in four or five deep segments, inferior. Petals four or five, three-cleft. Stigmas four or five. Capsule with four or five valves, twice as many cells, and several seeds.

1. V. dipetala. Linn. Suppl. 266. Willd. n. 1.—Native of the colder parts of New Granada. A tree, twelve feet high, with round, fritated, leafy, hairy branches. Leaves alternately, on hairy filaments an inch long, spreading, simple, heart-shaped, acute, entire, two or three inches long and half as broad, fiddle-ribbed, beautifully reticulated with innumerable veins; smooth and shining above; paler, clothed with tawny hairs, especially about the rib and larger veins, beneath. Stipites rather large, leafy, kidney-shaped, entire, stalked, in pairs at the base of each footstalk, and clasping the stem above it. Flowers blood-red, near an inch in diameter, in forked, cymose, hairy, axillary, and terminal panicles, shorter than the leaves.—Linnæus cites Mutis, Amer. v. 7. t. 10, by which botanists have been led to understand, that Mutis had published an important work on American plants, extending to seven volumes, at least. But in fact no such work exists. The reference is, in every point, erroneous, and alludes merely to a collection of thirty-two Indian-ink drawings of Mexican plants, sent by that learned Spaniard, with numerous dried specimens, to Linnæus. (See Mutis.) From his drawing of the Vallea, compared with the specimen, we have, as our readers may observe, ventured to correct some part of the generic characters. By that drawing the feet-well appears to have four valves, (sometines, it seems, varying to five,) each of which has flexed edges, besides a central partition; and these, all meeting at a central column, may easily be conceived to form a capsule of eight or ten cells, explaining the strange expression in the Supplemimentum, of "clipsibus bicliniataribus." Several circumstances indicate the affinity we have hinted above, of this genus, to Jussieu's Tiliaeae; see that article.

VALLESIA, in Botany, thus named in the Flora Peruvian a, after Dr. Francis Valles, physician to Philip II. of Spain, and author of a work, amongst others, on the plants of the holy scriptures; free from heresy, no doubt, if not from error.—"Fl. Peruv. v. 2. 26. t. 151. f. B."—Poirét in Lamarck Dict. v. 8. 319.—Clafs and order, Pentandria Monogynia. Nat. Ord. Compositae, Linn. Aposince, Juss.

Gen. Ch. Cal. Perianth inferior, small, of one leaf, in five acute segments. Cor. of one petal, funnel-shaped; tube much longer than the calyx, swelling upwards; limb flat, in five ovate, equal, spreading segments. Stam. Filaments five, very short, inferted into the upper part of the tube; anthers arrow-shaped, in the mouth of the corolla. Pet. Germen superior, oval, cloven; style thread-shaped, as long as the tube of the corolla; stigma obtuse. Peric. Drupes two, oval, obtuse, disarticulated, of one cell. Seed. Nut solitaire, oval, woody, fibrinous, fritated, with a solitary kernel.

VALLEY.

lanceolate, acute, entire, smooth, shining, single-ribbed, two or three inches long and one broad. Panicles or cymes small, forked, opposite to the leaves. Flowers small, white. Fruit whitish. *Poires, after the Fl. Peruv.*

VALLET, in Geography, a town of France, in the department of the Lower Loire; 12 miles E. of Nantes.

VALLEY, in Natural History and Geology, is a tract of ground bordered by hills or mountains on two opposite sides, between which it extends in a straight or winding line. If the valley be short, and the length is not much greater than the breadth, it is called an opening, or pafs, through a mountain or chain of mountains.

Large valleys have generally a number of small valleys joining them, like branches to a main trunk. In almost every valley there is either a lake or a river, and the magnitude of the river bears some proportion to the valley. The lower end of a valley, where the river empties itself into a larger river or lake, or into the sea, is generally much broader than its upper or higher end. Some valleys are nearly closed in at each end, forming elliptical hollows in mountainous districts. Such valleys have once been lakes, but the water having worn itself a paffage at the lower end, has reduced the lake to a small stream in the middle, or the lakes have been filled up by the debris from the adjoining mountains.

Sauflure divides valleys into two orders, which he calls longitudinal valleys and transverse valleys. Grand mountain chains are commonly formed of many ranges of mountains running parallel to the highest or central range, each range diminishing in height as its distance from the central range increases. It is between these parallel ranges that longitudinal valleys are situated. Sauflure cites the valley of the Rhone as a striking example of this kind of valley.

Transverse valleys are those openings which communicate between the longitudinal valleys, either at right angles with them, or obliquely. It is observed by Patra, that the transverse valleys which cut through the central range of mountains, are sometimes nearly horizontal, at least for a short distance; but those which cut the collataral chains have always a more or less rapid descent; and as they are frequently excavations formed by water-courses, they sometimes present corresponding saliant and retiring sides, like the valleys in secondary mountains; but it is evident that this effect is accidental.

One of the essential characters of longitudinal valleys is, that their direction is parallel with the line of bearing, or range of the beds of which the mountains are composed. Transverse valleys cut through the beds in the direction of their line of dip or inclination. See Plate II. Geology, fig. 2, in which the side of the mountain fronting a represents the beds of a mountain in their line of bearing; and a spectator placed at the station a, may be supposed to be placed in a longitudinal valley, in which the edges of each bed in the opposite mountain would appear to range horizontally. The same appearance would present itself to the spectator placed at B, fig. 5. A transverse valley cutting through the beds at right angles to the former, would shew the true dip or inclination of each bed to a spectator placed at b, in the former fig. 2. The side E of the mountain represents the direction of a longitudinal valley, the side G, the direction of a transverse valley.

The Alps present many longitudinal valleys. The valleys in the Pyrenees are transverse. This difference has been suppos'd to arise from the central parts of the Pyrenees ascending more precipitously above the lower beds; hence the waters, falling with great impetuosity, have cut paffages through the lower beds in direct lines, and taken the shortest course to the plains below.

In the Alps, the currents, being less violent, have followed the course of the longitudinal valleys, which had been traced out by nature in the original formation of those mountains.

Some mountain groups are disposed in forms nearly circular, so as to include great tracts of flat country, as is the case with Swabia, Hungary, Transylvania, &c. These circular bains or valleys have formed lakes, when the relative level of the ocean was much higher than at present; and on infpecling the belt maps, where the inequalities of the surface are delineated, we may be led to suppose that a considerable part of Europe has once been covered by these lakes, the present mountain chains forming the boundaries. The Rhone and the Rhins, flowing among the mountainous circular valleys in their course; and the river Don, in Aberdeen, has its course through valleys of this kind. At the mouth of the Don, the rocks confine it to a narrow channel, and give to it an aspect which would convey the idea of its flowing through a mountainous and rugged country, where no space was left for forming even a commodious road along its banks; but on ascending it for about one mile, the hills recede on each side so as to form a fpacious vale, through which the river flows in a flow majestical course for many miles. Nor is the prospect here uniform, but agreeably diversified, the hills above Iverury approaching again close to the river, through which it seems to have forced its way with difficulty; then all at once it opens into another fpacious vale, from which the hills recede on either hand to a great distance; then it closes again; and after another temporary confinement among rocks, hills, and woods, its waters once more open into another plain of great extent. Such is the general character of this river.

The Danube, whose history has been so well illustrated by the count de Margili, has four sources, one of which, the river Swabia, from whence it paffes through Swabia, Bavaria, Austria, Hungary, and Walachia, into the Black sea. Swabia is a great circular valley, from which the Danube escapes by a narrow opening into Bavaria: during its progress through Bavaria, it paffes through several circular valleys into Lower Austria, which is also a circular valley. It flows through Austria, and at Pretzburg, where the valley is nearly shut up, it forces its way through rocks and hills into Hungary, which is one of the most extensive circular valleys in Europe. At the lower extremity of Hungary, the river is again forced to seek its way through a narrow rocky channel to Orfova, which is the only opening between Hungary and Walachia. It now continues its course through Walachia, and at length falls into the Black sea. We have a continuation of this chain of valleys, although still filled with water, in the Black sea, the sea of Marmora, and the Mediterranean.

The valley of Cashmera presents one of the most striking examples of a circular bain or valley, containing a small lake, which has probably once filled a confiderable part of the great cavity formed by the surrounding mountains. "This happy valley," says Mr. Pennant, "this Hindoostan paradise of the Indian poets, is of an oval form, about eighty miles long, and forty broad, and is suppos'd to have been once entirely filled with water, which having burst its mound, left the vale nourished to the most dilatant ages by the fertilizing mud of the river, which fed its expanse. This delicious spot is surrounded by mountains of vast height and rude aspect, covered with snow, and eneched in glaciers, in which this enchanting jewel is firmly fet."

The formation of valleys has been by some philosophers acribed
VALLEY.

afcribed almost exclusively to the action of running water. That many of the present valleys have been so formed, is rendered probable by various existing phenomena, but other causes must also have operated. Among these we may enumerate the original inequalities of the surface; these were indeed necessary to make the waters flow in a particular course. The sudden elevation of parts of the earth's surface, and the subsidence of other parts, are also proved by the fractures and dislocations of the strata which mountainousdistricts almost everywhere present. There are likewise evident marks that the ocean has been thrown sud- denly, and with great violence, over our present continents, tearing away and transporting to distant countries various parts of the surface, scooping out hollows in the softer strata, breaking down the boundaries of immense lakes, and thus changing the course of rivers, and opening new valleys where none before existed. Great and sudden risings of the sea have been known to take place in our times, by the agency of submarine fire operating on a small extent of the globe; and we have only to conceive the same agent operating more powerfully, to explain the changes which may have taken place from the ocean suddenly rising and sweeping over a large portion of the globe. See System of Geology.

The theory of the formation of valleys by the action of rivers has been supported by Dr. Hutton and professor Playfair. "Every river (says the latter) appears to consist of a main trunk, fed by a variety of branches, each running in a valley proportioned to its size, and all of them together forming a system of valleys communicating with each other, and having such a nice adjustment of the depressions, that none of them join the principal valley either in too high or too low a level, a circumstance which would be infinitely improbable, if each of these valleys was not the work of the stream that flows through it. When the usual form of a river is considered, the trunk divided into many branches, and these again subdivided into an infinite number of smaller ramifications, it becomes strongly impressed upon the mind, that all these channels have been cut by the waters themselves, and that they have been slowly dug out by the washing and erosion of the land." This is an accurate description of the structure of many valleys, but there are others in which the smaller valleys do not join the larger at the same level, but terminate abruptly, and the rivers which flow through them fall in cascades to the lower valleys. The valley of Wattenlagh, in Cumberland, is a striking instance of this kind. The lower extremity joins the vale of Keswick, in which the lake of that name is situated, but it does not enter it at the same level, but terminates in a precipice between two cliffs, down which the water is thrown, forming the cataract of Lowdreda, which empties itself into the lake.

Where the corresponding strata on each side of a valley have nearly the same elevation as is represented in Plate III. Geology, fig. 4, it is obvious that the excavation between the opposite hills has been formed by water which has once flowed at a much higher level than at present. Also, where the strata on the opposite sides of a valley have the same angle of inclination with the horizon, (see Plate II. Geology, fig. 5) we may infer that it has been excavated by water; but where the strata on the sides of a valley dip in an opposite direction, or have a much greater dip on one side than on the other, the original formation of the valley may be attributed to the elevation or sub- sidence of the strata, forming a fissure through which the water has run, and in which the course of ages has worn a channel and enlarged the passage. Some circular valleys and lakes may have originated in the subsidence of the surface, forming a large cavity, the sides of which are gradually worn down in many parts into gentle slopes. An accurate exam- ination of the true line of dip of the beds, can alone dis- cover to which of these causes the formation of any particular valley can be ascribed; and it is frequently more difficult to ascertain the true angle of inclination than is generally supposed, and still more difficult to determine whether a slight variation in the angle is occasioned by a fracture, or by an original inequality or waving of the stratum.

That lakes are pitting to the state of valleys, and that many of the present valleys have been lakes, is obvious to the most common observer who will attend to the appearances which they present. A lake, says professor Playfair, is but a temporary and accidental condition of a river, which is every day approaching its termination; and the truth of this is attested not only by the lakes that have existed, but by those which continue to exist. Where any considerable stream enters a lake, a flat meadow is usually observed increasing from year to year: the soil of this meadow is deposited in horizontal strata; the meadow is terminated by a marsh, which marsh is acquiring solidity, and is soon to be converted into a meadow, as the meadow will be into an arable field. All this while the sediments of the river makes its way slowly into the lake, forming a mound or bank under the surface of the water, with a pretty rapid slope towards the lake. This mound increases by the addition of new earth, mud, and gravel, poured in over the slope, and thus the progress of filling up gradually advances. By an accumulation of vegetable matter in shallow lakes, marshes and peat bogs have been formed at the bottom of valleys where the waters have not flowed with sufficient rapidity to drain away the moisture. These are common in various parts of the Highlands, and in Ireland. The filling up of lakes, and the enlargement of valleys, by the proclivity above described, may be distinctly seen in the vicinity of the lakes of Cumberland and Westmorland. Larger lakes exemplify the same process. Where the Rhone enters the lake of Geneva, the beach has been observed to receive an annual increase; and the Portus Veltini, now Prevallais, which is at present half a league from the lake, was formerly close upon its bank. Indeed the sediments of the Rhone appear clearly to have formed the valley through which it runs, to the distance of about three leagues from the place where the river now discharges itself into the lake. The ground there is perfectly horizontal, composed of sand and mud, little raised above the level of the river, and full of marshes. The deposition made by the Rhone, after it enters the lake, is visible to the eye, and may be seen falling down in clouds to the bottom.

Where lakes are situated at a considerable elevation above the sea, or the adjacent country, they may be emptied by the wearing down of the strata which forms the outlet. Many of the North American lakes are connected by small strata or rivers, which have a rapid descent. One of them are prodigious water-falls, which are constantly enlarging the passage from one to the other, and will ultimately drain the upper lakes. The falls of Niagara are observed to be progressively shortening their distance from the upper lake, since the banks have been inhabited by Europeans; and when it has completed its progress, the upper lake will become an extensive valley, surrounded by rising grounds, and watered by a river or smaller lake, which will occupy the lowest situation.

Valleys constitute the most fertile and habitable parts of almost
almost every country. Their superior fertility is derived from a constant supply of fresh soil, and from natural irrigation, and a more equal temperature; the vegetation being sheltered and protected from the boisterous winds that sweep over extensive plains, and the more elevated parts of the globe. It has been observed, however, that low valleys are not so favourable to the longevity of the human race as dry and mountainous districts.

Valley of Heroes, in Geography, a name given to the delightful plains of Oujan, which are said to produce the finest pasture in Persia. It is so called by the natives, from having been formerly the favourite hunting park of the kings and heroes of Iran, and particularly of Bahram Gour, who had many palaces of different colours in the neighbourhood. This prince, passionately devoted to the chase, took his name from the gour khur, or wild ass, with which this valley abounds. In one of the roads from Persepolis to Ispahan there is a pass or defile, called Iman Zada Ishmael, two furlongs in length, and commencing at the 36th mile from Persepolis, which leads into the above-mentioned plains.

Vallets, in Building, denote the gutters over the sleepers in the roof of more buildings.

Valli, in Ancient Geography, a people of Aisa, upon the Gordian mountains, near the Caucassian gates, which were in these mountains, according to Pline.

Valli, in Botany, Jiff. Gen. 567. Rheede Hort. Malab. v. 7. t. 6—11, the name of several East Indian climbing shrubs, which Julliff confiders as belonging to the genus Vitis, hereafter to be described in its proper place. Karetà Valli of the same volume, t. 45, is referred by him to the neighbouring genus Cifius.

Valli, in Geography, a town of Naples, in Lavora; 12 miles E.S.E. of Capua.

VALLIERE, a town of France, in the department of the Creuse; 6 miles S.W. of Aubusson.

VALLIES, Four, Distrit of, otherwise called The Distrit of Pignerol, a province of Piedmont, bounded on the north by the marquifate of Susa, on the west by France, on the south by the marquifate of Saluzzo, and on the east by Carmagnola. The four vallies are those of Peroua, Lucerna, St. Martin, and Angroina. The province is about 24 miles long, and from eight to eleven broad. The principal towns are Pinerolo, Lucerna, Peroua, St. Martin, and Feneffrila. These vallies are watered by the Clufon, and several other smaller rivers; they are all surrounded with mountains and sharp rocks, in which are found white hares, foxes, pheasants, partridges, wolves, and bears; and in the most lofty of the neighbouring alps is found the marmotte, a creature something larger than a rabbit, but more of the nature of the badger; the chamois; and the bouquetin, an animal something like a goat or chamois, but more fleet than either. Among the tame animals is the jument, produced by a bull and a mare, or a bull and a sheaf. The vallies are fertile in pattarine, and the mountains in fruit, particularly celnuts. These vallies are celebrated for the cruel persecution of the inhabitants, who were called Waldencif, on account of their religion, about the year 1655. But now they enjoy in peace the worship they embraced, though they have a Catholic church in each parish. The number of inhabitants is reckoned at about 8000, of whom 7000 are supped to be Protifantists.

VALLIS, in Ancient Geography, a town of Africa Propria, upon the route from Carthage to Cirta, between Sicilia and Corena, according to Antonine's Itinerary.

VALLIS Acher, Valley of Acher, a valley of Palestine, north of Jericho.

VALLIS Aijabu, Valley of Aijabu, a valley of Palestine, in the tribe of Dan, between Thammath and Bethhemeth.

VALLIS Artificum, Valley of Graffina, a valley of Palestine, in the tribe of Benjamin, near Jordan.

VALLIS Arunudin, Valley of Reeds, a valley of Palestine, near the Dead fea.

VALLIS Benedictionis, Valley of Bluffing, a valley of Palestine, in the tribe of Judah, west of the Dead fea.

VALLIS Carimiana, a place of Pannonia, on the route from Sopianae to Aquincum, between Pons Socrorum and Corvinum or Gorgium. Anton. Itin.

VALLIS Cadaverum, Valley of Tophet, the slaughter-house of Jerufalem. It lay south of the city, in the valley of the children of Hinnom. It is said, that a fire was constantly kept here for burning the carcases, and other filth, that were brought hither from the city. (Iaïlah, xxx. 33.) Others think, that the name of Tophet is given to the valley of Hinnom, on account of the sacrifices offered there to the god Moloch, by beat of drum, to drown the cries of the consuming children; a drum in Hebrew being called tops.

VALLIS Domittiniana, a place of Lower Moria, upon the route from Atrabium to Nicomedias.

VALLIS Gibonis, Valley of Gibon, a valley of Palestine, west of Jerufalem, fo named from the fountain of Gibon, whose spring is in this place, and runs from west to south.

VALLIS Eumona, a town of Judea, in the tribe of Benjamin.

VALLIS Jeraxel, a valley of Palestine, having the chain of mountain Hammon to the north-east.

VALLIS Illuvris, the Illuvris Valley, a valley of Palestine, near Sichem. This was the vale or plain of Moreh.

VALLIS Montium, the Valley of Mountains, a name given by the prophet Zechariah to the valleys round about Jerufalem, where the inhabitants of that city took shelter, when the city was besieged by the Romans.

VALLIS Rephasim, or Valley of the Giants, called in Greek the Valley of the Titans, and in the Vulgate, the Valley of the Giants (2 Sam. xxii. 13.), lay near Jerufalem, and belonged either to the tribe of Judah, or that of Benjamin.

VALLIS Salinas, the Valley of Salt or Sal-sites, generally placed in the southern part of Idumaa, S. of the Dead fea, but situated according to Calvin, in the easter part of Idumae, between Tadmor and Bozez.

VALLIS Syrophulcia, the Vale of Woods, a valley of Palestine, in which were situated the cities of Sodom and Gomorrah, and where the Israelites, or the Dead fea, was formed. This was called the vale of Sidim.

VALLIS Tabernaculorum, the Valley of Succoth, or Vale of Teuts, lay beyond Jordan, near the city of Succoth. The psalmist puts the valley of Succoth for the whole country beyond Jordan.

VALLIS Terebintus, called the Valley of Elah (1 Sam. xvii. 2) or of the Oak, lay S. of Jerufalem, towards Sochoh and Azekah. The valley of the Terebinthus is also a name given to the valley of Manre, on account of the terebinthus under which Abraham entertained the angels.

VALLISNERI, ANTHONY, in Biography, a celebrated Italian naturalift, was born of a good family, May 3d, 1661, at the calle of Trellicio, of which his father was governor for the duke of Modena. He was first instructed in the rudiments of the learned languages by the Jesuits, at Modena, and was afterwards taught rhetoric, and the Ariflotelian philosophy, under the same aupsites, at Reggio, where he defended his theses on that subject in 1682. Nevertheless he began, even at this period, to be difsatisfied with the prevailing fystem, which he called a philofophy of words; and happening to have a more liberal and enlightened preceptor
preceptor than usual, his attention was directed to natural and experimental philosophy, and the then prevalent hypotheses of Des Cartes. His tutor Biagi, a Jesuit, had the good sense and honesty to avow, that the philosophy of Aristotle might suit theologians and monks, but that he himself knew many able and distinguished men, at Bologna, and elsewhere, who, far from being indebted to that great person, never thought of his doctrines but to refute them. Vallisneri therefore removed to Bologna in 1683, and very soon gave up theories and hypotheses for the observation of nature. Here the great Malpighi, to whose particular favour he was recommended by the princes of the house of Este, directed his anatomical enquiries, and from him he received, at his first introduction, a valuable lesson on the preemption of thec physicians, who boast of a specific for every disease. The learned and experienced Malpighi, confined to his bed by illness, declared that he was unable to cure his own disorder. A candid confession, which then astounded his hearer; but of the truth of which Vallisneri declared himself subsequently more and more convinced by his own practice of physic, when he found the most boasted specifics daily deceiving his expectations.

The father of the young Vallisneri, himself a doctor of laws, offered his son a choice between law and physic; but his earliest inclinations and inquiries were too much allied to the latter profession to allow of hefitation. An anatomist of animals from his youth, he devoted himself to affiduously to dissections, in the instructive and flourishing school of Bologna, that his health became a sacrifice to his curiosity, and Malpighi was obliged to check the dangerous ardour of his promising pupil. Vallisneri would doubtless have graduated in this famous university, then in its meridian glory; but at the time when this should have taken place, the duke of Modena put forth an edict, prohibiting his subjects from taking degrees, except at Modena or Reggio. Vallisneri chose the latter, and took his doctor’s degree in 1684; but in order to study with advantage the necessary sciences of chemistry and botany, as well as to improve himself in practical surgery and physic in the hospitals, he was obliged to return to Bologna; as our doctors of Cambridge or Oxford find it expedient to accomplish themselves in London and Edinburgh. He spent about three years more under the auspices of Malpighi, who at length dismissed this favourite pupil with the sound advice of studying nature, and communicating matters of fact. “Systems,” said he, “are ideal and mutable. Observation and experience are solid and unchangeable.”

The years 1685 and 1686 were usefully passed at Padua, Venice and Parma, and at length Vallisneri settled as a physician at Reggio. Here he planted a botanical garden, and employed his leisure hours in excursions among the neighbouring mountains; to collect herbs, minerals and petrifications; to observe the strata of the rocks, and the origin or nature of the various forests; as well as to take the pleasures of the chase, of which he was very fond. The first particular object of investigation to which this ingenious philosopher devoted his attention, was the anatomy of the Silk-worm, by which he was led to the study of the metamorphoses and generation of other insects. Malpighi and Redi were his guides; but he soon found, in the intricacies to this new and reconduit course of enquiry, that he was able to extend their information, and correct some of their remarks. He gave his discoveries to the world in the form of two Dialogues in Italian, proposed to take place between Pliny and Malpighi, on the arrival of the latter in another world. These brought great reputation to their author, both for the value of their contents, and the elegance of their language and composition. They introduced him to the acquaintance and correspondence of several learned men, engaged in similar studies; among others to that of our distinguished Dr. Martin Lister. He was soon afterwards invited to Padua, where he rose successively from one medical professorship to another, till he obtained, in 1711, the first chair of the Theory of Medicine. When Vallisneri first took his place among the teachers of physic in this long-established university, he was well aware of the caution necessary in opening the eyes of the blind, and in teaching the lame to walk. He had already exercised his own powers, and was a proficient in the practical, or experimental, philosophy, of medicine, as well as of anatomy and physiologv. But those accustomed to lean upon others, do not at once acquire, or even desire, the use of their own faculties. Established bodies naturally cling to established authorities, and it perhaps becomes them to be cautious of embracing, without due deliberation, any unauthorized novelty. To this duty, whatever others they may neglect, they must be allowed to be piously attentive. Nothing therefore could be more judicious than the subject of our new professor’s first thesis, when he took the chair on the 14th of December, 1700; that “the Studies of the Moderns do not overturn, but confirm, the Medical knowledge of the Ancients.” He pointed out in Hippocrates traces of the greatest discoveries, which the moderns by their superior opportunities had fully explained, such as the circulation of the blood; and thus without invalidating the merits of the latter, he dexterously confirmed the authority of the former, and flattered, instead of alarming, their disciples. He thus stimulated them to enlarge the sphere of their own knowledge, so that by improving the practical sciences of chemistry, anatomy, &c. they might farther elucidate what the ancients had not fully understood or explained. In the progress of his lectures, however, Vallisneri was too judicious, and too honest, to sacrifice truth, to any ancient or modern authority. He attacked, without feruple, Avicenna’s theory of fevers, and the erroneous practice founded thereon; as well as the doctrines of the putrefaction of the humours, the sanguification of the liver, with many mechanical hypotheses of the old school. All this did not indeed pass without animadversion, especially the new doctrine of glandular secretion; but Vallisneri, supported by truth and experience, finally prevailed, and wrought a great change in the theoretic medicine of his day. Improvements in practice followed of course; and whenever the enlightened teacher met with any troublesome opposition, or, as usual, was attacked with misrepresentation and clamour, he found an able protege in Frederick Marcello, procurator of St. Mark, who being charmed with his earlie writings, had first recommended him to his appointments at Padua.

The intervals of his acadeimal duties were often devoted by Vallisneri to rural excursions, for the improvement of his knowledge in natural history, as well as for the restitution of his bodily and mental powers, amid the wild and majestic, or the variously beautiful, scenes of nature, which lay so profusely within his reach. In the summer of 1704 he visited the recesses of the Apennines, and climbed their stupendous precipices. The scenery which inspired the genius of Salvator Rosa, enlarged the mind, and enriched the acquisitions, of our philosopher, and he defended, like a fertilizing river, to benefit the world below. The following year, he undertook a less laborious journey, to visit his literary friends at Lucca, Pisa, Leghorn and Florence, and was invited by prince Ferdinand of Tuscany to Pratalino, where he met with a snall flattering reception, the prince’s hospitality.
hospitality being extended to the peripatetic, as well as literary, 
accommodation of Vallisneri at Florence itself, where every 
door and cabinet were opened to him. From Leghorn he 
proceeded to Genoa, not without the usual adventure of a 
shipwreck of his wretched felucca, by which accident he 
had the advantage of seeing for the first time a noble Date 
Palm, in the open ground. He returned from Genoa to 
Padua by land. These and many similar excursions, in 
several following seasons, were productive of much informa-
tion to a man, who could not pursue the most beaten track 
without picking up something. Indeed his line of study 
was new at that period. He contributed to open a new 
world to microscopic observers, and to direct their en-
quiries to advantage. He had by this time collected an 
ample museum, and choice library, both of them the more 
valuable and useful, for being collected by himself with 
some particular object.

His studies were not impeded nor embittered by domestic 
cares or chagrin; for though he married in 1692, and 
his wife brought him eighteen children, she was a woman of 
prudence and good fortune; she directed his family in such a 
manner as to render his home comfortable and happy. Of 
the children, four only survived their infancy; a son who 
bore his father's name, and inherited his activity of disposi-
tion, and three daughters, two of whom became nuns at 
Padua. The third, named Claudia, a woman of rare 
talents, and the highest moral worth, remained unmarried at 
home.

In the beginning of 1728, Rinaldo I., duke of Modena, 
sent Vallisneri an unlicensed patent of knighthood, for him-
self, his son and their descendants. This honour was the 
more just, as he had, eight years before, declined an invitation 
from pope Clement XI. to become physician to his 
holiness in the place of the famous Lancii. He had also 
refused to accept, from king Victor Amadeus, the appoint-
ment of first professor of physic, at Turin, with a very 
large stipend. Nor were academical honours wanting to his 
fame. He was associated with the Academy Nature Curio-
forum, the Royal Society of London, and almost every 
learned body in Italy. Thus in the indefatigable pursuit of 
knowledge, and well-merited fame, he completed his sixty-
eighth year. On the 12th of January, 1730, he was at-
tacked with a sort of epidemic cacharr, accompanied with 
great debility, which, falling on his lungs, carried him off 
on the 18th. He was interred in the church of the Eremi-
tani at Padua, where his son erected a monument to his 
memory with the following just and elegant inscription.

D. O. M.
Antonio Vallisnerio
Artsi Medicei afflorti eximio
Nationalis Historiae ac Philosophiae
ReIitutorum celeberrimo
Summis honoribus undaqueque aucto
Antonius filius mar. p.
MDCCXXX. Aet. LXVIII. Mens. VIII.

The filial piety of the younger Vallisneri accomplished a 
more laudable memorial for his distinguished parent, in a com-
plete and splendid edition of all his works, making three 
folio volumes, printed at Venice in 1733, and illustrated 
with plates, in one of which the fructification of the Lenna 
is exhibited. These writings, being frequently in the form 
of letters, are diffuse, but the Italian style of the author is 
esteemed by his countrymen. The whole work might be 
epitomized with advantage, and would be found rich in 
originality and acuteness. An ample life of Vallisneri is 
 prefixed to this publication, from whence we have extracted 
the above account. He is certainly entitled to rank with 
Redi, Malpighi, Reaumur, and Swammerdam, as an origi-
nal observer of the intricate and obscure physiology of 
infests, and the lower tribes of the animal kingdom. He 
co-operated with those philosophers in clearing away the 
theory of equivocal generation, and other rubbish of the 
schools. In medicine his merit is of a very high order, and 
his name marks an epocha in the history of that science in 
Italy. Those who had so long flumed over the mazy 
follies of ancient lore, were by him turned unwares out of 
their dormitories and easy chairs, before they had time to 
awake, much less to defend their pofts. He exalted the 
science from the study of books, to that of nature, and 
succes was the natural refult. In practice he had the good 
fortune to promote the use of the Peruvian Bark, which, at 
that period, had much prejudice to contend with. His prefi-
ptions were generally simple, and all his inquiries were free 
from credulity and prejudice. We cannot here enumerate 
the titles of all his various pieces. What relates to the 
theory of generation is most elccmled; and he had the cour-
age to oppose the then famous vermicular hypothesis of 
Leeuwenhoek. The memory of Vallisneri has been pre-
served by his countryman Micheli, in the name of a very 
curious and interesting genus of plants. See the next 
article.

VALLISNERIA, in Botany, was dedicated by Micheli, 
to the honour of his distinguished countryman, of whom we 
have given an account in the preceding article. No genus 
could have been more fortunately selected, as its history is 
now, in the writings of Linnaeus, identified with that of the 
generation of plants; of the theory of which, as taught by 
that illustrious botanist, it affords one of the most conven-t 
and celebrated proofs. Yet Micheli was ignorant of this 
striking fact; and has absolutely, as we shall find, described 
the two sexes as distinct genera. The male plant is his 
Vallisneroides. We can offer no apology for this oversight 
of so faithful an observer, but his attachment to Tourne-
fort, who shcut his eyes against the sexual doctrine, and 
Micheli durst not take the liberty of opening his own.—Mich. 
t. 10.—Clas and order, Dictea Dianidea. Nat. Ord. 

deep, oblong, often cloven, reflexed segments, including a 
conical, compressed Common Spadix, covered all over with 
several flowers forming a spike. Cor. of one petal, in three 
deep, obovate, widely spreading, or reflexed, segments, 
without a tube. Stam. Filaments two, erect, the length of 
the corolla; anthers roundish, simple.

Female, on a different plant, Cal. Sheath of one leaf, 
single-flowered, cylindrical, elongated, with two erect seg-
ments at the extremity. Perianth superior, in three deep, 
ovate, equal, spreading segments. Cor. of one petal, in three 
deep, linear, abrupt segments, shorter than the calyx. 
Pfiff. German inferior, cylindrical, longer than the seath; 
flyle very short; stigma in three deep, oval, convex seg-
ments, downy on the upper side, cloven half way down, 
rather longer than the calyx, and bearing at the back a 
small oblong appendage. Peric. Capsule cylindrical, of 
one cell, not burring. Seeds numerous, ovate, inserted in 
many rows into the sides of the capsule.

Eff. Ch. Male, Sheath in two deep segments. Spadix 
covered with flowers. Corolla in three deep segments.

Female,
V A L

Female, Sheath divided, single-flowered. Perianth in three deep segments, superior. Corolla in three deep linear segments. Stigmas three, cloven. Capsule cylindrical, of one cell, with many seeds.

Off. Such is the original genus, of which Micheli's figure is clearer than his description. There can be no doubt that the part marked A, B, in the middle of his plate, below, represents the under side of the three stigmas. Linneus, who never saw a living flower, mistook this point; but has corrected himself in manuscript. We have profit of this, and partly of Mr. Brown's definition. V. oellandra of Roxburgh, if it be thought the same genus, must lead to some further correction of the generic characters.

1. V. spiralis. Spiral Vallisneria. Linn. Sp. Pl. 1441. Willd. n. 1. Brown n. 1. (V. palustris, alge folio, italica, folis in fumitate denticulatis, flore purpureo; Mich. Gen. 12. t. 10. f. 1, female. Vallisoroides palustris, algio folio, italicum, folis in fumitate tenuiffime denticulatis, floribus albis, six confecipuis; Mich. Gen. 13. t. 10. f. 2, male.)—Stalk of the female flower spiral. Leaves flowering, linear, obtuse, finely serrated at the summit; tapering at the base.—In ditches in Italy, especially near Pisa. Communicated from near Arles, in Provence, by the late Dr. Broussonet, in 1781. Mr. Brown found, what he is almost certain of being the same species, in New South Wales, about Port Jackson. This plant is perennial, flowering in summer and autumn. The root consists of long fibres, and propagates itself very widely by runners, so that the canals, in which the Vallisneria grows, are choked up with its foliage, and rendered not navigable for boats. Stem none. Leaves all radical, very long, linear, falcated, pellucid, ribbed, smooth, entire, except at the end. Stalks of the female flowers very long, thread-shaped, unbranched, naked, fingle-flowered, curiously spiral, but becoming more or less straight when the flower is ready to open, by which means the latter floats on the surface, and after impregnation, the stalk coils up again, and lodges the fruit at the bottom of the water. This fruit is three or four inches long, and judged by Mr. Brown to be rather of the nature of a berry than a capsule. The male flowers grow on a separate plant, on short, simple, straight, radical stalks. Each minute white flower separates from the common fadice, and rises closed, like a little bubble, to the surface of the water. Burbling there, these flowers float about in immense numbers, covering the water, and impregnating the females above described. Micheli has faithfully described the economy of this interesting plant, though blind to its physiology.

2. V. americana. American Vallisneria. Michaux Borcl.-Amer. v. 2. 220. Willd. n. 2. Pursh n. 1.—"Stalk of the female flower nearly straight. Leaves erect, linear."—At the bottom of muddy and slow rivers in North America, flowering from Augslit to October. Michaux observed it in the Mississippi and St. John's rivers, Florida; Pursh in the Delaware, near Philadelphia, and elsewhere. The latter doubts whether it be a distinct species from V. spiralis; for he found the stalks of the female flowers to be, in deep water, really spiral. Michaux remarks, that the leaves are erect, less elongated than in the foregoing, and not tapering at the base. These circumstances may all be owing to the shallowwells and stillness of the water.

VALMASEDA, a town of Spain, in the province of Bilbao; 13 miles S.W. of Bilbao.

VALMIKI, in Biography, the name of a very celebrated Hindu poet, the author of that extraordinary poem in the Sanscrit language, entitled Ramayana, under which word we have given some account of its contents. Sir William Jones, in his ninth annivary discourse to the Asiatic Society of Calcutta, delivered February 1792, gives his opinion that the Cufh of Moses and Valmiki were the same personage. (See Ramayana and Triveni.) But we are not in possession of any biographical particulars respecting him. His great work, the Ramayana, is esteemed the earliest epic poem, and is cited as nearly equal in authority with the most sacred of the Hindoo books, such as the Purana and Veda, ascribed to Vyasa. See these articles.

VALMONT, de Bomare, James Christopher, was born at Rouen, in September, 1731. He was intended for the bar, but his inclination to natural history induced him to devote himself entirely to that pursuit, and having obtained an order from the duke d'Argenfon, the minister at war, to travel for the improvement of science, with sufficient funds for the purpose, he spent several years in visiting the principal cities of Europe, and examining the most famous collections engaged in natural history. Mines and metallic establishment engaged his particular attention; having visited Lapland and Iceland, he described its volcanoes; and returned, with many curious objects, to Paris in July 1756. He then began a course of lectures on natural history, which were continued till the year 1786. These lectures contributed to establish his reputation, and he had many advantageous offers from the courts of Russia and Portugal, the acceptance of which he declined. His works are as follow: viz. "Catalogue d'un Cabinet d'Histoire Naturelle," 1758, 12mo.; "Extraits Nomenclature du Systeme complet de Mineralogie," 1779, 12mo.; and "Nouvelle Expedition du Regne Mineral," 1761, 1762, 2 vols. 8vo. But his capital work was his "Dictionnaire raisonne Universel d'Histoire Naturelle," in 6 vols. 8vo. This has passed through several editions in 8vo. and 4to., and being the first of its kind, served as the basis of all the dictionaries of natural history that have appeared since that time. One of the latest editions appeared at Lyons in 1800, 15 vols. 8vo. This celebrated naturalist died at Paris, in August, 1807. Gen. Bioog.

VALMONT, or Valmont, in Geography, a town of France, in the department of the Lower Seine; 6 miles E. of Fécamp.

VALMONTONE, a town of the Popedom, in the Campagna di Roma; 6 miles S. of Palestrina.

VALNDORF, a town of Hungary; 5 miles S.W. of Szeben.

VALOE, an island of Sweden, in the bay of Chrlitiania; 7 miles S.S.E. of Tonberg.

VALOGNES, a town of France, and principal place of a district, in the department of the Channel. In 1546, it was pillaged by the English; 7½ petty N. of Coutances. N. lat. 49° 31'; E. long. 1° 23'.

VALOIS, Henry de, or VALESIUS, in Biography, born at Paris in 1603, and educated in the Jefuits' school, was admitted an advocate of the parliment of Paris, after having previously studied the civil law at Bourges. Declining the profection of the law, he devoted himself to literature, and particularly to the study of Greek and Latin authors. The affability of his application impaired his flight, the imperfection of which was in some degree counterbalanced by the retentiveness of his memory. Besides some private pensions which were granted him, he was appointed, in 1660, historiographer of France, with a considerable salary. At the age of sixty-one he married a lady, by whom he had seven children; and died in 1716, at the age of seventy-three years. His temper was hard and irritable; fond of praise, and sparing in bestowing it on others; impatient and querulous under bodily indigitation, but unfailing to the sufferings of others. With many infirmities and failings, he was a learned, discriminating, and accurate critic. His principal publications were, an edition of the "Ecclesiastical History of Eusebius," with a Latin version and notes; the "Ecclesiastical Histories of Socrates and Sozomen," as well as of "Theodoret and Evagrius," a valuable edition of "Ammiannus Marcellinus;" "Remarks upon Harpocrasin;" "Exposition Lib. V.;" with other pieces, printed after his death at Amsterdam, in 1740, under the care of Peter Burman. Moreri.

VALOIS, Adrian de, brother of the preceding, was born at Paris in 1607, and studied in the Jefuits' college. Although he acquired a competent knowledge of the Greek and Latin languages, he attached himself principally to the study of French history; and in 1646 appeared the first volume of his "Gesta Francorum," which was followed by two more in 1658. He began with the reign of the emperor Valerian, and traced the history of the Franks to the deposition of Childeric; and his work was generally admired. As a recom pense, he was associated with his brother in the office of historiographer, and in the pension annexed to it. In 1675 he published "Notissae Gallorum," fol, comprising, in alphabetical order, an account of the geography, towns, monasteries, &c. of France, deduced from its early records and histories. He followed the example of his brother, with whom he lived on terms of intimate union, by marrying a young wife, who brought him two children. He published, besides the works already mentioned, an edition of two poems written in the middle ages, a second edition of his brother's "Ammianus Marcellinus," and some other pieces relating to antiquities. He died in 1692, at the age of eighty-five years. His son, CHARLES de VALOIS DE LA MARRE, was also a man of letters, and became a member of the Academy of Inferences and Belles Lettres, and antiquary to the king. He published a collection of critical, historical, and moral reflections, and Latin poems under the title of "Valerian," and edited two poetical works of Vaillant the medallist, and wrote several papers for the Academy, of which he was a member. He died in 1747, aged seventy-six. Moreri.

VALOMBRESO gives its name to a congregation of Benedictine monks, founded in the Apenines by Guisbert of Florence, in the 11th century; who, in a short space of time, propagated their discipline in several parts of Italy.

VALORSINE, in Geography, a town of France, in the department of the Leman; 15 miles S.E. of Notre Dame d'Abondance.

VALOKE, a town of European Turkey, in Moldavia; 52 miles N. of Jassy.

VALPARAYSO, a town of Spain, in New Castile; 15 miles S. of Huete.

VALPARAYSO, a sea-port town of Chili, situated on a bay of the South Pacific ocean. This town was at first very mean, confisting only of a few warehouses, built by the inhabitants of St. Jago, for laying up their goods till shipped off for Callao, the harbour of Valparayo being the nearest port of that city, from which it is only 60 miles distant. The only inhabitants at that time were the few servants left by their respective masters for taking care of the warehouses, and managing their mercantile affairs. But in process of time, the merchants themselves, together with several other families, removed from St. Jago, in order to be more conveniently situated for trade; hence which it has gradually increased, so that at present it is both large and populous; and would be still larger, were it not for its inconvenient situation, standing so near the foot of a mountain, that a great part of the houses are built on its acclivity, or in its breaches. Valparayo, besides its parish-church, has a convent of Franciscans, and another of Augustines; but very few religious, and the churches belonging to them small and mean. It is inhabited by families of Spaniards, and calls both of Mulattoes and Mestizos. Here is a military governor nominated by the king, who having the command of the garrisons in the several ports, and of the militia of the place and its dependencies, is to take care that they are properly disciplined. The proximity of this port to St. Jago, has drawn hither all the commerce formerly carried on at that city. To this it owes its foundation, increase, and present prosperity. All the Callao ships which carry on the commerce between the two kingdoms come hither. In this port they take in wheat, tallow, cordovan-leather, corn, and dried fruits, and with these return to Callao; and a ship has been known to make three voyages in one summer between November and June. Valparayo is abundantly supplied with provisions from St. Jago and other places in its neighbourhood. Among the several kinds of game there is here such a plenty of partridges in their teason, which begins at March and lasts several succeeding months, that the muleteers knock them down with flocks, without going out of the road, and bring great numbers of them to Valparayo. But few of these or any other birds are seen near the town. It is the fame with regard to fish, very little being to be caught either in the harbour or along the coast, in comparison of what may be taken in the other parts. The harbour is everywhere where free from rocks and floods, except to the north-east of the breach De los Angelos, where, about a cable's length or two from the land, is a rock, which must be more carefully avoided, as it never appears above water, but sometimes has not a depth sufficient for a ship of any burden to pass over it; 225 miles N. of Conception. S. lat. 33° 5', W. long. 72° 16'.

VALPERGA, a town of France, in the department of the Dora; 11 miles S.S.W. of Ivrea.

VALPERSCHWEIL, a town of Switzerland, in the canton of Berne; 10 miles N.W. of Berne.

VALPO. See Walpo.

VALSALVA, Anton-Maria, in Biography, an eminent anatomist, physician, and surgeon, was born in 1666, at Imola, in Romagna. Having received the first elements of literature in the Jesuits' seminary, he was sent to the university of Bologna, and placed under the immediate tuition of the celebrated Malpighi, and here he pursued his various studies with an avidity which impaired his health. He graduated at Bologna in 1687, and connecting surgery with physic, acquired high reputation. He simplified and improved surgical instruments, banished from Bologna the cruel practice of cauterizing the arteries after amputation, and in the cure of deafness employed manual operations. In 1697 he was chosen professor of anatomy in the university, and appropriate buildings were erected for his use at the anatomical theatre. The school of Bologna acquired celebrity under his direction, and some of his pupils became eminent in their profession. Of this number was Morgagni. In advanced years Valsalva grew corpulent and lethargic, and was carried off by an apoplectic stroke in February 1723, at the age of fifty-seven years; leaving a widow and three daughters. His anatomical museum was bequeathed to the Institute of Bologna, and his various apparatus of chirurgical instruments to the hospital for incurables. The principal of his works is a treatise "De Aure Humana," reprinted at Bologna in 1704, 4to. and again with Morgagni's Epitaphes, at Venice, 1740. After his death, Morgagni published three of his "Differentialia" on anatomical subjects, which had been read before the Institute. This great anatomist's work "De Sedibus et Causis Morborum," contains a number of dissections by Valsalva. Morgagni Vit. Valsalv. Haller. Gen. Biog.

VALSECA, in Geography, a town of Spain, in Old Castile; 11 miles N. of Segovia.

VALSTAGNO, a town of Italy, in the Vicentin; 18 miles N. of Vicentin.

VALTANAS, a town of Spain, in the province of Leon; 15 miles E. of Valencia.

VALTELINE, a lordship of Italy, at the foot of the Alps; bounded on the N. by the Grisons, on the E. by the county of Bormio and the Breffan, on the S. by the Bergamasco and the Milanese, and on the W. by the county of Chiavenna and the Milanese. This country, which is called by the Grisons Veltin, or Veilin, and by the inhabitants Valle Tellina, is a valley inclosed between two chains of lofty mountains, about fifty miles in length, and from eight to twenty in breadth. It is exceedingly fruitful, and throughout its whole extent watered by the Adda, which, after receiving all the streams issuing from the forest, discharges itself into the Como lake. In some parts the heat is intense, but in others more moderate, and on the hills and the greatest part of the adjacent valleys the air is moistly cool. Of this variation in its temperature, the necessary consequence is a variation in the products of the earth. The levels in this valley, through which the Adda pursues its course, and the breadth of which in some parts...
is not less than a mile, exhibit a delightful variety of corn-fields, meadows, vineyards, and orchards of chestnuts and other fruits. The vineyards on the mountains towards the north produce the best wine in the whole country, and above them are corn-fields, meadows, and pasture-lands. The hills on the south side are covered with fine woods of chestnuts, fields, meadows, and rich pastures, in which graze numerous herds of cattle. This country abounds also in excellent red wine, of a most delicious flavour, and of so good a body that it will keep for a whole century, improving both in taste and wholesomeness, and gradually turning paler, till at length its redness totally disappears. Great quantities of this wine are exported. The apples and pears in moat places are not much esteemed; but the peaches, apricots, figs, and melons, are exquisite. Here is likewise plenty of lemons, citrons, almonds, pomegranates, chestnuts, and other delicious fruits. Its soil also would produce all kinds of grain andpulse; but the levels being interpenetrated with swampy places, which have hitherto remained without culture, and the vine-trade chiefly engrossing the attention of the inhabitants, it does not yield a sufficiency for their consumption without importation. Some parts grow hemp, and in the levels, particularly on the higher grounds and the mountains, the wine pastures. Bees and flilk-worms are bred here in vast numbers. The Adda yields plenty of fish, and is noted for its trout, which often weigh from fifty to sixty pounds. The whole of their mine-works here confine in a few iron-founderies.

The chief commerce of the Valteline is carried on with Milan and the Grifons. The principal exports are wine and flilk, which turn the balance of trade in its favour; they enable the inhabitants to exist without any manufactures, and help to supply the money which is exacted by the governors.

The wine is sent into the Grifons, Germany, the Venetian states, Bormio, and occasionally to Milan. Upon a rough calculation, 73,000 foms, or horse-loads, are annually exported. The flilk is sent to England, Zurich, and Baffe. The district of Delebio and Talomara produces the finest flilk, the neighbourhood of Sondrio the next in quality, and the district of Tirano supplies an inferior fort. Three thousand pounds of the finest fort, which is esteemed as good as the flilk procured from Piedmont, is sent annually to England by way of Oland. The greater part is wound in the Valteline, for which purpose there are flilk-mills in the principal districts.

Besides these commodities, the Valteline exports planks, cheese, butter, and cattle. The inhabitants receive from Milan, corn, rice, salt, filken fluffs; from Germany and Switzerland, cloth and linnen; from Genoa, spices, coffee, and sugar.

There are no manufactures in the Valteline, and almost all the menial trades are exercised by foreigners.

The population of the Valteline may be estimated from the following rough sketch:—

The cottages of the peafants, which are built of stone, are large, but gloomy, generally without glass windows; and exhibit an uniform appearance of filth and poverty.

Perhaps no part of Europe is more fruitful than the Valteline, and yet there is no country in which the people are more wretched. Many reasons may be assigned for the misery to which they are reduced. The first and principal cause is the form of government. The governors generally abuse the exorbitant authority entrusted to them by the laws; the peafants are imprisoned upon the slightest information; and as all transgressions are punished by fines, an accused person is seldom acquitted; so that a considerable number are annually ruined in the courts of justice.

Befide the individuals who are suppofed to suffer for their own guilt, the parishes are subject to continual affiffions, towards defraying the expenses for the trial and imprison-ment of the poor parishioners: if they are unable to pay the sum required, it is demanded from the parish to which the criminal belongs. In this cafe it frequently happens, that the affiffions, instead of being laid upon the landholders, are imposed upon each hearth, by which means the chief burden falls upon the poor.

Another cause of wretchedness proceeds from the present state of property. Few of the peafants are landholders; as, from the continual expropriation with which the people have groaned for above two centuries, the freeolds have gradually fallen into the hands of the nobles and Grifons, the latter of whom are suppofed to pollife half the elastic in the Valteline. The tenants who take farms do not pay their rent in money, but in kind: a sort of general poverty. The peafant defrays the costs of cultivation, and delivers nearly half the produce to the landholder; the re-maining portion would ill compensate his labour and ex- pense, if he was not in fome meafure befriended by the fertility of the foil. The ground feldom lies fallow, and the richerts of the valley produce two crops; the first is wheat, rye, or fpelt, half of which is delivered to the proprietor; the fcond is generally millet, buck-wheat, maize, or Turkey corn, which is the principal nourishment of the common people: the chief part of this crop belongs to the peafant, and enables him in a plentiful year to support his family with some degree of comfort. Thofe who inhabit the districts which yield wine are the moft wretched; for the trouble and charge of rearing vines, of gathering and pressing the grapes, it is often found in the cottages that they are fo apt to confume the flare of liquor allotted to them, in in-toxication, that, were it not for the grain intermixed with the vines, they and their families would be left almost deftitute of subsistence.

Befide the bufines of agriculture, some of the peafants attend to the cultivation of flilk; they receive the eggs from the landholder, rear the flilk-worms, and are entitled to half the flilk. This employment is not unprofitable; for although the rearing of the flilk-worms is attended with much trouble, and requires great caution; yet as the occupation is generally entrusted to the women, it does not take the men from their labour. With all the advantages, how- ever, derived from the fertility of the foil, and the variety of its productions, the peafants cannot, without the utmost difficulty, and contant exertion, maintain their families; and are always reduced to the general diftrefts, whenever the feafon is unfavourable to agriculture.

To these caufes of penury among the lower classes, may be added the natural indolence of the people, and their tendency to superflition, which takes them from their labour.

This country is without so much as one city, but has some considerable towns, with many thriving villages. Its language is a corrupt kind of Italian. The Roman Catholic is the only religion. Their clergy are under the jurif-diotion...
Valtelline.

...ction of the bishop of Como. They are not responsible to the ordinary courts, their immunities being so exorbitant as to render them almost independent of the civil authority; they are only amenable to the court of the bishop of Como. If a priest is guilty of any misdemeanor, his person cannot be secured without the concurrence of the bishop and governor of the district in which the crime was committed. It is therefore extremely difficult to bring an ecclesiastical to justice; as impunity is easily purchased, either by fearing the favour of the bishop's vicar or of the magistrate. Nor are these permissive privileges confined merely to the clergy, but extend to all persons wearing an ecclesiastical dress, with the permission of the bishop of Como.

All civil causes of the clergy, below the value of two hundred livres, are decided by the vicar of the bishop of Como; above that sum, they are brought before the bishop. An appeal from his decision lies to the pope's nuncio at Lucern, from him to the ecclesiastical tribunal at Aquilea, and from thence to Rome.

The whole country is divided into three districts or terzeros, called Sopra, Mezzo, and Sotto, or Upper, Middle, and Lower. Tirano is the capital of the first, Sondrio of the second, and Morbegno of the last. It is divided into five provinces, viz. those of the upper district; of the middle district, called Alto the government of Sondrio; of Teglio, of Morbegno, and of Traona.

Each of these five governments is subject to a magistrate appointed by the Grifons, who has changed every two years. The magistrate over the middle district is called governor of the Valtelline, and possesses in some respect a superior degree of authority to the others, who are styled podestias; he is also captain-general of the Valtelline.

All public concerns, which do not fall under the jurisdiction of the Grifons, are dissipated and determined by a council composed of five representatives, one from each district, which meets as occasion requires at Sondrio.

The Valtelline, together with the counties of Chiavenna and Bormio, (which had long been the constant source of hostility between the bishops of Como and Coire,) came, in the year 1356, under the dominions of Azzo Vificonti, sovereign of Milan, who quietly transferred them to his successors. Upon the death of John Vificonti, one of Azzo's successors, his territories were divided between his nephews Galeazzo and Barnabas. Upon the demise of Galeazzo, his son, John Galeazzo, secured the person of his uncle Barnabas, and having confined him in the castle of Trevio, until his death, which happened in 1395, annexed his dominions to his own, and became by this union, the greatest and most powerful prince in Italy. Maltino, son of Barnabas, took shelter, upon his father's imprudence, with Hartman, bishop of Coire, and died in exile, without recovering any share of his inheritance. Previous to his death, he formally ceded all his right and title over the Valtelline, Chiavenna, and Bormio, to the bishop of Coire, as a mark of gratitude for his protection. To this cession, at that time, of no avail, the Grifons owe the possession of these provinces. The claim lay dormant for above half a century, until some discontent arising in the Valtelline, in 1487, the Grifons made an irruption into that country, in support of the bishop's rights, but their arms not being at that time attended with success, they purchased a peace by renouncing all pretensions to the Valtelline. They renewed, however, their claim in 1512, when Ludovico, called the Moor, duke of Milan, was taken prisoner by Louis XII.; and the whole Milanese, comprising the Valtelline, occupied by that monarch. Upon this revolution, the Grifons, in conjunction with the bishop of Coire, entered the Valtelline, and having expelled the French troops, took possession of the country; they were received with joy by the inhabitants, who did homage to their new sovereigns, and in return obtained from them the confirmation of all their privileges. A compromise was immediately entered into between the bishop of Coire and the three leagues to share between them the sovereignty of this country. In the following year, Maximilian Sforza, raised to the ducal throne of Milan upon the expulsion of the French, ceded in perpetuity the possession of the Valtelline, Chiavenna, and Bormio, to the bishop of Coire, and the Grifons; and this cession was ratified by Francis I. in the treaty of peace which he concluded with the Swifs and their allies, the Grifons, in 1542, when he obtained possession of the Milanese. In 1530, the republic of the Grifons acquired the whole dominion of the Valtelline, to the exclusion of the bishop of Coire, under pretence that the latter had not fulfilled his quota of men and money in the war with James of Medicis, in defence of their ceded countries; accordingly they compelled the bishop to sell his share of the sovereignty over the Valtelline, Chiavenna, and Bormio, for a yearly income of 575 florins, to be paid to the bishop and his successors out of the customs of Chiavenna. From that period, those provinces were possessed by the Grifons without molestation, until the rival interests of France and Spain, the intrigues of the pope, religious enthusiasm, the zeal of party, and the actions of the Grifon governors, kindled an insurrection which commenced with a massacre of the Protestants, and raged for a series of years with the most savage and unremitting fury.

During the contest wars, which from the accession of Philip II. the relentless ambition of the Spanish court entailed upon Europe, the German and Spanish branches of the House of Austria were inseparably united; and the council of Vienna were directed by the cabinet of Madrid. Under these circumstances, the Valtelline, which, by connecting the Tyrol and the Milanese, afforded the only secure passage for the junction of the Austrian and Spanish troops, became of signal importance.

The same reasons which rendered the Spaniards desirous to secure the Valtelline, induced the French to obstruct their designs. The Spaniards, however, pursued their projects upon the Valtelline without opposition, when they were freed from their most formidable rival, the count of Fuentes, governor of Milan, by assassinations, and availed themselves of the domestic intestine of the Grifons and the inhabitants. When all the Protestants were either destroyed or driven out of the country, the remaining inhabitants re-equipped their allegiance to the Grifons, and framing a new form of government, threw themselves under the protection of the crown of Spain, which sent an army to their support. The people of Bormio followed the example of the Valtelline, with this difference, that they did not massacre, but only expelled the Protestants. Having entered into an offensive and defensive alliance with the inhabitants of the Valtelline, they also formed an independent commonwealth.

The Grifons, divided among themselves, were totally unequal to the chastisement of their resented subjects. The Catholics were desirous of employing the irritation of Spain, for the purpose of recovering the Valtelline; the Protestants, inclined to vigorous measures, proposed an application to the Swiss cantons, Venice, and France. A violent discussion, which were not terminated without bloodshed, the Protestant interest prevailed, and a deposition was sent to those powers.
When cardinal Richelieu acquired ascendency, and effected a revolution in the French politics, he perceived the importance of the Valteline, and adopted measures, which proved successful; so that in two campaigns the Spaniards were driven from the Valteline, Chiavenna, and Bormio. Under the administration of Richelieu, it was agreed, that the Valteline should again be restored to the Grifons, upon the following conditions: no other religion but the Roman Catholic to be tolerated; the inhabitants to elect their own governors and magistrates either from themselves or from the Grifons, but always from persons of the Roman Catholic persuasion; and the governors to be confirmed by the Grifons. In return for these privileges, it was stipulated that the inhabitants should pay an annual tribute, the amount of which was to be settled by mediation. In consequence of this treaty, concluded on the 5th of March 1626, the French restored the forts of the Valteline into the hands of the pope, and evacuated the country.

When Richelieu had completed the reduction of the Huguenots by the capture of Rochelle, he turned the whole force of France against the Hause of Austria; and among other enterprises, directed his attention to the Valteline, but the Grifons, encouraged and aided by the Spaniards, drove the French from the country; the treaty of Milan produced a close alliance between the Spaniards and the Grifons; and the Valteline was restored. This treaty, contracted in the year 1635, secured to the Spaniards the passage of the valley, which was the great object of the war, and restored the Valteline, Chiavenna, and Bormio, to the Grifons, under the following conditions: an act of oblivion; the immunities of the subject countries to be confirmed as they existed before the revolution of 1623; no religion but the Catholic to be tolerated; no person of any other persuasion to be permitted to reside, excepting the governors, during the two years they should continue in office, and the Protestants possessed of lands, who should not be allowed to remain in the country above three months in the year; the privileges of the ecclesiastics to be restored in their full latitude.

Since the pacification of 1677, no material change took place in the state of affairs. The sovereigns of Milan have always cultivated the friendship of the Grifons; and the inhabitants of the Valteline endured a regular course of tyranny under the government of a free state; confirming a fact notorious in the annals of ancient Greece, that no people are more opposed to the subjects of a democracy.

During the progress of the French revolution, Bonaparte confirmed the union of the revoluted provinces with the Cifalpine republic; so that after a period of nearly three centuries, the Valteline, Chiavenna, and Bormio, were again incorporated with the Milanese under a republican government; but the expulsion of the late French emperor has restored the ancient arrangements in Italy, and the Valteline returns to its former poifforers. Coxe's Switzerland, vol. iii.

VALERIE, LA, a town of Canada, on the St. Lawrence, N. lat. 45° 54'. W. long. 73° 17'.

VALTHURAND, or VALTHERAND, a town of Holland, in Overffeld; 12 miles N.E. of Covenrod.

VALTRIERA, a town of Spain, in Navarre. Near it is a mine of fal gom; 10 miles from Tudela.

VALVA, in Ancient Geography, a mountain of Africa, being one of the most considerable in Mauritania Caffariensis.

VALVA, in Geography, a town of Naples, in Abruzzo Citra, the see of a bishop; 18 miles S.S.W. of Civita di Chieti.
VALUATION OF LAND.

of the land, which is the ground-work of the calculation; though it has little weight in the scale of valuation. The fee-simple value of an acre of land may be less than twenty shillings, or it may be more than an hundred pounds. Nevertheless, it is on the quantity the rental value is calculated; and it is usual for the person who parts with it to exhibit a "particular" of the estate or property on its disposition; nothing, or which ought to be, not only the aggregate quantity, but the number of acres that each piece or parcel contains, as well as other matters; and ought, most particularly, to specify the distinct quantities of the lands of different qualities; in order that their several rental values may be ascertained with greater ease and accuracy.

2. The intrinsic quality of the land, which is essential in forming the estate. But even this, in a general view of the value of lands throughout the kingdom, is often, it is said, of secondary consideration: for, in many cases, their values are given by situation, rather than by soil and sublirata. In some cases, as has been seen, the value of the situation may be a great many times more than that of the intrinsic value of land. But this excessive influence of situation is, however, limited in its effects, and is chiefly confined to the environs of large towns, and other extraordinary markets for produce of the farm-kind. A great majority of the lands of this country owe their values less to situation than to intrinsic quality; and to come at this with sufficient accuracy, is the most requisite, and, at the same time, the most difficult part of valuation; as it depends almost wholly on extemporary judgment, exercised on the frequently few data which rife to the eye in passing over the field of estimation. It is, therefore, almost needless to state, that to acquire the degree of judgment which is necessary to the execution of this difficult critical task, it is required to know and be perfectly acquainted with the nature and produciveness of lands of different appearances: a sort of knowledge which scarcely any thing but mature practice in the cultivation and use of lands of different qualities can sufficiently teach; though long habit may do much in ordinary cases towards hitting off the value of lands, without an extensive knowledge of the practice of agriculture.

There are cases, however, it is said, in which both of these qualifications are found insufficient to give any accuracy of judgment, even among provincial valuers of land. And a person who ventures to step forward as an universal valuer, should have either an extraordinary talent for the purpose, or should, after a suitable imitation, have had great experience in rural concerns in different parts of the kingdom.

3. The situation; which, although it has been already stated, that the value of the lands of this country, aggregated, confidered, depends less on situation than on intrinsic quality, yet in every part it has great influence. Thus, an acre of land, the intrinsic quality of which renders it, in an ordinary situation, in what regards locality merely, worth twenty shillings the acre, would, not be, it is observed, in some districts or places, be worth more than fifteen shillings, while in others it would bear to be estimated at twenty-five shillings, or even a higher price of rent, to a farmer on a large scale, and away from the immediate environs of a town, or any populous district of manufacture; for reasons that will be seen in examining the different particulars of situation. In the temperature of situation too, whether it be given by elevation, aspect, or exposure, a powerful influence is found, which is capable of altering exceedingly the value of lands. The same sort of soil and subsoil, it is said, which is not unfrequently seen on exposed mountains, and hanging to the north, and which in that situation is not worth more than five shillings an acre, would, if situated in a sheltered vale or tract, and lying well to the sun, be worth twenty shillings, or a greater rent. Even on climature, something confiderable in this business, it is thought, depends. In the southern part of the country, the harvest is, in general, a month earlier than in those of the north; though it is not regulated exactly by the climate, or the latitude of the places: this is consequently a circumstance that requires to be attended to by those who ffinish the values of estates or lands. For an early harvest is not only advantageous in itself, but gives time to till the ground, or to take an autumnal crop, which are advantages that a late harvest will not do well admit of being bad. And another kind of temperature of situation has still, it is supposed, more influence on the value of lands, which is that of the moistness of the atmosphere. A moist situation not only gives an uncertain and often late harvest, but renders it difficult and hazardous; as is too frequently experienced on the western coast-sides of this island. Even in the turn of surface, exercise is found, it is said, for the judgment. Lands lying with too steep or too flat surfaces, particularly when of the arable kind, and retentive, are of less value than those which are greatly swelling, so as to give a sufficient discharge to surface-water, without their being difficult of cultivation. Steep-lying lands are not only troublesome and expensive under the operations of tillage, but in taking out manures, and getting off the produce. Lands lying with an easy descent, or on a gently billyow surface, may be worth more by many pounds an acre in the money they will bring, than others of the same intrinsic quality, hanging on a steep. Another consideration of the same weight in valuing an estate, or other landed property, is a supply or water for domestic purposes, for the uses of live-flock, and for the purpose of irrigation. There are situations, it is said, in which a copious stream of calcareous water would enhance the fee-simple value of a large estate some thousand pounds. Likewise a sufficient supply of manure, whether dung, lime, marl, or other fertilization, being at a moderate price, and within a moderate distance of land-carriage, materially adds to the intrinsic value of lands. And the established practice of management of the district or county in which an estate or land lies, is capable of enhancing or depressing the value of it exceedingly. Even the single practical point of ploughing light and loamy lands with two oxen, or two active horses, instead of four heavy oxen, is capable of making a difference, on good land which is kept alternately in herbage and corn-crops, of from five to ten shillings a year, on the acre; or ten pounds an acre in the money value which it is worth.

The price of labour is also rated as another regulator of the marketable value of land in a given district. It is always right, however, to compare this with the habits of exertion and industry which prevail among farm workmen, before the extent amount of labour can be safely set down. The price of living too, or expence of house-keeping, prevalent among farmers, has its share of influence on the value of lands. In the more reclusive parts of the north of this country, the farmers, especially of the lower and the more inferior classes, and their servants, are fed, clothed, and accommodated, at nearly half the expence of those of a similar degree in many parts of the more central and southern districts. In a county where frugality prevails too, lands of a given quality will ever, it is said, bear a higher rent than they will where a more profuse manner of living has gained a footing. Hence, likewise, the spirit of improvement, or the prejudice against it, which prevails in a district, is a circumstance of some value, it is supposed, in this intention. For
if the former be in a progressive state, especially if it be still in the more early stages of its advancement, a rapid increase of rent may, with a degree of certainty, be expected: whereas, under the lagging influence of the latter, half a century may, it is thought, pass away before the golden chariot of improvement can be profitably put in motion. And lastly, may be noticed, the attractive centre to which the labours of the husbandman will ever tend,—markets, in which, more than in any other circumstance, we are to look for the existing value of lands. Their influence is not confined to towns and populous places of manufacture, for in ports, and on quays, whether of inlets, estuaries, rivers, or canals, markets are met half way; even by good roads their distance from the farm-field may be faid to be shortened.

In this detail of the particulars of situation in respect to the value of landed property, it is observed, the attention requisite to be employed by a valuer is called up to act in a county that is new to him is perceived. A person, or even a professional valuer, who acts in a district, the existing value of the lands of which he is sufficiently acquainted with, determines at sight, and according to the best of his judgment, on their respective values: for he knows, or ought to know, their current prices; what fuch and such lands let for in that neighbourhood; what he and his neighbours give, or would give, for lands of the same quality and flate, without advertiing to the particular circumstances of the situation, they being considered and given as the established amounts arising out of them; refting his judgment solely on the intrinsic quality and existing flate of each field or parcel as it passes under his eye. But let his skill be what it may in a county or district in which he has acquired a habit of valuing lands, he will, in a distant part or district, the current market prices of the lands of which may be ten, twenty, or fifty per cent. above or below those which he has been accustomed to put upon lands of the same intrinsic qualities and existing stales, find himself at a loss; until he has the current prices of the place or county, or has well weighed and considered the circumstances of situation: to which, in every case, he must necessarily attend, before he can determine their value under an improved practice, or venture to lay down general rules for their improvement.

Another class of circumstances which influence the marketable value of lands still remains, it is faid, to be enumerated and considered. These relate to their existing state, or the manner in which they lie at the time. Their state in respect to inclosure is a matter of great consideration. Open lands, though wholly appropriated, and lying well together, are of much less value, except for a sheep-walk, or a rabbit-warren, than the same lands would be in a state of fituable inclosure. If they be disjointed and intermixed in a state of common field, or common meadow, their value may be reduced one-third. If the common fields or meadows be what is often termed Larnas land, and become common as soon as the crops are off, the depression of value may be let down at one-half of what they would be worth in well-fenced and incumbered with that ancient custom. The difference too in the value between lands which lie in a detached state, though within well-fenced inclosures, and those of the same quality that lie in a compact form, or, in the familiar phrase, within a ring-fence, is considerable. The disadvantages of a fattered estate are, it is said, similar to those of a fattered farm. Even the single point of a want of convenient access to detached fields and parcels is, on a farm, a serious evil. And it is on the value of farms that the value of an estate or land is to be calculated. The state of the roads, whether public or private, within an estate, and from it to the neighbouring markets, or places of delivery of produce, is further an object of consideration. And in this view, the state of the water-courses, or fewers and ditches, within and below an estate, likewise requires to be examin'd into; as the expense of improvement or reparation will be more or less, according to their existing state at the time; or, perhaps, by reason of natural caufes, or through the obli-viency of a neighbour, and the defcentiveness of the present laws of the country in this respect, the requisite improvements cannot be effected at any expense. The state of drainage of lands that lie out of the way of floods, or collected water, requires also to be taken into consideration. For although the art of draining is now pretty well underflood, it cannot be practised on a large scale, without much cost. The state of the lands too, as to tillage and manure, is attended to more regard than is generally bestowed on it, in valuing them. Even to a purchaser, and fift more to a tenant for a term, their state in these respects demands a share of attention. Lands that are in a high state of tillage and condition, so as to be able to throw out a succedence of full crops, may be worth five pounds of purchase-money an acre, more than those of the fame properties, which are exhausted by repeated crops, and lie in a undefiled state of fowls; from which they cannot be rai'd, but at a great expense of manure and tillage. Their state, as to grafts or arable, is, it is thought, better underflood, and generally more attended to. Lands in a state of profitable herbage, and which have lain long in that state, are not only valuable as bearing a high rent while they remain in that condition, but, after the herbage has begun to decline, will seldom fail to throw out a valuable succedence of corn-crops. Hence the length of time which lands, under valuation, have lain in a state of herbage, especially if it has been kept under paturage, is a matter of inquiry and estimation in the execution of business of this fort. And, lastly, the state of farm buildings and fences is, it is conceived, a thing of serious congratulation. Buildings, yards, and inclosures, that are much let down, and gone to decay for want of timely reparation, incur a very great expense to raise them again to their proper state. And when great accuracy of valuation is called for, as where the purchase value of an estate is left to reference, and when the tenants are not bound, or if bound are not able, to put them in the required state, it becomes requisite to estimate the expense which each farm, in that predication, will require to put it in sufficient repair, so as to bring the whole into a fituable state of occupation. This comes, however, more properly under the head of deductions, encumbrances, and outgoings, which are considered below. The same principle of valuation as the above holds good too in ordinary cases.

In speaking of encumbrances and deductions, it is said, that it appears, by a long leafe, that the fee-simple value of an estate may be in effect annihilated. Even a lease for lives, with a mere conventional rent, may reduce it to nearly one-third of its fee-simple value. And every other kind of lease, if the rent payable be not equal to the fair rent-lead value at the time of the disposable, is an encumbrance, even to a purchaser who has no other object in view than that of securing his property on land, and receiving interest in rent for the money laid out. If personal convenience be immediately wanted, or improvements required to be done, a lease, though the tenant pays a full rent, becomes an obfacle to the purchase, and is consequently to be considered in fixing the value. And an error, which is not unfrequently committed in estimating the encumbrance of a lease for
VALUATION OF LAND.

for a term of years, is here, it is said, to be noticed. The difference between the lease rent and the full rental value, encumbered with the same outgoings and repairs as the lease rent, being ascertained, it is multiplied by the number of years unexpired, and the product in full deducted from the value of the land, free from such encumbrance. But from the product, thus found, ought to be deducted half the interest thereof, during the said number of years, together with that of one half-year over, if the rent be payable half-yearly, or of one year, if payable annually. For all that a purchaser has a right to expect is to receive the full rent for his land, during the continuance of the lease. The tenant pays him what the lease stipulates; and if the seller were to make up the remainder, at the end of every six or twelve months, whenever the tenant is to pay his part, the purchaser would receive the full rent, the same as if no encumbrance had existed. But if the seller pay down the whole sum in ready money, at the time of the sale, which in effect he does, he is certainly entitled to some discount for prompt payment. Thus, supposing the difference of rent, occasioned by the lease, to be ten pounds a year, and the length of the term to run to be ten years, the product would be one hundred pounds. And supposing, for the sake of calculation, the stipulated payments to be annual, the interest to be deducted would be the half of fifty pounds, (the interest of one hundred pounds for ten years, at 5 per cent.) with the half of five pounds (one year's interest), together amounting to twenty-five pounds ten shillings; which being deducted from one hundred pounds, the gross product, leaves seventy-two pounds ten shillings, the clear sum to be deducted. And the truth of this rule of calculation may, it is thought, be familiarly proved: for if the seller were only to pay the deficiency of rent, as it should become due, he would, during the first year, hold the whole hundred pounds in his hands, the interest of which, at 5 per cent., is 5l.

The first year (as above) he would hold £ 100 £ 5 0 0
The second ditto 90 4 10 0
The third ditto 80 4 0 0
The fourth ditto 70 3 10 0
The fifth ditto 60 3 0 0
The sixth ditto 50 2 10 0
The seventh ditto 40 2 0 0
The eighth ditto 30 1 10 0
The ninth ditto 20 1 0 0
The tenth ditto 10 0 1 0

27 10 0

In respect to tithes, where in valuing lands they are considered as tithe-free, the tithe or modus, if any, requires to be deducted, as an encumbrance; and from the great variation in the values of tithes and modules, according to cultum, and plans of occupation, it is the plainest way of proceeding to value all lands as free of tithe, and afterwards to make an allowance for whatever they may be estimated to be worth. In regard to taxes, too, although it may be called the custom of the country for proprietors to pay the land-tax, and the occupier all the other taxes; yet this is not the universal practice; nor is it, in valuing an estate on sale, and to be let at will, a matter to be inquired into. The annual amount of payable taxes, and other outgoings, are the facts to be ascertained: for whoever discharges them, they come as a burden upon the gross value of the lands, out of which they are payable. For if a tenant pay them, his rent is, or ought to be, ascertained and fixed accordingly. But

Vol. XXXVI.

if an estate on sale is already let under lease, for a term to come, it is highly requisite to ascertain what parts of the annual outgoings and repairs are discharged by the tenants, and what the proprietor will be liable to, during the term to run. The land-tax, where it still exists, is extremely uncertain as to its value; and the poor-tax is equally varying in different situations. The church, highways, and county rates are, taking them on a par of years, left liable to local uncertainty, and are consequently left entitled to inquiry by a value of lands. And the fixed payments, or rent charges, such as chief rents, quit-rents, annuities, endowments, schoolmasters' salaries, charitable donations, and others of the same kind, to which an estate is liable; also repairs of public works, buildings, roads, &c. incumbent on the estate, are subjects of inquiry and estimation; as well as the ordinary repairs. Further, too, the hazard or risk under valuation, as that of their being liable to be inundated in summer, or to be torn away by floods at any season, is entitled to mature consideration. For although these evils may generally be remedied by river-breaks and embankments, the erecting of them is mostly attended with great expense; and the estimated value of this becomes, in course, a fair deduction to be considered by the land-value. It is noticed that there are two practical methods of valuation, with respect to taxes and other outgoings, as in regard to tithes; namely, either to set down the gross value of the lands, and then to deduct the outgoings; or to view them under their encumbrances, and to estimate in a summary way their next rental value. The latter is the more general, but the less accurate, manner of performing the business.

This, it is said, is what relates to the purchase value of the lands, but that, appurtenant to an extensive estate, there are generally other valuable considerations; as minerals and foils, whether metals, fuels, calcareousities, or groffer earths; waters, whether they are valuable for fisheries, decoys, mills, domestic uses, or the irrigation of lands; and timber, as of woods and hedge-rows. Buildings, too, that are not let with the farms, but which bear rent, independent of the lands; which, when scattered over an estate, may well be considered as belonging to landed property. To these may be added, the estimated value of evident improvements; and, lastly, the abstract rights which arise out of appropriated lands, or their appurtenances, as the right of commonage, which is generally of some value, even when commons lie open, and may be of more, when they shall be enclosed; provided the cost of enclosure do not turn out to be more than the extra value of the appropriated lands, above which naturally or fortuitously attends the lands of the common right in their open state. The right of seigniority to fee-farm rents, or other chief rents, payable to the possessor of lands on sale out of the lands of other proprietors. These rents, though small, are of certain value in themselves; and the idea of superiority, which they convey to the minds of some, may be worth more than the pecuniary value; which indeed, where the farms are very small, as is often the case, is much lowered by the expense of collecting them. The rights of foundlands, or manorial rights, are at present, if not in their origin, very different from those last mentioned; and the value of which is to be estimated by the quit-rents, fines, heriots, echeats, and amereacements, which long cultum and a train of circumstances have attached to the given court. And beside what relates to the appropriated lands of the manor, the lord has a profit arising from the commonable lands, if any lie within it, as lord of the foill which cannot be broken without his permission; hence the minerals and foils which it covers belong to him, as well as the timber which grows upon the waft, and the
VAL

waters that are connected with it. Moreover, in ordinary cases, he is lord of the game which inhabits or frays upon his manor. This being, however, a right of pleasure rather than profit, has no fixed standard of estimation. The right of tithe, when attached to an estate, is the most defirable of abstract rights arising out of landed property. For as far as the right extends, whether to a lay rectory or a vicarial improprietary, the lands which it covers becomes in effect tithe-free; as every judicious proprietor incorporates the rents of the tithe with those of the lands out of which it is payable; thus, if the right, as it generally is, be rectorial, freeing them wholly from the encumbrance of tithes, as a tax on improvements, and as an obstacle to the growth of grain. The right of advowson, or the privilege of appointing a pastor to propagate religion and morality upon an estate, properly enough belongs to its owner; as no other individual is so intimately concerned in the moral conduct of its inhabitants. The right of representation, or election, or the appointment, in whole or in part, of a legislator to assist in promoting good order in the nation at large. And when classes of the community, it is asked, can produce a fairer claim to this right than the proprietors of the country? The value of these rights is left to others to estimate and determine. See Timber and Tithes.

The chief circumstances to be considered having thus been pointed out, and their importance and influence explained, in concluding the subject it may be observed, that the difference between the particulars that give value to a landed estate, and the encumbrances to which it is liable, is the net value of the property under valuation.

VALUE, Valor, in Commerce, the price or worth of any thing.

VALUE, Intrinsic, denotes the proper, real, and effective worth of any thing; and is chiefly used with regard to money: the popular value of which may be raised and lowered at the pleasure of the prince; but its real or intrinsic value, depending wholly on its weight and fineness, is not at all affected by the stamp or impression thereon. It is generally on the foot of this intrinsic value, that specie is received in foreign countries; though in the places where they are coined, and where the sovereign power makes them current, they sometimes pass for much more.

It is, in good measure, on the difference of those two values, one of which is, as it were, arbitrary, and the other, in some part, natural, that the difference of exchanges depends; and those still rising and falling, as the rate at which a specie is current, comes nearer or farther off the just price of the metal of which it consists.

VALUE, in Bills of Exchange, is used to signify the nature of the thing, (as ready money, merchandizes, bills, debts, &c.) which is given, as it were, in exchange for the sum specified in the bill.

From four different manners of expressing this value, some distinguished four kinds of bills of exchange. The first bears value received, simply and purely, which comprehends all kinds of value; the second, value received in money or merchandize; the third, value of mifliff; and the fourth, value underflood.

The first is dangerous, and the fourth but little used: accordingly, to have the value well expressed, and to prevent the ill consequences of overights therein, it is well provided by the French ordinance of 1673, that bills of exchange should contain the name of the person to whom the contained sum is to be paid; the time of payment; the name of him who has given the value; and whether it was received in money, merchandize, or other effects.

VALUE, Valor, or Valenia, in Law. Well gives us a nice difference between value and price; the value (says he) of things in which offences are committed, is usually comprised in indictments; which seems necessary in theft, to make a difference from petty larceny; and in trespasses, to aggravate the fault and increase the fine.

But no price of things fere nature may be expressed, as of deers, hares, &c., if they be not in parks or warrens. And where the number of things taken is to be expressed in the indictment, as of young doves in a dove-house, there must be laid pretii, or ad valentiam: but of divers dead things, ad valentiam, and not pretii: of coin not current, it shall be laid pretii, but of coin current, neither pretii nor ad valentiam: the price and value being certain.

VALVE, Valvula, from valves, folding-doors, in Hydraulics, Pneumatics, &c. is a kind of lid, or cover, of a tube or vessel, fo contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture: so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits it to escape, and prevents its re-entrance. For water, those valves are the bell which intercept the passage least; and none appear to answer this purpose better than the common clack-valve of leather, which is generally with-in single, or divided into two parts; but it is sometimes composed of four parts, united so as to form a pyramid, nearly resembling the double and triple valves which are formed by nature in the hearts of animals. A board, or a round flat piece of metal, divided unequally by an axis on which it moves, makes also a very simple valve. Where a valve is intended for intercepting the passage of steam, it must be of metal: such a valve is generally a flat plate, with its edge ground somewhat concavely, and guided in its motion by a wire or pin. For air, valves are commonly made of oiled filk, supported by a perforated plate or grating.

Valves are of great use in the air-pump and other wind-engines; in which they are ordinarily made of pieces of bladder, or oiled filk.

In hydraulic engines, as the emboli of pumps, they are frequently of leather; the figure round; and they are fitted to shut the apertures of the barrels or pipes.

Sometimes they are made of two round pieces of leather, inclosed between two others of brass; having divers perforations, which are covered with another piece of brass, moveable upwards and downwards, on a kind of axis, which goes through the middle of them all.

Sometimes they are made of brass, covered over with leather, and furnished with a fine spring, which gives way upon a force applied against it: but, upon the ceasing of that, returns the valve over the aperture. (See Pomp.) See alfo for the construction of different sorts of valves for the buckets of pumps, Defagurers, Exp. Phil. vol. ii. p. 156, &c; and for the description of a new valve by M. Belidor, ibid. p. 156.

VALVE, in Anatomy. See Valvula.

Constantine Varolius, a Bolognec, and physician of Gregory XIII., who died in 1570, was the first that observed the valve in the colon. Bart. Eufhachio, a native of San Severno, in Italy, discovered about the same time the valve at the orifice of the coronary vein; and that remarkable one at the orifice of the lower trunk of the vena cava, near the right auricle of the heart: though he did not take it for a valve, but merely for a membrane.

Sig. Lancii, physician to pope Clement XI., who first published Eufhachio's works, takes the use of this valve to be, to prevent the blood of the upper vena cava from striking
striking with too much violence against that of the lower; and Mr. Winlow, who has confedered it very diligently in the Memoirs of the Royal Academy of Sciences, is much of the same opinion.

But as it gradually dwindles in children, and at length becomes quite lost in adults, still diminishing as the foramen ovale does, it should seem to have some other office, and that chiefly regarding the circulation of the blood in the fetus. See Circulation of the Blood, and Fetus.

Valve, in Gardening, the divided parts of a feed-veffel, or properly the external division of a dry feed-veffel, such as a capsule or pod; as in the pea, bean, vetch, and many others, which, when ripe, splits into two or more divisions, in order to throw out the contents, each of which divisions is denominated a valve. The valves of culinary vegetables are of several different kinds, according to the number of divisions, but principally of the univalve and bivalve kinds.

Valverde, of Val Verdes, in Geography. See Lca.

Valverde, a town of Spain, in New Castile; 20 miles S. of Salamanca.

Valverde del Camino, a town of Spain, in the province of Seville; 17 miles N.E. of Moguer.

Valverde de Friesno, a town of Spain, in the province of Leon, on the borders of Portugal; 24 miles N.N.W. of Curia.

Valuki, a town of Ruflia, in the government of Vorone; 108 miles S.S.W. of Voronez. Lat. 50° 2'; E. long. 37° 44'.

Valuntown, a town of the state of Connecticut; 10 miles N.N.E. of Norwich.

Valvula, valve, in Anatomy, a name given to various parts in the body. See Valve.

Valvula Cobi, or Hei, the valve placed at the communication of the large and small interlines. See Intestine.

Valvulae Convolventes, folds of the mucous membrane of the small intestine. See Intestine.

Valvulae Eutachii, Nothius, or Reticulata, a small fold at the entrance of the inferior vena cava into the right auricle. See Heart.

Valvula Magna Cerebri, or Vienosjoni, a part of the brain. See Brain.

Valvula Mitralis, the valve of the left auriculo-ventricular orifice of the heart. See Heart.

Valvula Seminacres, or Sigmoides, valves placed at the entrance of the aorta and pulmonary artery. See Heart.

Valvula Tricuspidales, or Triglachina; the valve of the right auriculo-ventricular opening of the heart. See Heart.

Valvulae Venarum, folds of the internal membrane of the veins, preventing the reflux of the blood. See Heart.

Vama, in Ancient Geography, one of the navigable rivers of India, which discharged itself into the Ganges. Pliny.—Allo, a town of Spain, in Beteria, belonging to the Beteri-Celtici. Ptolemy.

Vamana, in Mythology, a name or title of the Hindoo deity Vishnu. It means a dwarf; and was applied in consequence of an incarnation of Vishnu in this humble form. See next article.

Vamanavatara, one of the ten grand incarnations of Vishnu; called, by way of pre-emience, dasavatara, or the ten deities, to distinguish them from others of the same deity of less importance. As noticed under the article Vishnu, this manifestation was the fifth of the ten; but the first that occurred after the golden or virtuous age of the Hindoos. It was followed by a less virtuous age, in the course of which Mahabeli, a monarch reasonably virtuous, became so elated, that he omitted the essential ceremonies to the gods; and Vishnu, deeming it expedient to check the influence of such an example, resolved to punish the arrogant raja. He, therefore, condescended to become the son of Kalyapa and Aditi; and, as the younger brother of Indra, was incarnated in the person of a wretched Brahman dwarf. (See Indra and Kalyapa.) Appearing before the king, he allotted a boon; which being promised, he demanded as much as he could pace in three leaps. Nor would he deign farther, though urged by Beli to demand something more worthy of the donor.

Mahabeli, it would appear, had referred to some of these precesses; and the boon asked and yielded, was, as usual with mighty rajas, the sovereignty of the universe, which includes the three regions of the earth, heaven, and hell. To avert the effects of the abuse of this power, dangerous even to the gods, and to refuse their sovereignty, Vishnu referred to the artifice we are describing.

On obtaining the king's promise, the dwarf required a ratification of it; which was done, as is still practiced, by pouring water on the hand of the suppliant. This Beli proceeded to do, though warned of the consequences; learning not to ratify that for which his royal word would pledged.

As the water fell into his hand, the dwarf's form expanded till it filled the world; and Vishnu now manifesting himself, deprived Beli at two leaps of heaven and earth; but he being in some points a virtuous monarch, left Patala, or the lower regions, still in his dominion. (See Patala.)

In this character, Vishnu is sometimes called Trivikrama, or Trivikrama, meaning the three-leap-taker. Beli, as king of the infernal regions, seems to correspond with Yama; which see. Sir William Jones deemed this king the same with the Belus of western history. See Belus, and Mahabeli.

Writers of the sect of Vaishnava maintain, that the ratifying stream poured on the hand of Vishnu, was the origin or fountain of the river Ganges, or Ganges; which falling from the hand of the miraculous dwarf, descended thence upon his, now Vishnu's, foot; whence, expanding like its front, it fulfilled a mighty river, and was received on the head of Siva. In pictures and carvings of the latter deity, the goddess Ganga is frequently seen half concealed in the folds of his hair, and Siva is hence named Gangadhara, or Gangasheher: a name assumed also by a class of itinerants who fell that holy water through the streets of all Indian cities; it being among Hindoos equal, in expelling potentiality, to the holy water of papacy. This mythological source of the bleeding and bluffed river is a favourite subject with Hindoo poets.

In the Hindoo Pantheon, whence this article is partly taken, are many legends connected with it.

In pictures of this avatara, the dwarf is usually represented receiving the water from the hand of Beli, through a spouted vessel; sometimes accompanied by the evil counsellor Indra, or Sakra, who is represented either with only one eye, or holding his hand before the other. As the regent of the planet Jupiter, named Vrihaspati, is the counsellor or preceptor to the gods and Suras; so Sakra is the adviser of the demons or Asuras; and is constantly watchful in counteracting the divine beings, and their endeavours for the good of man; and the pious endeavours likewise of holy men. To prevent the conserving power in this avatara from accomplishing the projected end, in the punish-
ment of impiety and arrogance, perfonified in Beli, Sakra apprized him of the deceit under which he was proming the universe away. But as the monarch had too much pride to recant his royal word, the evil counsellor assumed the form of a muquito; and infinuating himself into the spout of the vessel through which the rathing stream was to pafs, arrested its palfage; when the dwarf, taking a straw to clear it, thrust out the eye of the gnat, a defect ever after retained by Sakra in all shapes. It is faid to indicate the half enlightenment of evil counfellors: till, why the one-eyed admirer of ill should be the thousand-eyed god, has not been explained. Nor will it, perhaps, be deemed worth while to enter into any lengthened explanation of the apparently ritious fables mentioned in this article; though we believe they might be explained from a confideration that all Hindoo history, religion, arts, and science, are buried in a mass of mythological legends. We will juft mention, that the fabulous fource of the Ganges, whether from the head of Siva, or from the foot of Viñhna, the latter being the principle of humidity, the former of heat, is merely a physical difpute between what in Europe would be called Neptunists and Vulcanists, but what in India assumes the form of theological controversy. Whether the Ganges be of volcanic origin, or descends from the eternal snows of Nepal, is perhaps the point here disputed between the Saiyas and Vailinivas. (See of this under the articles Saiya and Siva.) As to the muquito, Indra is the god of flowers, regent of the firmament; clofly allied to Viñhna, air being a form of humidity; and the muquito partakes, like Viñhna, of both its forms: it is born, or reproves, like the god, in water, and lives in air. But we shall pursue thefe mythological allegories no farther.

One of the eighteen sacred poemens, called Purana, is named after this avatar, (see Purana,) and details a great mass of poetical incident connected with it. The reader may perhaps smile in hearing that England is the supposed theatre of several of the incarnations of Viñhna, and of this of Vamana among them. On this point, we refer to the second article of the 11th volume of the Asiatic Researches.

VAMBA, in Geography, a river of Angola, which runs into the Coanza, near Cabembo.

VAMIGELA, in Ancient Geography, a town of Africa, in Mauritiana Cafarifia. Ptol.

VAM-KAOSE, in Geography, a small island in the Chi-nefe archipelago, where the celebrated St. F. Xavier was buried; 62 miles S.W. of Macao.

VAMPYRE, in Mythology, a name given to an imaginary demon, which, it is pretended, sucks the blood of perfons during the night, and thereby destroys them. These vampires were suppos’d to animate the bodies of dead perfons, which when dug up were found freth, florid, and full of blood. Those who were killed by vampires were said to become vampires themselves: the way to destroy them was to drive a flake through them, at which time they would give a horrid growl; and to burn the body to ashes. This species of superition occasioned, five years ago, great disturbances in Hungary and other places.

VAMPYRE, in Zoology, the Vesperitli vombrus of Linneas, called also tarnate, and by Buffon la rougette and la rouguette, is a species of bat with large canine teeth, four cutting-teeth above, and the same below; sharp black nose; large naked ears; tongue pointed, and terminated by sharp aculeated papillae; exterior toe detached from the membrane; the claw strong and hooked; five toes on the hind-feet; talons very crooked, strong, and compressed sideways; no tail; the membrane divided behind quite to the rump; varying in colour, some being entirely of a reddish-brown, and others dusky; and also in size, some having the extent from tip to tip of the wings four feet, others five feet four inches; and others extending farther than a man can reach with his extended arms. This animal inhabits Guinea, Madagacar, and all the islands from thence to the remotest in the Indian ocean. They are also found in New Holland, the Friendly Islands, the New Hebrides, and New Caledonia. They fly in flocks, obscuring the air with their numbers; beginning their flight from one neighbouring island to another, immediately on fun-fet, and returning in clouds from the time it is light till fun-rife, and during the day lodging in hollow trees; they live on fruit, and are so fond of the juice of the palm-tree, that they will intoxicate themselves with it till they drop on the ground. In New Caledonia, the natives use their hair in ropes, and in the taffels of their clubs. The Indians eat them, and declare their flesh to be very good. The French who live in the Ile de Bourbon, boil them in their bouillon, to give it a relish. While they are eating, they make a great noise; their smell is rank; and their bite,-refillance, and fiercenes, very great when taken. The ancients had some knowledge of these animals, and M. de Buffon apprehends, that from the account of them the poets formed their fictions of harpies. Linneas calls this species vampyre, conjecturing it to be the kind which draws blood from people in their sleep. The bat is so dexterous a bleeder, as to inculcate its aculeated tongue into the vein without being perceived, and then suck the blood till it is fattened; all the while fanning with its wings, or agitating the air so as to call the sufferer into a still fonder fleap. In certain parts of America they have destroyed all the great cattle introduced there by the multimians. Pennant’s Hift. Quadrupeds, vol. ii. p. 548, &c.

VAMPYRE is also a name given by M. de Buffon to the vesperiltia foedrum of Linneas, or bat with a long nose, large teeth, long, broad, and upright ears; with a long, conic, creft membrane at the end of the nose, bending at the end, and flexible; hair on the body cinereous, and pretty long; wings full of ramified fibres; a membrane extending from one hind leg to the other; no tail; but three tendons extending from the rump, and terminating at the edge of the membrane. This animal inhabits South America, lives in the palm-trees, and grows very fat. Buffon supposes it to be the species that sucks human blood. Pennant. See Andira.

VAN, VANT, or Vaunt, (of the French avant, or avaut, before,) is a term used in composition with several words in our language. As,

VAN-Couriers, are light armed soldiers, sent before armies to beat the road, upon the approach of an enemy.

VAN-Dofts, a ditch dug without the countercarp, and running all along the glacis; usually full of water.

VAN, Vanti, or Vaunt-Corps. See Corps.

VAN, or Van-Guard. See Guard.

VAN-Lay. See Vaunt.

VAN, in Agriculture, a name sometimes used to signify an implement or contrivance for winnowing, or cleaning corn with. See Winnowing Machine.

VAN, in Sea Language, denotes the foremost division of any naval armament, or that part which usually leads the way to battle, or advances first in the order of sailing. See Engagement and Fleet.

VAN, in Mining. To make a van, is to take a handful of the ore or tin-fluff, and bruise, wash, and cleanse it on a thovel; then, by a peculiar motion of the thovel, to shake and throw forth upon the point of it almost all the ore that is freed from wafer. This operation being repeated, the ore
is collected and revered, and from thence they form an
estimate how many tons of copper-ore, or how many hundred
weight of block-tin, may be produced out of one hundred
facks of that rock, of which the van is made. Pryce's

VAN-ARTENILS, in Geography, a city of Armenia, situated
two miles from a lake of the same name. It is surounded with
a good wall and deep ditch, and has four gates. On the N.
and S. are a castle, built on a high and perpendicular hill, which rifes
abruptly from the plain. This fortres can only be ap-
proached by one paffage, so narrow as to admit only two
persons abreast; it is always supplied with corn and military
stores, and in the centre of the work stands the palace of the
ag of the janizaries. This city is abundantly furnished with
water and provisions; the houfes are built of flone and tile;
the streets are spacious and well paved, and the population is
limited to about 50,000 fouls, of which number two-third-
are Turks, and the reft Curds and Armenians. The air is
pure, and the environs of the city delightful. It is four
days' journey from Bayazid, a city of one of the Turkish
princes of Armenia, twelve from Erzeroom, another of
them, five from Betlis, and about the fame distance from
Khoi.

The lake (Arifja of Ptolemy) is about 168 miles in cir-
cumference; and although the water is more sweet than that of
Urumca, it is so brackifh as to be unfit for the common
purpofes of life, according to the common opinion, though
some fay it is very good. There are four iflands in the lake,
on of which is an Armenian monastery, and 300 priets.
The traffic of the furrounding country is carried on by about
20 or 30 small boats. N. lat. 48°. E. long. 43° 55'.
On the N.W. fide of the lake, three days' journey from Van, is
Arguf (the ancient Arzes), containing 6000 inhabitants.
And in a weftern direfion from Arguf is Mohf, the ancient
Mezoene, occupying a small eminence, wahfed by the
Euphrates, over which is a bridge of 15 arches, badly built,
and thinly inhabited, but situated in a country equally fertile and
propitious. The natives of this district, amounting to
about 80,000 fouls, of which 12,000 are Yezedis, are a
bafe and degenerate race. Tobacco and manna are exported
from hence in considerable quantities. Mr. Kinners Mem.
of Perfia.

VAN, a town of Norway, in the province of Aggerhusen;
20 miles N. of Christiania.—Alfo, a river of South Wales,
which runs into the Britifh Channel, about 5 miles below
Cowbridge, in Glamorganshire.

VANAHON, a river of America, which runs into lake
Michigan, N. lat. 42° 53'. W. long. 87° 10'.

VANAMALI, in Mythology, a name of the Hindoo
god Krishna; which fce. This name is faid to be derived
from a pendent garland of flowers, with which this
frolicsome deity is usually decorated. In the following pas-
fafe he contralls his appearance, thus decorated, with that of
Mahefa, or Siva. "I am not the terrible Mahefa: a gar-
land of water lilies, with subtle threads, decks my fould-
ners; not fpernts with twifled folds: the blue petals of the
lotos glitter on my neck; not the azure gleam of poifon:
powdered fandal-wood is fprinkled on my limbs; not pale
afhes." This is addreffed to his enchanting miftrefs Rodba,
under which article a farther extract from the fame "Song"
of the world will be found. The gleam of poifon on his neck alludes
to his having drank the poifon produced by the burning
of the embers, as defcribed in our articles KURMAWATARA
and SITAKAKUNTHA; and being powdered with afhes, is
noticed in the latter part of the article SCETS of Hindos.

VANANCOPAN, in Geography, a town of Hindoo-
flan in the Carnatic; 15 miles S.W. of Trivady.

VAN-BALEN, in Biography. See BALEN.

VANBRUGH, Sir John, a dramatic writer and an
architect, was a defcendant of an ancient family in Chelfhire,
and was firft known to the public as an officer in the army,
being confidered as a man of wit and a pleanfent companion.
The firft play which he firfhed was "The Refpafle", and it was aced with great succefs in 1697. This was
followed, in the fucceeding year, by "The Provoked
Wife", and in the fame year appeared his "Alop,"
blending humour with fadine and ufeful morality. In
1702 appeared his "False Friend!" and he was now
knigh ted, and advanced to the poff of Clarencieux king-
ats. When a theatre was erected in the Haymarket,
it was placed under the management of Vanbrugh and
Congreve by Betterton and the other patentees; and it
was opened in October, 1705, with a comedy by Vanbrugh,
titled "The Confederacy," which, though the ballet
written, is the moft licentious of this author's dramatic pro-
fuctions, belides three more pieces, imitated from the
French; but finding the concern irksome, he difpoled of his
shares. The pantomime of "The Journey to London" was begun by him, but finifhed by Cibber. In
speaking of Vanbrugh, Pope has blended prais with cen-
sure, when he fays,

"How Van wants grace, who never wanted wit."

His taste and talents as an architect were firft exhibited in
the theatre in the Haymarket, for which he obtained sub-
fcriptions; and to him was committed the erection of the
palace of Blenheim, voted by the nation to the duke of
Marlborough. In 1716, king George II. appointed him
surveyor of the buildings at Greenwich-hofpital, comp-
roller-general of the royal works, and surveyor of the gar-
dens and waters. On a visit to France, he employed himself
in taking views of the fortifications in that kingdom, which
caufed him to be apprehended and committed to the Bafile;
but when he was obferved to amufe himfelf in prifon by
making fketches of comedies, he was liberated, as a harm-
less perfon, without any application from home in his favour.
As an architect, he was engaged to build several great
houfes in England, besides Blenheim; but in this capacity
he has unfortunately been tranmitted to potterfry rather as an
object of ridicule than of admiration. Mr. Walpole has
passed upon him a fevere cenfure, when he fays that "he
wanted all ideas of proportion, convenience, and propriety.
He undertook vast designs, and compofed heaps of little-
nefs. The style of no age, no country, appears in his
works; he broke through all rule, and compefaated for it
by no imagination. He seems to have hollowed quaries
rather than to have built houfes; and should his edifces, as
they seem formed to do, outlaid all record, what architec-
ture will potterfry think was that of their ancestors?" The
following epigrammatic epitaph was written for Vanbrugh
by Dr. Evans, and accords with the above character of his
works:

"Lie heavy on him earth, for he
Laid many a heavy load on thee."
one "who was a man of wit and of honour." He died of a queney, at his house in Whitehall, in the year 1726.

VAN CAMPENS, in Geography, a town of the state of New Jersey; 32 miles N.W. of Morristown.

VAN-CHOU, an island in the East Indian sea. N. lat. 18° 50'. E. long. 110° 40'.

VANCOUVER's Fort, a fort of Kentucky, at the union of the two branches of Sandy river.

VANDALANDA, in Ancient Geography, a country of Asia, in Sogdiana, between mounts Caucasus and Imaus.

Ptolomy.

VANDAL, ANTONY, in Biography, was born in Holland in 1638, and though he manifested an inclination for study in his youth, his parents placed him in the department of commerce. At the age of 30, however, he refuted his literary pursuits, and graduated as a physician; and he was also for some time a preacher among the Mennonites. His attachment to study prevailed at length over every other occupation, and his literary character was established by many valuable works. Of these the most noted was "Differtationes de Oraculis Ethniciorum," first printed in 1683, 12 mo., and afterwards in 1700, 4to. His opinion was, that the heathen oracles were mere impostures, and that they did not cease at the coming of Christ; which at the time was a bold assertion, as it contradicted the sentiments of some of the fathers. Fontenelle abridged these dissertations in his "Histoire des Oracles." (See the article Oracle.) In 1696 he published a work, "On the Origin and Progress of Idolatry," which contained "A Dissertation on true and false Prophecy;" "A Dissertation on the Narrative of Arifenas on the Seventy Interpreters;" "The History of Baptisms, Jewish and Christian;" "A Dissertation on Sanchoniatho;" and "Dissertations on ancient Marbles." Some of these have been published separately. In all his writings, Vandal manifested solid erudition, united with facility and a spirit of free inquiry; but he was a methodist, and his style is obscure. He was allowed, even by those who differed from him in opinion, to be a man of great probity, of an agreeable disposition, and entertaining conversation. His lot was that, which has not been uncommon with persons of literature, namely, indigence; for he sold his books before his death, which happened at Haarlem in 1708. Morel. Le Clerc.

VANDALS, in Ancient Geography, a people of no very high antiquity, who were originally a Gothic nation. (See Goths.) Pliny and Procopius concur in this account of their origin; and the latter writer, more especially, affirms in express terms, that the Goths and Vandals, though distinguished by name, were the same people, agreeing in their manners, and speaking the same language. They were called Vandals, from the Gothic word "Vandeln," which signifies to "wander," because they often changed their situation, migrating from one country to another. They are supposed to have come originally out of Scandinavia, with the other Goths, under the command of king Erich, and to have settled in the countries now known by the names of Mecklenburg and Brandenburg. When Berig, king of the Goths, several ages afterwards, brought with him a colony of Goths from Scandinavia, and settled in Pomerania, he subdued the Vandals, who inhabited those countries, and incorporated them with the new settlers. In the reign of Augulfus, one of the Vandals, beingbrightained in their own country for want of room, took up their abode on the banks of the Rhine; but were driven from thence by Tiberius and Dufus, and compelled to return home. Their country being overflowed with inhabitants, they soon afterwards pursued an eastern route, and driving out the Scavi, who occupied the territory that lay between the Bosphorus Cimmerius and the Tanais, and taking possession of their country, assumed the appellation of the ancient inhabitants. Some of them, several ages after, in the reign of Mauritius, which began in 586, settled in Dalmatia and Illyricum, to which they gave the name of Schalonia; and others migrated to the eastern parts of Dacia beyond the Danube, a province which comprehended the countries now denominated Transylvania, Moldavia, Wallachia, and the eastern parts of Upper Hungary. From those who remained in Germany, their ancient Poles and Bohemians, they supposed to have derived their origin; but the Vandals, who, under Godgerulf, their king, entered Gaul, and afterwards settled in Spain and Africa, came, as Procopius says, from Dacia and the vicinity of the Palus Moritis. As the Vandals were a Gothic nation, they retained the customs, manners, religion, and form of government, that subsisted among the Goths. The first of their kings mentioned in history is Godgerulfus, under whose command they entered Gaul in 406. He was succeeded by Gunerich, who passed, in 409, from Gaul into Spain, and settled in Galicia. His successor, Generich, abandoned Spain in 428, and passed with his valets into Africa, which the Vandals possessed till the year 533; when, under Gelimer, an end was put to their dominion by Belisarius, and Africa was reunited to the empire. Although the Vandals are said to have been inferior in power and courage to all the other barbarous nations, they nevertheles made themselves masters of the most fertile provinces of the empire. They became protelytes to Christiandom at the same time with the Goths, embracing the sentiments of Arius, in common with the other Goths, and becoming irreconcilable enemies to the Catholic church. Salvianus extols their continence and chasity.

It was about the year 1667 that they began to be troublesome to the Romans, in the reign of M. Aurelius and Lucius Verus; when forming an alliance with other barbarous nations, they invaded the empire, plundered several cities, and, having put to flight the Roman armies, committed every where unparalleled ravages. Having taken possession of Pannonia, they retained it till they were expelled in the year 170, by M. Aurelius. They afterwards entered into an alliance with the Romans; and in 180, it was one of the articles of peace concluded between the emperor Commodus and the Aleman, that they should not make war upon the Vandals. In the second year of Aurelian's reign, A.D. 271, the Vandals passed the Danube, laying waste the neighbouring provinces; but Aurelian compelled them to retire with great precipitation, and having overtaken them in their retreat, obliged them to sue for peace; which was granted, on condition of their delivering, as hostages, the sons of their two kings, and other persons of distinction. Two thousand of their best men were incorporated among Aurelian's own troops. After his death, they entered Gaul; but they were defeated by Probus in several battles, and obliged to withdraw themselves at the approach of the Roman army. Refitting the infinits of the Roman soldiery, they made an attempt to recross the Rhine, but sustained a great defeat; and proving unfaithful to their engagements, after having obtained peace, Probus marched against them, put many to the sword, took a great number of prisoners, among whom was their king, and afterwards sent them into Britain, where they were fupposed to have settled in the neighbourhood of Cambridge, giving name, as it has been said, to the village of Vandalburg. Probus allowed several of them to settle in Thrace, which was almost depopulated.
The next mention of the Vandals that occurs is in the eighth year of the reign of Diocletian, when they engaged in a war with the Goths. About the year 406, or the twelfth of Honorius's reign, they made an irruption into Gaul; but in attempting to cross the Rhine, they were slaughtered by the Franks; and being relieved by the Alans and Suevians, they obliged the Franks to retire, and actually entered Gaul. Having passed through Germania Prima and Gallia Belgica, they took possession of Aquitain, the most fertile and opulent province of Gaul; and advancing as far as the Pyrenean mountains, they ravaged all the neighbouring provinces. Conflantine, however, having been proclaimed emperor by the British legions, passed from Britain into Gaul with a powerful army, and defeated the Vandals and other barbarians in several battles, and at length granted them peace, without ripulating as a condition their leaving the country. The Vandals soon afterwards took up arms, and besieged several cities of Gaul, under Maximus, who assumed the honour of being emperor, in opposition to Conflans, the son of Conflantine. Finding themselves more vigorously opposed than they expected, they marched towards Spain, which was then in a distracted state, and in the year 409 entered the country; and before the end of the year, Conflans, obliging Conflantine to abandon it. After having reduced the province of Spain to a deplorable condition, they conjoined with the Alans and Suevians in dividing the country between them, and devoted themselves to the operations of agriculture. In this partition, Galicia fell to the share of the Vandals and Suevians, and Britain to those Vandals that were called Silingtians, who were supposed to have given to their portion the name of Vandalusia, afterwards changed into Andalufsia. In the year 416, Vallia, king of the Goths in Gaul, having made peace with the Romans, undertook to drive the barbarians out of Spain; and in 422, Honorius, having heard of the reduced condition of the Vandals in Spain, in consequence of the conduct of Vallia, determined to recover the provinces which they possessed. But his attempts for this purpose were rendered ineffectual by a signal defeat. In consequence of this victory, the Vandals became powerful, established themselves in Andalufsia, almost destroyed the city of Cartaghesia, and extended their ravages to the Balearic islands. In the year 428 or 429, Generic, the king of the Vandals, assembled them together, with their wives, children, and effects, and abandoning Spain, crossed the straits of Gibraltar, and landed in Africa. After their arrival, they gained several victories over the Romans, and overran the country, that Cirta and Cartaghes were the only two strong places in Africa possessed by the Romans. At length, viz. A.D. 435, a peace was concluded between Valentinian and Generic; but though the moderation of the Vandal sovereign was highly extolled, he neitherfeels feized Carthage, A.D. 439, whilst the Romans were engaged in a war with the Goths in Gaul; and thus the Vandals remained masters of the proconfulon province of Byzacene, Getulia, and part of Numidia. The capture of Carthage created an alarm in Italy; and preparations were vigorously made for putting Rome in a state of defence, and for inducing all ranks of people to take up arms for the preservation of the country. In the year 435, Generic took and plundered Rome; and carried over with him into Africa the empress Eudokia, and her son, the Emperor Honorius, leaving them till the year 462, marrying Eudokia to Hunneric, his eldest son, who had by her Hilderic, afterwards king of the Vandals in Africa. Upon his return to Africa, Generic subdued the countries that were still in the hands of the Romans. The emperor Majorianus, being disappointed in his views and plans for the conquest of Africa, concluded a peace with Generic, who, after the death of the emperor in 461, sent a powerful fleet to pillow the coasts of Sicily and Italy, and even made himself master of Sardinia. He afterwards took occasion to ravage Peloponnese and the Greek islands, whence were carried off many captives. Leo reenforced the afront offered by Generic to the eastern empire, and prepared for revenge by carrying the war into Africa. In the progress of his powerful armament, Sar- dina and Tripoli were recovered from the Vandals; but whilst Generic solicited of the Roman admiral a truce of five days for settling the terms of his submission to Leo, he contrived to destroy the whole Roman fleet that was armed against him. In the year 475, he concluded a peace with Zeno, the successor of Leo, who, renouncing all claim to the provinces of Africa, yielded them for ever to Generic and his descendants. Soon after this event, Generic died, A.D. 477; but the peace was religiously observed by his successor, till the reign of Justinian, who, espousing the cause of Hilderic against his brother Glimmer, who had usurped the crown, drove the Vandals out of Africa, and reunited those provinces to the empire. (See Belisarius.) Africa had been their empire, it now became their prison; nor could they entertain a hope, or even a wish, of returning to the banks of the Elbe, where their brethren, of a spirit less adventurous, still wandered in their native forests. In the country between the Elbe and the Oder, several populous villages of Lusatia are inhabited by the Vandals: they still preserve their language, their customs, and the purity of their blood; support, with some impatience, the Saxax or Prussian yoke; and fuse with secret and voluntary allegiance the descendant of their ancient kings, who, in his garb and present fortune is confounded with the meanness of his vassals. The name and situation of this unhappy people might indicate their descent from one common stock with the conquerors of Africa; but the use of a Slavonian dialect more clearly represents them as the last remnant of the new colonies, who succeeded to the genuine Vandals, already scattered or destroyed in the age of Pro- copius. Anc. Un. Hist. vol. xvii. Gibbon's Hist. Rom. Emp. vol. i. vii.

VANDELEYVILLE, in Geography, a town of France, in the department of the Meurte; 9 miles N.W. of Mirecourt.

VANDELLIA, in Botany, was so called by Linnaeus, at the suggestion of Browne, after his correspondent Dr. Dominick Vandelli, who published at Padua, in 1764, a quarto volume in Latin, on the hot-baths of that neighbourhood, with notices of some cryptogamical plants inhabiting therein. Being afterwards appointed superni- tendant of the royal botanic garden at Lisbon, he published there, in 1771, a small Flustrum Plantarum, dedicated to Sir Joseph Banks, describing some tuppofed new genera, and several new species, with a few figures. Dr. Vandelli is also the author of one or two zoological tracts; and he wrote against Haller's doctrine of the insufficiency of the tendons and membranes, to the great displeasure of that illustrious physiologist. This veteran in botanic science visited London, in 1815, at a very advanced age, and, if we mistake not, is since dead.—Linn. Mant. 12. Schreb. Gen. 419. Willd. Sp. Pl. v. 3. 343. Mart. Mill. Dict. v. 4. Julii. 122. Lamarck Hirtt. t. 352. (Matonius; 641. Jul. 119.—Clas and order. Phy- domania Angiospermae. Nat. Ord. Perennes. Linn. Scopu- larie. Julii.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, in four deep, awl-shaped, equal segments, the uppermost sometimes divided, permanent. Car. of one petal, ringless; tube as long as the calyx; limb small; 3 stamens on the culture;
entire; lower dilated, two-lobed. *Stam. Filaments four; two from the disk of the lower lip, curved upwards; two from the throat, higher up; anthers ovate, connected in pairs. Pet. German oblong; style thread-shaped, the length of the filaments; stigmas two, ovate, membranous, reflexed. *Peric. Capule oblong, of one cell. Seeds numerous.

2. *V. pratensis. Oblong-leaved Vandelilia. "Vahl Eclog. v. 2. 48." Wildl. n. 2. (Matourca pratensis; Aubl. Guian. 632. t. 259. Luteicava, five Scoparia; Pit. Braf. 246.)—Leaves ftalked, elliptic-oblong, acute, finely downy on both fides.—Native of moift ground in Cayenne; about the borders of meadows near the town, flowering almost all the year. It is known by the name of Wild Bafli (*Bafli ficawage), and esteemed a good vfforlery. The flems are feveral, erect, two feet high, leafy, fquare, forked. Young branches, as well as the leaves, soft to the touch, clothed with fine fturbulence. Flowers blueith, axillary, motifly foliary. They are delineated in Aublet's figure as having the upper lip in two lobes, the lower in three, which does not agree with the Linnaean generic description, copied above from the *Montifia. Yet the other characters, and the habits of the plants, anfwer fo well, that we are perfuaded they mutt, as Schreber fupffected, belong to one genus. This opinion is confirmed by Vahl, who mentions this fecond species as of very frequent occurrence, by the road-fides in South America, from Trinidad to Brazil. The root is annual. The fame learned botanift had, no more than ourselves, any opportunity of examining the rare *Vandelitia diffusa alive, nor does it appear whence Linnaeus took his defcription; except possibly from two or three very in-complete dried ftimens, which are now scarcely fufficient to affift in forming an opinion on the fubjeft.

VANDERWERF, ADRIAN. This ingenious painter was born at Ambacht, near Rotterdam, in 1659, and received the principal part of his education under Eglon Vander Neer. At the age of 18, he left that matter, and becoming acquainted with M. Fluiik, who polifhed an ex- tensive collection of drawings by Italian masters, to which he had constant access, he, by this aid, and also by drawing after fads from antique figures, formed a fyle of defign much more elevated and pure than that of his countryman and contemporaries.

At about the age of 37, his works attracted the notice of the elector palatine, on his visit into Holland; and he commissioned him to paint for him a picture of the Judgment of Solomon, and also his own portrait, to be preffented to the Florentine gallery of artifics; and he invited him to bring the pictures to Duffeldorff. The following year he effected that object, and the elector was defirous of retaining him in his service; but to this Vanderwerf would not con- sent, but engaged to devote to him fix months of the year, for which he received a liberal pension. In confequence, the gallery of Duffeldorff is the theatre of Vanderwerf's glory, and his pictures are numerous; but they are not very uncommon in this country. The charater of them is given by fir Joshua Reynolds, who, in his critical tour into the Netherlands, says, "they (the pictures by Vanderwerf at Duffeldorff) are twenty-four in number in one room, three of them as large as life; a Magdalen, whole length, and two portraits. His pictures, whether great or small, certainly afford but little pleafure; one of the principal caufes appears to me, to be his having entertained an opinion that the light of his picture ought to be thrown fequently on the figures, and little or none on the ground or sky. This gives great coldnefs to the effect, and is fo contrary to nature, and the practice of thofe by whom works he was furrounded, that we cannot help wondering how he fell into the fllow. His naked figures appear to be of a fubfance much harder than flefh, though his outline is far from cutting, or the light not united with the fhafe, which are the molt common caufes of hardnefs; but it appears to me, that, in the prefent infance, the hardnes of manner proceeds from the foftenfs and union being too general; the light being every where equally loft in the ground, or its fllow, and thus producing the appearance of ivory or plaftier, or fome other hard fubfance." There is also a want of tranparence in his colouring, and he has con- stantly the deficf of Rembrandt, that of making his light only a fingle fpot. However, to do him justice, his figures and his heads are generally well drawn, and his drapery is excellent. He died in 1727, aged 68.

He had a brother, Peter Vanderwerf, who copied his pictures, and imitated his manner. Though he occasionally painted history, yet his pictures more frequently represent domeftic fcenes; which, though not equal to his brother's, are very highly wrought, and have fometimes been miftaken for his. Peter died in 1718, aged 53.

VANDEVELDE, ADRIAN. This excellent painter was born at Amsterdam in 1659. He difcovered, whilst he was yet at school, a decided difpofition for paintings, and covered the walls of his father's houfe with fcetches of all kinds of animals, drawn with an intelligence very unequal at that early period of life, and which induced his father to place him under the tuition of J. Wynants, where he made a very extraordinary degree of progres. Wynants taught him the practice of drawing from nature, and studying in the open air. It was his constant cuftom to pafs his days in the fields, defigning every thing effential to his perfuits; and in this mode, infinitely more variety may be obtained than the moft inventive genius can supply without it. Besides this useful mode of study, he alfo applied himfelf to draw from the human figure, and obtained a confiderable degree of excellence. In this refpeét he very far fuperfaced his matter, who afterwards conftantly employed him, as he had previously done Wouvermans and Lingleback, to decorate his landscapes with figures and animals; as alfo did Hackaert, Hobbima, Vander-Heyden, and others, thus giving an additional interef to their admirable performances.

The fcenes which Adrian Vandevelde chofe for the exercise of his art are in general very confined, and feldom above the ordinary appearance of common nature; but they are
are rendered with so much purity of colour, and fullness and perfection of execution, that they captivate, notwithstanding their simplicity. His animals, which are generally the subjects of his pictures, are designed with correctness, and have a life and air of motion which is to be found in those of any other marine painter. His vessels are correctly drawn, and the sails, the rigging, finished with a delicacy perfectly astonishing, and with unexampled freedom. No one ever surpassed the purity and truth of his tints: whether he represent the serenity of the calm, or the majestic obscurity of the storm, an undeviating correctness and fulness adorn his canvas, and render his works precious in the eyes of all beholders. He died in 1707, at the age of 74.

**VANDYCK, Sir Anthony, in Biography.** This most justly admired painter was born at Antwerp in 1599, and, according to Houbraken, was the son of a painter on glass, who first instructed him in the elements of the art of painting, but afterwards intrusted him for further tuition to the care of Henry Van-Balen, a painter of considerable reputation. He had made a rapid progress under that master, when the increasing fame of Rubens, and the beauty of his works, inspired him with a desire of becoming a disciple of so able an instructor; and his wishes were soon crowned with succés. Rubens soon beheld with pleasure the value of the talents brought by Vandyck into his school, and found in him an able and useful assistant in forwarding his larger works from the sketches he himself had prepared; and it was not long ere an incident established Vandyck's superiority above his fellow pupils, and rendered him at once an object of interest and of envy. Whilst Rubens was employed upon his renowned picture of the Defeat from the Crofs, his pupils were anxious to see it in its progress, and procured admission to his study during their master's absence. One of them, in the wantonness of youth, pushed Diepenbeck, and he fell against the picture, and effaced an essential part of it, on the face of the Virgin, and the arm of the Mary Magdalen, which Rubens had just been painting. Confutation and alarm filled every one present; and to prevent, if possible, the discovery of the accident, John Van-Hoec proposed that Vandyck should endeavour to reform the picture to the state in which they found it. He did so; and the next morning, when Rubens came into his room, on regarding the picture, he is said to have remarked, "there is a hand and an arm which are by no means the word of what I did yesterday;" and though afterwards

4 F
VANDYCK.

afterwards he might have disovered the mischief, he did not change the painting.

It has been affected by D’Argenville and others, that this circumstance, and the growing ability of Vandyck, alarmed the jealousy of Rubens, and that, in consequence of it, he advised his pupil to renounce historical painting, and adhere to portraiture. But this calumny must be regarded as refuted, by the mere consideration of Rubens having advised Vandyck to go to Italy, where he himself had reaped so much benefit, and where history would be the more sure to rivet the attention of a student. Had he, however, advised him to adhere to portrait painting, it is but a farther proof of his clear perception of the native turn of mind of Van
dyck, and a liberal hint how to employ his talents to most advantage, not originating in the mean passion to which it has been ascribed, but in judgment and good-will. That they did not separate upon unfriendly terms is evident, by Vandyck acting upon his advice, as to going to Italy; and presenting his master, previous to his departure, with two historical pictures, and a portrait of his second wife Helen Forman; and receiving from Rubens in return a present of one of his finest horses.

In 1619, when he was 20 years old, Vandyck left his native city for a residence in Italy, and first visited that emporium of colour, Venice, where he copied and studied with great attention, and imbibed the real spirit, of the works of Titian. At Petworh, the seat of the earl of Egremont, are two portraits of Sir James and lady Shirley (who was a Perian lady,) in Persian costume, which ex
hibit, in the freedom and fulness of colour with which they are painted, the perfect understanding he had of the style of that great Venetian master. From Venice he went to Genoa, where his power was recognised, and his pencil em
ployed, by the principal nobility in their portraits, as well as by several churches and convents, for which he painted historical pictures; and nothing is more astonishing in the history of the art, than the rapidity and facility with which so great a number of works was produced by this extra
ordinary artist. He is reported to have hung up in his studio, on his return from Italy, forty copies made by himself from pictures by Titian, though he was much engaged in original works during his residence there. After some stay at Genoa, he went to Rome, and was there introduced to that patron of elegant literature, the cardinal Bentivoglio, who had been nuncio from the pope in Flanders, and to whom, of course, his talents must have been already known. From this celebrated character he painted that prince of portraits, which for several years was an ornament of the gallery of the Louvre, but now is returned to its original situation, the museum at Florence. Nothing in painting has ever surpassed the life and vigour of the head in this surprizing and agreeable picture. He painted some historical subjects for the cardinal, and also several portraits of distingushed persons; but not uniting with his countrymen, then at Rome, in the Bentvogel society, they rendered his residence there unpleasant to him, and he returned to Genoa, where he was cared for and honoured, and met with constant employment. Whilst there, he was invited to Palermo, to paint the portrait of Philibert, prince of Savoy, the viceroy of Sicily, and was engaged in several commissions for the court; but the plague breaking out, obliged him to leave that place, and he soon after returned to Flanders.

The reputation of his growing talents had led his country
men to an anxious desire of witnessing his power, and several religious communities advanced to employ his pencil. His first public work was his celebrated picture painted for the church of the Augustines at Antwerp. For a time it adored the walls of the Louvre, but is now restored to the church whence it was taken. The subject is St. Augustine in Ecstasy, supported by angels, with other fants; of which there is a print by De Jode. Of this performance, which procured him great reputation, Rubens was one of the most zealous admirers; but Sir Joshua Reynolds observes, "that in some measure it disappointed his expectation: that it has no effect from the want of a large mass of light." In order to judge better of historical subjects, it must be observed, that as it was originally painted by Vandyck, St. Augustine was drest in white, and with the two angels that support him, formed a principal mass of light; but that the monks insiled upon their patron being drest in black, and would not pay for the picture till it was so done.

Commisions now came fast upon him, and most of the principal public edifices of Antwerp, Brussells, Ghent, and Mechlin, were embellished with the productions of his pencil. About this time he painted that beautiful series of small portraits of the eminent artists of his time, which, for character, for variety, and exquisite execution, remain unequalled. Several of them he etched himself, and the rest have been engraved by the best engravers of that day. One of his most excellent historical productions was painted for the church of the Recollets at Mechlin, which also paid a visit to the Louvre, but was returned with the rest of the spoil from Flanders. Its subjeet is the Crucifixion, and Sir Joshua says of it, that, "upon the whole, it may be considered as the finest of Vandyck’s works, and establishes his fame to the title of an historical painter."

The taste and ability thus displayed by this great artist did not influe him from till treatment by his contemporaries, by whom he was accused of tameness and inutility; and in addition to this, he endured a great mortification from the canons of the collegiate church at Courtray, for whom he painted the Elevation of the Cross, befoeing upon it all the power of his art. The picture being completed, it was sent to the place of its denomination, when, instead of receiving the due meed of praise for its extraordinary merit, it was pronounced by the chapter to be a detestable performance, and they treated the author of it as a miserable artist; and with difficulty he could procure payment for his picture. It was not till the picture had been seen and commended by several artists and connoisseurs, that they became sensible of their error; and then, to atone for such foolish and inoffensive conduct, they resolved to commiss him to paint two more pictures for their church; but Vandyck, with becoming indignation, refused to waive his talents upon men fo unworthy of regard, and fo little capable to judge of works of art.

Soon after this, he accepted an invitation from Frederic, prince of Orange, to visit the Hague; and there he painted the portrait of that prince, and those of his family, with many of the principal personages of the court.

The patronage which it was understood to be found at the English court, where Charles I. then reigned, induced Vandyck to visit England in 1629, when he lodged with his friend Geldorp, the painter; but had not the good fortune to attract the notice of his majesty. Disappointed, he returned to Antwerp, with intent to pass the remainder of his life there, when a portrait of Sir Kenelm Digby, which he had painted, was shewn to Charles, and he immediately gave orders for an invitation being sent to the painter to return; and accordingly in 1631 he did so, and was most graciously received by the king.

On this second arrival, he was lodged at Blackfriars, at the king’s expence; and his majesty was so much delighted with his performances, that he often went by water to visit
visit him, and see him paint; frequently fitting to him for his portrait, having others of his wife and children; and on the 5th July, 1632, conferred upon him the honour of knighthood. Afterwards granted him an annuity of 200£, a-year for his life.

Popularity and occupation now flowed in full tide upon him, and the rapidity of even his pencil could scarcely keep pace with the commissions he received, for portraits especially. There are few houses of the old nobility of the country wherein there are not to be found some pictures by Van Dyck. In the king's palaces, the portraits of Charles and his queen and family are numerous. One of a very fine quality adorns the Louvre. At lord Digby's in Warwickshire, is a great number of his portraits. At Petworth, besides the two pictures mentioned above, painted at Venice, are eleven portraits by him, all of the Percy family, or their immediate friends. At Warwick Castle is the like number; and in each are works of the first-rate quality. At Wilton, the grandest of his pictures painted here adorns a magnificent apartment; it is of Willicum, earl of Pembroke, and his family. The style in which it is executed is large and grand, and of a much higher quality than his later productions exhibit, which, in comparison, have only delicacy to compete with the boldness and breadth of this. There are here also many others of his hand; but it would be an almost endless and a needless task to enumerate the pictures which he painted during the sixteen years he resided here, the greater part of which comprehended those of a large size. The prices he was paid confined them to the higher classes, and for them only he wrought. For a half length he had 40£, and for a whole length 60£. This, which at that time was a large sum, and the facility of his execution, together with his pension, enabled him to indulge a natural taste for splendour and luxury. He kept a splendid table, and often detained those who sat to him to dinner, both for society, and the opportunity of studying their countenances, and for touching their pictures after dinner. He was, however, indefatigable, as appears from the number of his works, which, though he died so young, are scarcely surpassed in number by those of Rubens. His practice was peculiar. Sir Peter Lely told Mrs. Beale, that Laniere the painter assur'd him, that he had fast seven entire days, morning and evening, to Van Dyck, for his portrait; and that he would not let him look at the picture, till he was himself satisfied with it. He was addicted to pleasure, was fond of music, and treated musicians with liberality; was a generous patron of all ingenious men, and painted the portraits of many gratuitously. But he paid dear for his indulgence; his luxurious and sedentary life brought on the gout, and hurt his fortune; and he unwisely could not, like his master, resist the temptation of the time, the pursuit of the philosopher's stone; in which perhaps, as Mr. Walpole says, he might have been encouraged by his friend sir Kenelm Digby. Towards the close of his life, the king bestowed on him the daughter of the unfortunate lord Gwyry (Maria Rutten) for a wife; with whom he acquired only honour and beauty, and by whom he left one daughter, afterwards married to Mr. Stepney, who was an officer of the horse-guards on the re-establishment of the royal family.

Soon after his marriage he revisited his native city, and from thence went to Paris, hoping to be employed in the decoration of the gallery of the Louvre; but was disappointed, in finding the commissioms given to Poussin, who had been brought from Rome expressly for this purpose. Van Dyck then returned to England, and still enmity of his great master's known, was ambitious of being employed upon some great national work; and proposed to the king, by sir K. Digby, to paint the walls of the banqueting-house (of which the ceiling had already been adorned by Rubens) with the history and procession of the order of the Garter, for which he asked 8000£; a proposal far more agreeable to the taste than to the purse of the king; and if it had been accepted, two events which soon after occurred, would have totally prevented its completion, viz. the double triumph of death over the patron and the artist. The former indeed lived some years after the decease of the latter; but his political demise followed shortly upon that event, which occurred on the 9th December 1641, when he had only attained the age of 42.

Though Van Dyck produced many valuable works, as we have seen, in historical painting, yet it by no means appears to have been his forte; as he seldom exhibited much expression, but a tame sweetness of effect reigns in them. It is doubtless in portraiture that he stands most decidedly conspicuous, and he may be placed at least alongside of Titian: for if the palm of superiority be given to the latter for his heads, the former must have equal praisr for every other part of his pictures, and particularly for the ordonnance of the whole. His better compositions are conspicuous for their unity and propriety; but his great quality is his perfect understanding of the nature of all the parts, the head, the hands, drapery, skies, &c. and the delightful union of tone and beauty of execution, which he never failed to give. In identity of character he was not often conspicuous: perhaps the cardinal Bentivoglio is the most perfect exemplar; but sir Joshua Reynolds has superadded that invaluable quality to all that he might have acquired from the works of Van Dyck or of Titian.

Van Dyck, Philip, known by the name of the little Van Dyck, was born at Amsterdam in 1618, of a different family to that of sir Anthony, and was a disciple of Boonen, under whose tuition he remained till he had become almost capable of teaching his instructor. He painted small portraits, and from them obtained his cognomen; but was more successfully employed in painting conversation pieces, ladies at their toilets, gay assemblies, &c. which he composed and painted ingeniously. He died at the Hague in 1752.

VanDyke's Islands, in Geography, two islands, Great and Little, in the West Indies, situated to the north-west of Tortola.

VANE, Sir Henry, in Biography, a person of peculiar talents and disposition, who exhibited a conspicuous character during the period of the English Commonwealth, was the eldest son of sir Henry Vane, of Hadlow in Kent, and Raby Castle in Durham, secretary and treasurer of the household to Charles I. He was born about the year 1612, educated at Westminster school, and at the age of sixteen admitted as a gentleman-commoner at Magdalen college, Oxford. Here he remained for some time without matriculation, of which he disapproved; and having visited France and Geneva, he returned with an avowed disaffection to the liturgy and government of the English church, which no efforts of bishop Laud were sufficient to overcome, although he was employed by the king for this purpose. In the year 1634 he joined a number of persons, who being made unhappy by the measures that were pursued at home, emigrated to New England; and being favourably received in that colony on account of his rank and talents, he was soon appointed governor of the province of Massachusetts. Here he invented an odium by his patronage of Antinomianism; and having taken an active part in diluting those sentiments with regard to religion that occasioned conspicuous and injurious to the colony, he was excluded from his high office,
and in consequence of this degradation, he returned privately to England in the year 1639.

VANE.

and in consequence of this degradation, he returned privately to England in the year 1639.

experience having taught him wisdom, and having produced a change in his principles and temper, he married a lady of good family, and occupied the place of joint-treasurer of the navy with Sir William Ruffell. Devoting himself to business, he was chosen representative for Hull in the parliament of April 1640, and the subsequent Long parliament. He was also so much in favour with the royal party, that he was knighted by the king. His public conduct seems at this time to have justified the character given of him by Lord Clarendon, who says, "he was a man of extraordinary parts, a pleasant wit, a great understanding, which perced into and difcerned the purposes of other men with wonderful sagacity, whilst he had himself vulturn clauflum, that no man could make a guess of what he intended. He was of a temper not to be moved, and of rare dilimination, and could comply when it was not reasonable to contradict, without losing ground by the concession."

A crisis, however, was approaching, which required his taking a decided part; and accordingly he enlisted with those who were adverse to the court. On occasion of the trial of Lord Strafford, he produced from his father's papers evidence against him, which served in no small degree to produce his condemnation. He also carried up to the lords, the articles of archbishop Laud's impeachment. In 1643, he was nominated one of the Assembly of Divines for the settling of church government; and he was appointed in the same year one of the parliamentary commissioners for negotiating a treaty with the Scotch. His perfusion induced the signature at Edinburgh of the Solemn League and Covenant; and in accomplishing this object, he overreached the Presbyterians of that country by an article which established the exiling form of religion in Scotland, but left ambiguous the nature of the reform in the two other countries. About this time he became sole treasurer of the navy, but without any view to his own emolument: for he gave up his own patent for life from the king, and for an agent whom he substituted in his own place, he obtained a salary of 2000l. per annum, the residue being brought to the public account. Of his religious principles and character, who were lord Clarendon favors in the following terms: "Vane was a man not to be described by any character of religion, in which he had swallowed some of the fancies and extravagancies of every sect or faction; and was become (which cannot be expressed by any other language than was peculiar to that time) a man above ordinances, unlimited or unrestrained by any rules or bounds preferred to other men, by reason of his perfection. He was a perfect enthusiast, and without doubt did believe himself inspired, which so far corrupted his reason and understanding, that he did at some time believe he was the perfon deputed to reign over the fants upon earth for 1000 years." In connection with the party denounced Independents he opposed terms of peace, when he acted as one of the parliament's commissioners at the treaty of Uxbridge in 1645; and when he negotiated in the Isle of Wight in 1648. Although he had from artifice or feeling no concern in the king's death, he was one of the council of state invested with supreme power after that event. He was a steady adherent to the republican government, under which he occupied an important station; and in 1649 he was one of the commissioners sent into Scotland for introducing the English government there, and for effects an union between the two countries.

On this occasion he is represented by Burnet as having fomented the division prevailing between two parties in the kirk, and as having discouraged all attempts to unite them, with a view of maintaining over them more Catholic temporal authority, whilst they disagreed among themselves. To Cromwell, in all his attempts to assure the supreme power, he was a determined adversary; and on account of his efforts for this purpose, he was summoned before the council by Cromwell in 1656, and ordered to give security that he would not disturb the nation, and for his refusal he was for a short time imprisoned at Carlisbrook castle; and though attempts were made to intimidate him by disputing his title to the Ruby estate, he remained inflexible during the period of the usurpation. In Richard's parliament of 1659, he was a representative of the borough of Whitchurch in Hampshire, and was active in his endeavours for restoring the republican government, and his spirited speech for this purpose, on record, is said to have had no small effect in subverting the new phantom of single authority. After the revival of the Long parliament, he was nominated one of the committee of safety, and proposed a new model of government, of which it was a fundamental principle, that in the delegation of the supreme power from the people to their representatives, there were some points which could not be affirmed as self-evident, and of which it was of the highest importance that the king or single person to the legislative or executive power, and the exercise of compulsion in matters of faith and worship. Baxter affirms, that Vane's model was that of a "fanatic democracy!" and his notions have been as much reproached by Presbyterian writers as by Episcopalians.

Vane maintained his adhesion to the republican cause, and prosecuted his efforts for supporting it, till the contest was terminated by the Restoration. His conduct on this occasion, though he was not one of the regicides, caused his name to be invested in the lot of those who were excluded from the act of indemnity. Apprehending no personal danger, he continued in his house at Hampstead, till he was taken into custody and committed to the Tower, as a person whom it was hazardous to permit to be at large. A petition, however, was presented to the king by the Convention parliament in favour of him and Lambert, that they should be pardoned as to their lives, to which was returned a gracious answer. Nevertheless in July 1661, in the succeeding parliament, an order was framed by the house of commons, that Vane and others should be tried for the murder of Vane and others, and for other crimes, according to law. Upon this order Vane was brought from his prison in the Isle of Scilly, and committed to the Tower for trial. For his conduct after the death of Charles I, comprehending his active efforts in opposition to the present king, as a member of the council of state and a person in office, he was indicted of high-treason. In June 1662 he was put to the bar, and is said to have defended himself with ability and resolution, or, as his enemies say, with arrogance and insolence. Among other pleas, he urged that treason could only be committed against a king de facto, and not de jure, which was the situation of Charles II till the Restoration; and that he had in all changes adhered to the commons, as the fountain of all regal authority: a principle for which he had expounded himself to the tyranny of Cromwell, and for which he was now ready to undergo all the rigour of perverted law and justice. Nevertheless he was found guilty, and sentenced to suffer the whole penalty adjudged to high-treason, which, however, was commuted for beheading. It has been not unreasonably urged, that though the king could not safely be defended for breach of his promise to the former parliament on this occasion, his death was a retaliation for the part he had acted on the impeachment of Lord Strafford. On the 14th of June he was brought to the scaffold on Tower-hill, and though confi-
VAN
dered as a person possessing little natural courage, he be-
haved with wonderful composure and firmness. In his ad-
dress to the spectators, whilst he justified himself on certain
points that were construed to reflect upon the government
and judges, he was rudely interrupted by the lieutenant of
the Tower, who repeatedly ordered the trumpets to find
that his voice might not be heard. He died about the 50th
year of his age, and left one son. His writings, chiefly on
religious topics, were confused and obscure. Bishop Burnet
says of him, *that though he fat up a form of religion of his
own, yet it confined rather in a withdrawing from all other
forms, than in any new or particular opinions or forms,
from which he and his party were called 'Seekers,' and
seemed to wait for some new and clearer manifestations.
In those meetings he preached and prayed often himself, but
with so peculiar a darkness, that though I have sometimes
taken pains to see if I could find out a meaning in his
words, yet I could never reach it. His friends told me he
leaned to Origen's notion of an universal salvation of all,
both of devils and the damned, and to the doctrine of pre-
existence."

As to his political conduct, it is observed by one of his
biographers, that "though he employed craft and dissimula-
tion as his means, there seems no reason to doubt of his
frankness as to his ends, which appear to have been those of
a politician, but not of a selfish statesman. His enemies
carelessly charge him with mercenary views, and his friends
represent him as a real, though mistaken, lover of his country."

VANE, in a Ship, is a thin flip of bunting hung to the
mast-head, or some other conspicuous place, to shew the
direction of the wind. It is commonly fewed upon a
wooden frame, called the fcock, which contains two holes,
by which to flip over the spindle, upon which it turns about
as the wind changes.

VANE, Dog, in Sea Language, is a small light vane,
formed of a piece of packthread of about two feet in
length, upon which are fixed five or six thin slices of cork
fluke full of light feathers. It is ususally fastened to the
top of a staff, two yards high, which is placed on the top
of the ship's side, on the quarter-deck, in order to shew the
direction of the wind to the helmsman, particularly in a
dark night, or when the wind is extremely feeble. Falconer.

Vanes, or Mathematical Instruments, are ateged to
move and fide upon crosses, fo-called, fo-fo, fo-fo, fo-fo,
Vanes, or Fantes, of Feathers. See Feather.

Vanes, Weather. See Weather.

Vanes of Windmills. See Windmill.

Vaneering. See Venerering.

VAN-ELLEN, Justus, in Biography, was born at
Utrecht in 1685, and losing his father during the course of
his academical studies, he commenced the profession of an
author for a subsistence. His first work, published in 1711,
was entitled "Le Misanthrope," written after the model of
the English Spectator, which he continued till it amounted
to two vols. 8vo. To the "Literary Journal," established
by a society of young persons at the Hague in 1713, he was
a liberal contributor; and the profits were alluded to him.
The contributions to this Journal were examined by the
whole society, so that every article was sanctioned by the
judgment of the whole body. This was continued till the
year 1718, when Van-Elfen engaged in a new periodical
paper, entitled "Bagatelle, ou Dificours Ironiques," de-
gigned to ridicule the vices and follies of the time. This
publication failed of success. The author afterwards en-
gaged in various literary undertakings, and agreed to con-
tinue the " Nouvelles Litteraires," when the prince of 111.

Philippitahl, in 1719, took him as a companion in a journey
to Sweden. Of this tour he published an account in 1726,
in a second edition of his "Misanthropie." He afterwards
occupied himself in translations, chiefly from the English;
and at Leyden, where in 1724 he superintended the educa-
tion of a young man at the university, he undertook to
translate from Dutch to French Gerard Van Loon's "Mel-
dalick History of the United Provinces," but a dispute
occurring between him and the bookfellers, he finished only
two volumes. In 1725 he commenced a new periodical
work, under the title of "Nouveau Spectateur Francois," of
which twenty-nine sheets appeared. In 1727 he accom-
panycd the count of Welderen, ambassador from the States
to the court of London, as his secretary, when he wrote an
ode in French on the coronation of George II. In 1731
he began a work, entitled the "Dutch Spectator," and
continued it till the whole amounted to 12 vols. 8vo. Van-
Effen died in September, 1731, at Bois-le-Duc, where he
had for some years occupied the post of inspector of the
magazines. He sustained the character of an ingenious and

VANELLLOE, in Botany, See VANILLA.

VANELLUS, in Ornithology, a name given by many to
the lapwing, more commonly known by the name capella.

VANETTI, Clementino, in Biography, knight of the
holy Roman empire, and lord of Villanova, was born at
Roerdero in 1755, and being educated under the care of
his uncle, after the death of his father, he became, by in-
cently reading Plautus and Terence, so good a Latin
scholar, that, in his 16th year, he wrote a Latin comedy,
entitled "Lumpadaria," and, in the following year, recited
an inaugural oration in the Academy degli Agiati at Ro-
veredo, in the true language of Plautus. Before the age of
22, he was elected secretary of this Academy, and he had
improved his taste by a familiar acquaintance with the works
of Cicero. In 1776 he defended Tirabochi against the at-
tack of the Spaniard Serrano, for his censure of some paf-
fages in the epigrams of Martial; and the letter he publised
on this occasion, considered as the production of a young
man 23 years of age, was much admired. Upon the death
of his intimate friend, the abbé Zorzi of Venice in 1779,
he paid an honourable tribute of respect to his memory by
publishing his life, and a collection of letters that had passed
between them, and also an examination of a question sug-
gested by d'Alembert, whether any one at present should
venture to write Latin, which he decided in the affirmative.
But Vanetti's most humorous writing, in the Latin language,
was a bitter satire on Caggioiro, who deluded the people at
Roerdero, in 1788, by his pretended prophecies and miracles.
Vanetti, in order to expose this juggler, wrote a small work
in the manner of the book of Chronicles, and in the Latin
lyle of the Vulgate, entitled "Liber Memorialis de Caggio-
iro." Encouraged by Betinelli and others, he became a
classical writer in his native language, beginning with a
well-written life of the younger Pliny. But his chief fame
was derived from his "Observations on the Poems of Horace,
with Illustrations of that Poet," which, with respect to matter
and language, are laid to exceed any thing of the kind in
Italian. He also published fourteen dialogues in the manner
of Lucian: and having tried his talents in various kinds of
poetry, his "Sermon" in the true Horatian spirit are pre-
comment, and hence he obtained the name of the Italian
Horace. Besides the reputation which he acquired as a poet,
he also excelled in etching paintings. To the noise and
trifle of the world he preferred the tranquillity of domestic
life on his estate, which he compared to the Sabine farm of
Horace, and never travelled farther from home than Verona,
Manila,
Mantua, or Venice; and he died, universally lamented, in his native city, of an inflammation of the lungs, in the 40th year of his age. The abbé Lorenzi published at Roveredo, in 1799, "Commentarius de Vita et Scriptis Clementini Vanneti," from which the preceding account of him has been extracted. Gen. Biog.

VAN-EYCK. See Eyck.

VANGAC, in Geography, a river of the island of Luçon, which runs into the Chinese sea, N. lat. 18° 45′.

VANGEN, a town of France, in the department of the Lower Rhine; 9 miles S.E. of Saverne.—Allo, a town of Switzerland, in the canton of Berne; 4 miles E. of Solercure.

VANGIONES, VANGAC, and VANGAC, in Ancient Geography, a people of Belgic Gaul, and originally of Germany. According to Cluver, they were bounded on the north and east by the Rhine, on the south by the Nemetes, and on the west by the Mediomatrices.

VANGOLE, in Geography, a town of Hindoostan, in Coimbatore; 5 miles N. of Aravaxourche.

VAN-GOYEN, in Biography. See Goyen.

VANS, in Sea Language, are a sort of braces to support the mizen-gaff, and keep it steady. They are fixed on the outer end or peak, and reach downwards to the after part of the ship's side, where they are hooked and drawn up; so as to be flapped when the wind is fair; and drawn in to windward, when it becomes unfavourable to the ship's course. Falconer.

VANG-TCHOUANG, in Geography, a town of China, in Kiang-nan, on the river Hoang; 15 miles W.N.W. of Fong-yang.

VANGUERIA, in Botany, a barbarous and intolerable name, made by Commeron out of the Madagascar appellation of this plant, Voa-vanguer. Von Rohr called the same genus Vavanga; which Vahl has unwillingly adopted, expressing at the same time a wish, that he could have dedicated the genus to professo Wittmann. We should now have taken advantage of this wish, had there not already been a Vantium, which will appear in its proper place. Thus circumstanced, and without meaning, on this or any other occasion, to uphold such names, except for reprobation, we for the present here introduce Vangueria.—Juff. Gen. 260. Wild. Sp. Pl. v. 1. 976. Poir. in Lamarck Dict. v. 8. 331. Lamarck Illust. t. 159. Venten. Tabl. 586. Jacq. Hort. Schoenbr. v. 1. 20. (Vavanga; Vahl T. 207.)—Clados and order, Pentandria Monogynia. Nat. Ord. Rubiaceae. Juff.

Gen. Ch. Cal. Perianth superior, of one leaf, with five spreading, somewhat reflexed, permanent teeth. Cor. of one petal; tube bell-shaped, twice the length of the calyx, closed at the upper part with erect hairs; limb in five deep, ovate, acute, equal, spreading, at length reflexed, segments, rather shorter than the tube. Stam. Filaments five, awl-shaped, very short, inserted between the segments of the corolla; anthers heart-shaped, pointed, incumbent. Pfbl. German inferior, turbinate; style awl-shaped, rather longer than the tube, inclining to one side; stigma thick, obtuse, furrowed, two-ridged. Peric. Berry globose, coriaceous, with a furrow at the top, containing four or five seeds, imbedded in pulp. Sede elliptical, compressed, with a lateral scar, and a small incomplete tunic, of two membranous, lanceolate, falcate valves, attached to the scar.

1. V. edulis. Madagascar. Medlar. Wild. n. 1. Vahl Symb. v. 3. 36. (V. Commeronii; Jacq. Hort. Schoenbr. v. 1. 20. t. 44. Vavanga edulis; Vahl Tr. of Nat. Hist. Soc. of Copenb. v. 2. pl. 1. 208. t. 7.)—Gathered in the island of Bourbon, by Commeron, whose specimens are before us. Cultivated in Guadaloupe and Santa Cruz, for the sake of its cattable fruit. Von Rohr, who communicated this plant to professor Vahl, thought it a native of China, but Commeron was told it came from Madagascar, and was there called Voa-vanguer, or Voa-wangi. Jaquetin mentions it as flowering every year in the stoe of Schoenbron, but never ripening fruit. The stem is shrubby, fix feet, or more, in height, with round, smooth, opposite branches, slightly quadrangular when young. Leaves opposite, on short stalks, deciduous, elliptical, acute, entire, smooth, five or six inches long, and two or three broad, with one central rib, and many transverse ones connected by reticulated veins; paler beneath. Stipular intralocular, triangular, pointed, in pairs connected at the base, embraces the branch above the footstalks, and much resembling those of Stereobay. Pannus lateral, opposite, cymose, many-flowered, downy, much shorter than the leaves, springing from between the insertion of last-year's footstalks. Flowers greenish-yellow, smaller than any of the valley, frequently four-cleft. Fruit the size of a large gooseberry, with a leathery, or somewhat flaccid, coat.

VANHALL, John, in Biography, an instrumenal composer of great and original genius, was born at Vienna in 1740. We know not what he had published previous to his symphonies, which were composed in 1767, and soon circulated in MS. all over Europe. The duke of Dorset, we believe, first brought them to England about the year 1771. Several excellent symphonies of the Manhein school had been previously published by Bremner, which introduced us very agreeably to the new style of German symphony founded by the elder Stamitz; but till we were acquainted with the symphonies of Haydn, the spirited, natural, and unaffected style of Vanhall excited more attention at our concerts than any foreign music which we had imported for a long time. They were admirably played at the Pantheon concerts, when led by La Motte, Giardini, and the elder Cramer. He composed too much perhaps, and for too great a variety of instruments; but his symphonies, quartets, and other productions for violins, certainly deserve a place among the first productions, in which unity of melody, pleasing harmony, and a free and manly style are preferred. VanHuyssen. See Huyssen.

VANI, a name of the Hindoo goddess Sarâ/wâti; which see. This name is also given to Agni or Pavaka, regent of fire; when, however, it is usually written Vahni.

VANI, Cape, in Geography, a cape on the N. coast of the island of Milo. N. lat. 36° 46′. E. long. 24° 20′.

VANIAMBADDY, a town of Hindoostan, in Myforie; 112 miles E. of Seringapatam. N. lat. 12° 41′. E. long. 78° 45′.

VANNEMSOAR, a town of Hindoostan, in Godda; 21 miles S.W. of Damapatia.

VANIERE, James, in Biography, a learned Jesuit, was born in 1664, at Causses, in the diocese of Beziers, Languedoc, and having studied at the Jesuits' college at Beziers, entered into the society in 1682. His poetic talents were exhibited by two pieces, one entitled "Stagna," during his regency at the college of Tournon; and another entitled "Columbia," at Toulouse: and his character as a poet was established by his "Praedium Rufficum," in fifteen books, on the subject of a farm, in imitation of Virgil's Georgics. The most complete edition of this work is that of Paris, in 1756. Vaniere was successively professor and rector in the schools of his order at Montpelier, Toulouse,
and Auch, and died at Toulouse in 1739. His other works were a volume of "Opuscula," consisting of eulogies on moral topics, epistles, odes, epigrams, &c.; a "Dictionary of Poetry," in Latin, quarto, a work in high estimation, and abridged for the use of students; and a "Dictionary, Latin and French," which he began, but did not live to finish. For his encouragement in his studies, the king allowed him a pension. Moreri. Nouv. Dict. Hift. Gen. Biog.

VANERIA, in Botany, received its name from Loureiro, in memory of father James Vanier, a French Jesuit, who was born in 1664, and died in 1739; celebrated for a poem on rural life, in which various plants are beautifully described. — Loureiro. Cochinch. 564.—Clasf and order, Monocia Pentandria. Nat. Ord. Ursica. Juff.

Gen. Ch. Male, Cal. Perianth inferior, of three nearly direct, lanceolate, equal, coloured leaves, deciduous. Cor. Petals two, lanceolate, of the size and colour of the calyx. Nectar a lip, proceeding from the lower part of the style, con- voluted at the base, dilated at the margin, without a spur, falling off with the petals. Stam. Another a hemispherical, movable, terminal, deciduous lid, of two cells, attached by its posterior edge to the top of the style; masses of pollen globular, granulated. Pfr. Cor. inferior, elongated, nearly cylindrical, style erect, semicylindrical; stigma convex, towards the top of the style, in front. Peric. Capsule elongated, slightly triangular, effuse, of one cell. Seeds very numerous, lenticular, dehiscing of a tuft, imbedded in pulp.

1. V. aromatica. Aromatic Vanilla, Vanilla, or Vanilla. Willd. n. 1. Ait. n. 1. (V. flore viridi et albo, fructu nigricante; Plunt. Ic. 183. t. 188. V. maxima; Merian. Surin. t. 25. Epidendrum Vanilla; Linn. Sp. Pl. 1347.) Leaves ovate-oblong, ribbed. Calyx and petals undulated. Lip acute. Capsule nearly cylindrical, very long.—Native of South America. Stem parithical, climbing by means of simple, effuse, fibrous, solitary radicles from each joint. Leaves a span long, succulent, as thick as those of houseleek. Flowers large, variegated with green and white. Fruit eight or ten inches long, acquiring, after it is gathered, a peculiar and delicious fragrance, like the flowers of Orchis nigra, and some others of that family; on which account the Vanilla is used to perfume chocolate, and becomes a valuable article of commerce.

2. V. angififlua. Narrow-leaved Japan Vanilla. Willd. n. 2. (Epidendrum Vanilla ?; Linn. Sp. Pl. 1348. Angurak. Warna; Kempf. Amon. 867. t. 569. f. 2.) Leaves linear-lanceolate. Calyx and petals flat. Lip acute.—Native of Japan. By Kempfer's account this is a parithical climber like the last, and agrees with that in the colours of its flower, except being dotted with purple. Nothing is said concerning the fruit.

3. V. clamensata. Tendril-bearing Vanilla. Swartz Ind. Occ. 1515. Willd. n. 3. (Cereus affinis feraeiss planta aphylla, &c.; Sloane Jam. v. 2. 160. t. 244. f. 3. 4.) Leaves lanceolate, acute, concave, rigid, recurved. Calyx and petals flat. Capsules somewhat triangular.—Native of woods, on a very dry calcareous soil, in the mountainous inland parts of Jamaica, Hispaniola, &c. flowering in July. It is vulgarly called Green-wth, and the negroes use a decoction of the whole plant for syphilitic complaints. The stem climbs to the height of twenty or thirty feet, and is covered, as it joined, at the infection of each leaf, and tendril-like radicles. Leaves fleshy, an inch long. Flowers large, white, in axillary clusters. Fruit long and large, fleshy, with black fuming seeds. Swartz. The figure of the flower in Swartz's plate belongs to this species.

4. V. planifolia. Fragrant Vanilla. Ait. n. 2. Andr. Repuf. t. 538. (Myobroma fragrans; Salib. Parad. t. 82.)—Leaves oblong-lanceolate, flat, slightly reticulated. Calyx and petals even. Lip fringed, abrupt.—Native of the Well Indies, said to have been introduced into our flowers by the present duke of Marlborough. In July this rivals the first species, but the leaves are not so thick; the calyx and petals are not undulated, nor the lip pointed. We have no account.
account of the fruit. The flowers are said to be very fragrant, especially at night. Mr. Salisbury is erroneously charged, in Andrew's work, with having confounded this and the *V. aromatica*.

The species of this genus are far from being all known or understood.

The plant which produces the fruit called *vanilla* or *branilla* by the Spaniards, or the *epidendrum vanilla* of Linnaeus, has a trailing stem, somewhat like the common ivy, but not so woody, which fastens itself to any tree that grows near it by small fibres or roots produced at every joint; these attach themselves to the bark of the tree; and by them the plants are often nourished, when they are cut or broken off, from the root, at a considerable height from the ground, as is the case with the ivy in England. The leaves are as large as those of the common laurel, and are produced alternately at every joint. It rifes to the height of eighteen or twenty feet, and the flowers are of a greenish-yellow mixed with white, which, when fallen, are succeeded by the fruit, which is eight or ten inches long.

The fruit which is manufactured, grows not only in the bay of Campeachy, but also at Carthagena, at the Carareas, Honduras, Darien, and Cayan, at all which places the fruit is gathered and preferred; but it is rarely found in any of the English settlements, though it might be easily propagated in them. For the flowers are so full of juice, that they will continue fresh, out of the ground, for several months.

When these plants are intended for propagation in the warm parts of America, nothing more is required than to make cuttings of three or four joints in length, which should be planted close to the stems of trees in low marshy places, and the ground about them kept clear of weeds.

The method used to preserve the fruit is, when it turns of a yellow colour, and begins to open, to gather it, and lay it in small heaps to ferment two or three days, in the same manner as is practised for the cocoa pods; then they spread them in the sun to dry, and when they are about half dried, they flat them with their hands, and afterwards rub them over with the oil of palma Chrifli, or of the cocoa; then they expose them to the sun again to dry, and afterwards they rub them over with oil a second time; then they put them in small bundles, covering them with the leaves of the Indian reed to preserve them. These plants produce but one crop of fruit in a year, which is commonly ripe in May, fit for gathering, for they do not let them remain on the plants to be perfectly mature. When they are about half changed yellow, they emelf them better for keeping than when thoroughly ripe; at which time the fruit splits. While the fruit is green it affords no remarkable scent, but as it ripens it diffuses a most grateful aromatic smell; but when it begins to open, the birds attack them, and devour the seeds greedily.

The fruit which is brought to Europe is of a dark-brown colour; wrinkled on the outside, and full of a vast number of black seeds, like grains of sand, of a pleasant smell, like balsam of Peru.

This fruit is only used in England as an ingredient in chocolate, to which it gives an agreeable flavour to some palates, though it is disagreeable to others; but the Spanish physicians use it in medicine, and emelf it grateful to the stomatch and brain, good for expelling wind, for provoking urine, refifting poifon, and curing the bite of venomous animals. Miller's Gard. Dict.

The *vanillas*, or *vanilloes*, have an unaccountable aromatic taste, and a fragrant smell, like that of some of the finer balsams heightened with mufk. They are used chiefly in perfumes: scarcely ever among us in any medical intention: though they should seem to derive a place among the principal medicines of the nervous elafos. By distillation, they impregnate water strongly with their fragrance, but give over little, or nothing with pure spirit. By digestion, spirit totally cxtracted by them is not taken off by mufk, nor does it produce a very agreeable taste; but if mildly diluted with it, it acquires a pleasant aromatic quality.
his writings were as aburf or blasphemous as to entitle him to the character of a defisher of God and religion." An Apology for Vanini was published in Holland in 1712, by Peter Frederick Arp, a learned lawyer. Moreri. Molhein, vol. v.

**VANISHERING FRACTIONS**, are fractions in which, by giving a certain value to the variable quantity or quantities entering into them, both numerator and denominator become zero, and consequently the fraction itself is then $\frac{0}{0}$.

The idea of fractions of this kind first originated about the year 1702, in a contest between Varignon and Rolle, two French mathematicians of some eminence, concerning the principles of the differential calculus, of which the latter was a firenous opponent; and among other arguments against the truth of the doctrine which had then been recently introduced, he proposed an example of drawing a tangent to a certain curve, at the point where the two branches intersect each other; and as the fractional expression for the subtangent, according to that method, had both its numerator and denominator equal to zero, or $\frac{0}{0}$, he regarded such a result as aburf, and adduced it as a proof of the fallacy of this mode of solution. But the mystery was soon after explained by John Bernoulli; and upon a renewal of the dispute, still farther by Saurin, who showed that the fraction in the case here mentioned had a real value. These fractions were also the cause of a violent controversy between Waring and Powell in 1762, when these gentlemen were candidates for the mathematical professorship at Cambridge: Waring maintaining that the fraction $\frac{x^3 - a^3}{x - a}$, when $x = 1$, is equal to $4$; and Powell, or rather Maferer, who is commonly supposed to have conducted the dispute on the part of the latter, that it was equal to $0$, or indeed that it could have no value whatever; and it must be acknowledged that the fame difference of opinion relative to this kind of fractions still exists in all its force. Woodhouse, in his "Principles of Analytical Calculation," in treating of these quantities, after assuming the simple case of $\frac{x^3 - a^3}{x - a}$ to find the value of it, when $x = a$, observes, that the signification of this expression is, that $x^3 - a^3$ is to be divided by $x - a$, and the result of that division is $x + a$, or putting $x = a$, it becomes $a + a$, or $2a$. This result, however, he remarks, is no direct and natural consequence arising from the principles of calculation, but, on the contrary, it is a result arbitrarily obtained, by extending a rule, and observing a certain order in the processes of calculation.

To the question, what does $\frac{x^3 - a^3}{x - a}$ become when $x = a$; the obvious and logical answer is $x^2 + ax + a^2$, and the question is, whether in this form it will admit of any further reduction. It is true, if we operate upon this quantity according to the rules laid down in other apparently similar cases, we obtain $\frac{x^2 - a^2}{x - a} = x + a = 2a$; but here is evidently an extension given to a rule beyond what was first intended; for this rule was instituted for operating on real quantities, whereas in this case we have employed it on quantities having no value whatever, being in fact the division of $0$ by $0$, for which abstruseuly no rule can be given. This, however, is not a case peculiar to these fractions. It is to the fame source we must attribute the introduction of the negative symbol, and all the mysteries attendant upon it, as well as to every kind of imaginary quantity.

In vol. i. p. 219, of Bonnycafe's Treatise of Algebra, we have the following rule for finding the value of vanishing fractions.

1. If both the terms of the given fraction be rational, divide each of them by their greatest common measure; then, if the hypothesis which is found to reduce the original expression to the form $\frac{0}{0}$ be applied to the result, it will give the true value of the fraction under consideration.

2. When any part of the fraction is irrational, observe what the unknown quantity is equal to, when the numerator and denominator both vanish, and put it equal to that quantity $+ i$; then if this be substituted for the unknown quantity, and the roots of the surds be extracted to a sufficient number of places, the result, when $i$ is put equal to $o$, will give the true value of the fraction. From which rule the author obtains the following results: 

1. $\frac{x^3 - a^3}{x - a} = 2a$, when $x = a$.
2. $\frac{b(x - \sqrt[2]{ax})}{x - a} = \frac{1}{2} b$, when $x = a$.
3. $\frac{x^n - a^n}{x - a} = m a^{n-1}$, when $x = a$.

See Bonnycastle's Algebra, Woodhouse's Principles of Analytical Calculation, and Barlow's Dictionary.

**VANISHERING FRACTIONS**, are fractions in which, by giving a certain value to the variable quantity or quantities entering into them, both numerator and denominator become zero, and consequently the fraction itself is then $\frac{0}{0}$.

The idea of fractions of this kind first originated about the year 1702, in a contest between Varignon and Rolle, two French mathematicians of some eminence, concerning the principles of the differential calculus, of which the latter was a firenous opponent; and among other arguments against the truth of the doctrine which had then been recently introduced, he proposed an example of drawing a tangent to a certain curve, at the point where the two branches intersect each other; and as the fractional expression for the subtangent, according to that method, had both its numerator and denominator equal to zero, or $\frac{0}{0}$, he regarded such a result as aburf, and adduced it as a proof of the fallacy of this mode of solution. But the mystery was soon after explained by John Bernoulli; and upon a renewal of the dispute, still farther by Saurin, who showed that the fraction in the case here mentioned had a real value. These fractions were also the cause of a violent controversy between Waring and Powell in 1762, when these gentlemen were candidates for the mathematical professorship at Cambridge: Waring maintaining that the fraction $\frac{x^3 - a^3}{x - a}$, when $x = 1$, is equal to $4$; and Powell, or rather Maferer, who is commonly supposed to have conducted the dispute on the part of the latter, that it was equal to $0$, or indeed that it could have no value whatever; and it must be acknowledged that the fame difference of opinion relative to this kind of fractions still exists in all its force. Woodhouse, in his "Principles of Analytical Calculation," in treating of these quantities, after assuming the simple case of $\frac{x^3 - a^3}{x - a}$ to find the value of it, when $x = a$, observes, that the signification of this expression is, that $x^3 - a^3$ is to be divided by $x - a$, and the result of that division is $x + a$, or putting $x = a$, it becomes $a + a$, or $2a$. This result, however, he remarks, is no direct and natural consequence arising from the principles of calculation, but, on the contrary, it is a result arbitrarily obtained, by extending a rule, and observing a certain order in the processes of calculation.

To the question, what does $\frac{x^3 - a^3}{x - a}$ become when $x = a$; the obvious and logical answer is $x^2 + ax + a^2$, and the question is, whether in this form it will admit of any further reduction. It is true, if we operate upon this quantity according to the rules laid down in other apparently similar cases, we obtain $\frac{x^2 - a^2}{x - a} = x + a = 2a$; but here is evidently an extension given to a rule beyond what was first intended; for this rule was instituted for operating on real quantities, whereas in this case we have employed it on quantities having no value whatever, being in fact the division of $0$ by $0$, for which abstruseuly no rule can be given. This, however, is not a case peculiar to these fractions. It is to the famous source we must attribute the introduction of the negative symbol, and all the mysteries attendant upon it, as well as to every kind of imaginary quantity.

In vol. i. p. 219, of Bonnycafe's Treatise of Algebra, we have the following rule for finding the value of vanishing fractions.

1. If both the terms of the given fraction be rational, divide each of them by their greatest common measure; then, if the hypothesis which is found to reduce the original expression to the form $\frac{0}{0}$ be applied to the result, it will give the true value of the fraction under consideration.

2. When any part of the fraction is irrational, observe what the unknown quantity is equal to, when the numerator and denominator both vanish, and put it equal to that quantity $+ i$; then if this be substituted for the unknown quantity, and the roots of the surds be extracted to a sufficient number of places, the result, when $i$ is put equal to $o$, will give the true value of the fraction. From which rule the author obtains the following results: 

1. $\frac{x^3 - a^3}{x - a} = 2a$, when $x = a$.
2. $\frac{x - x^3}{1 - x} = 4$, when $x = 1$.
3. $\frac{b(x - \sqrt[2]{ax})}{x - a} = \frac{1}{2} b$, when $x = a$.
4. $\frac{x^n - a^n}{x - a} = m a^{n-1}$, when $x = a$.

See Bonnycastle's Algebra, Woodhouse's Principles of Analytical Calculation, and Barlow's Dictionary.
complished and elegant woman, and we never heard any thing more pleasing than her performance.

VAN-MALDER, concert-matter and chamber-musician to prince Charles at Brussells, and leader of the band at that theatre; a composer of spirited and pleasing symphonies, which were long in favour at our national theatres. He composed a comic opera, "La Bagarre," 1754, for the Italian theatre at Paris, and died at Brussells in 1771.

VAN-MANDER, a painter and author, was born at Meulebeke, near Courtray, in 1548, of a noble family, and received an education fitted to his rank. His talents developed themselves at an early period of his life, and particularly a disposition to painting; and he was placed under the tuition of Lucas de Heere; afterwards he became a disciple of Peter Vlrick, an historical painter of some eminence at Courtray, and finished his education in art by a journey to Italy, where he studied for three years. From thence, after painting several pictures, he went to Vienna, accompanied by Spranger, whose friendship he had cultivated, and there received a preening invitation to enter the service of the emperor; but love for his native country prevailed, and thither he returned. He then experienced much encouragement, and was in possession of full employment, when the wars in the Low Countries prevented his enjoyment of it. He took refuge in Haerlem, and there with Goltzius founded an academy. Van-Mander united with the talents of a painter that of a poet, and composed tragedies and comedies, several of which were acted with success, with decorations painted by himself; and we are indebted to him for a very useful history of the painters of antiquity and of his own country. He died at Amsterdam, in 1606.

VANNIEUS, Lat. VANNIE, STEFFANO, Ital., the name of an Augustine monk, born at Ricinati, a small town in the March of Ancona and Ecclesiastical State, was music director at Afoli, who published at Rome in 1553, small folio, a mot moleant treatise on music, in which he has inserted all that preceding books on the subject contained. There is nothing that was new in this at the time of its publication; but no one book then published contains half its contents. Walther has given a long list of the divisions and subdivisions of this work, which is written in Latin, and which, perhaps, is all that will ever be read by those who may obtain possession of the book, which is now become very scarce.

VANNE, in Geography, a river of France, which runs into the Yonne, near Sens.

VANNES, a small island in the North Sea, on the coast of Norway. N. lat. 70° 10'. E. long. 197° 44'.

VANNES, a sea-port town of France, and capital of the department of the Morbihan, at the union of the two small rivers, which form a harbour in the lake Morbihan; before the revolution, the fee of a bishop. The principal commerce is in corn, bar-iron, and fish. It has two suburbs, one of which is larger than the town itself. In 1800, the royalists, under Georges, were defeated by the republicans, under Brun; 13 posts N.W. of Nantes. N. lat. 47° 30'. W. long. 2° 40'.

VANNES, Lat., a town of France, in the department of the Ardèche; 6 miles S.W. of Joyeuse.

VANNI, FRANCESCO, Cavalier, in Biography, was the son of a painter of little celebrity at Vienna, who died whilst he was very young, and was born in 1563. He went to Rome when he was about fifteen, and entered the school of Giovanni de Vecchi, and became an imitator of Baroccio. He also went to Parma to draw from the fame fount as Baroccio, viz. the works of Corregio and Parmigianino. He was invited to Rome to aflit in adornning St. Peter's, and there he painted his Simon Magus, which yet, though much injured, attests his capacity. For this performance Clement VIII., con$idered appro priate, the order of Christ. He also painted several other pictures for public edifices in that city; but his best performances are at Sienna, as his Marriage of St. Catharine, in the church of II Refugio; and S. Raimondo walking on the Sea, in the Dominicans; which is considered the finest work in the city. He died at Sienna in 1610, at the age of forty-seven, leaving a son, Rafaelle Vanni, then only thirteen, who afterwards became a painter, and imitated the works of Pietro Cortona. He became a member of the academy of St. Luke in 1655.

VANNICUM REGNUM, in Ancient Geography, a kingdom of European Sarmatians, according to Phny. Tacitus reports that it was the kingdom of Vannius, which Drufus allotted as a portion to the Sueans, when he fixed their abode on the Danube, between Marus and Cufus.

VANNING-SHED, among Miners, an instrument used for washing the ores of any metal, after being reduced to powder, by which to discover the richness and other qualities of the ore. See SHED, Tin, and VAN.

VANNUCCI, in Biography. See Andrea del Sarto, and Perugina.

VAN-ORIOT. See Oriot.

VAN-OOST. See Oost.

VAN-ORLAY. See Orlay.

VAN-OSTADE. See Ostade.

VANQUISH, a disease in sheep, which has often the titles of pinning and daifing given to it by shepherds.

It is describ'd as most fierce among young sheep by fome, and as, in a great measure, confined to fome particular districts in the western portion of the north part of the island, where the land is very clofe, hard, dry, and heathery. It is laid that it constantly fixes on the belly of the flock, and that although they continue to feed moft greedily, they daily pine away to a mere skeleton. But that it is fortunately not a difeafe that is attended with great danger, as on removing them to soft gravy pastures, especially such as have been recently limed, they almost immediately recover, and never fail, in future, to become excellent and healthy animals. So far as regards the gradual wasting of the animal, this disease has some reemblance to the rot in its nature and caufe; it is directly the reverse:—that it arises from an excess of moifure, is a diseafe of debility, and is charaeterized by extreme thinness of the blood; while in this, or the vanquish, on the contrary, the condition of the animal is too high, its blood too thick, and its paffure too arid, dry, and parched.

Others, however, describe it in so different a manner, that it fearcely appears to be the fame diseafe. On peat-mofs lands much exposed to the north-eaft, in cold moifit feaons, where fheep-farmers have not the command of drier fonder pastures, on which the fheep can be turned in the autumn and winter months, the young fheep are liable to be attacked by the vanquish, which confines them entirely away. This malady has its feat, as is fuppofed by praetical fhepherd's, chiefly in the blood and bones: but it feems, in a little time, to spread over the whole fytem, which becomes debilitated and emaciated. Cold and moifure are laid to aflit in bringing it on, and also to aggravate the appearances; but the principal fault, it is believed, is in the mofty land. The mofses become the earliest common pastures for fheep in these places in the spring feaon, but fome part of the food they fupply is dry, wiry, and unpalatable, and the heath lefs kindly and grateful.
grateful to the sheep than that on dry moory land on gravel, being often scanty, woody, and rigid. The excess of moulder, too, in them may probably, it is thought, affect the qualities and healthiness of the heat, as food for sheep. Besides, there is in such mossey a greater proportion of the crofs-leaved fern than is found on dry sheep-walks; and it is thought by many that sheep do not relish it so well as the common kind, when the shoots are young.

From these accounts, it would seem that the true nature of the complaint is not yet well understood, but it is probably some defect in the lachet organs, by which a due supply of nourishment is prevented from being taken up, the consequence of which is a rate of atrophy and emaciation in the animal.

The remedies which have been chiefly depended upon in these cafes by sheep-farmers, are those of either removing the sheep into fresh grassy lands, or the change of them from the peaty pasture to one that is sweet and dry, during the autumn and winter. The latter, it is said, not only proves a cure of the disease, but wholly prevents it. In some cafes, medicines of the mild stimulating balsamic kind might perhaps be used with benefit.

VANS, les Dames, or Vanaut, in Geography, a town of France, in the department of the Marne; 12 miles N.E. of Vincennes le Franc.

VANSIRE, in Zoology, a species of weasel with short ears; the hair brown at the roots, barred above with black, and ferruginous; the tail of the same colour; the length from nine to about fourteen inches, and the tail nearly ten. This animal inhabits Madagascar.

VANSOMER, Paul, in Biography, a portrait painter, born at Antwerp in 1576: he for a while resided at Amsterdam, and with his brother Bernard practised his art there with success. About 1605 or 1606, he visited England, and was very much employed there; as many of his portraits are to be found in the houses of our nobility. He had the honour to be employed to paint king James I., and his queen, Anne of Denmark. He died at about the age of 45, and was buried in St. Martin's, as appears by the register, January 5, 1621.

VANSTOWN, in Geography, a town of the Cherokees, on the river Alabama.

VAN-SWIETEN, in Biography. See Sweieten.

VANT, or Vaunt. See Van.

VANTANEA, in Botany. Juss. 434; a name of Aublet's, which Schreber, according to correct rule, could not retain. See Lemsicia.

VANT-CHIN, in Geography, a city of China, of the second rank, in Quang-hi; 1147 miles S.S.W. of Peking. N. lat. 23° 17'. E. long. 106° 51'.

VAN-TIEN, a city of China, of the second rank, in Yen-nan; 1295 miles S.W. of Peking. N. lat. 24° 29'. E. long. 109° 14'.

VAN-UDEN, Lucas, in Biography, a landscape painter, born at Antwerp in 1595. He was principally his own instructor, and cultivated his talents by an allidious attention to nature, and studying the landscapes of Rubens, whom he imitated, and who employed him to paint on the back grounds of his pictures; which he did with so much conueniency of stile, that they appear to be the work of the same hand. He lived to the age of 65. He had a brother, Jacques Van-Uden, also a landscape painter, but inferior to him.

VANEY, in Geography, a town of France, in the department of the Côte d'Or; 6 miles E.S.E. of Châtillon-sur-Scorre.

VANZE, a town of Naples, in Basilicata; 10 miles S.E. of Venosa.

VAPINCUM, in Ancient Geography, Gap, a town of Gallia Narbonensis, between Caturiga and Alabons.

VAPORARIUM, or Vaporsomum Balneum, Vapour-Bath, in Chemistry, a term applied to a chemist's bath, or heat, in which a body is placed, so as to receive the fumes of boiling water.

The balneum vaporsum consists of two vessels, disposed over one another in such manner, as that the vapour raised from the water contained in the lower, heats the matter enclosed in the upper.

The vapour-bath is very commodious for the distilling of odiferous waters, and the drawing of spirit of wine. On this subject, see Bath, in Chemistry.

We also use the term vapour-bath, when a good perfume is made to receive the vapours arising from some liquid matter placed over a fire.

Many contrivances have been proposed for this purpose; and their expediency and utility are best known to those who are conversant in this business. See Aquaeus Bathis.

VAPORIZATION, Vaporation, in Chemistry, a term applied to the action of a fume, or vapour.

Vaporation is a kind of bathing, or rather of fomentation, by which the warmth, or humidity, of a vapour is made to act on some other body, that is to be warmed or moistened.

VAPORSUM BALNEUM. See Vaporation.

VAPOUR, Vapor, in Meteorology, a thin vehicle of water, or other humid matter, filled or inflated with air; which, being rarefied to a certain degree by the action of heat, ascends to a certain height in the atmosphere, where it is suspended, till it returns in firme of rain, snow, or the like. An assemblage of a number of particles, or vehicles of vapour, constitutes what we call a cloud.

Some ufe the term vapour indifferently, for all fumes emitted, either from moil bodies, as fluids of any kind; or from dry bodies, as sulphur, &c. But sir Isacc Newton, and other authors, better distinguished between humid and dry fumes, calling the latter exhalations.

For the manner in which vapours are rafed, and again precipitated, see Cloud, Dew, Rain, Barometer, and particularly Evaporation and Meteorology.

We shall here add, with refpect to the principles of solution adopted to account for evaporation, that Dr. Halley, about the beginning of the last century, seems to have been acquainted with the folvent power of air on water; for, he fays, that, supposing the earth to be covered with water, and the fun to move diurnally round it, the air would of itself imbibe a certain quantity of aqueus vapours, and retain them like fatts dissolved in water; and that the air, warmed by the fun, would fufpend a greater proportion of vapours, as warm water will hold more dissolved fatts; which would be discharged in dew, analogous to the precipitation of fatts on the cooling of liquors. Phil. Traf. Abr. vol. ii. p. 127.

Mr. Ecles, in 1755, endeavoured to account for the action of vapours and exhalation, and their fuppofition in the atmosphere, by means of the electric fire. The fun, he acknowledges, is the great agent in detaching vapours and exhalations from their maffes, whether he acts immediately by himself, or by his rendering the electric fire more active in its vibrations; but their subsequent action he attributes entirely to their being rendered specifically lighter than the lower air, by their conjunction with electrical fire: each particle of vapour, with the electrical fluid that surrounds it, occupying a greater space than the same
weight of air. Mr. Eeeles also endeavours to shew, that the
acet and deficient of vapour, attended by this fire, are the
cause of all our winds, and that they furnish a satisfactory
solution of the general phenomena of the weather and
barometer. (Phil. Trans. vol. xix. p. 124, &c.) Dr.
Darwin, in 1757, published remarks on the theory of
Mr. Eeeles, with a view of confuting it; and attempted
to account for the acet of vapours, by considering the
power of expansion which the constituent parts of some
bodies acquire by heat, and also that some bodies have a
greater affinity to heat, i. e. acquire it sooner, and retain it
longer than others. On these principles, he thinks, it is very
intelligible how water, whose parts appear from the coloip
to be capable of immense unfavourable expansion, should by heat alone
become specifically lighter than the common atmosphere.
A small degree of heat is sufficient to detach or raise the
vapour of water from the mafs to which it belongs; and
the rays of the sun communicate heat only to those
bodies by which they are refracted, reflected, or obfected,
whence, by their impules, a motion or vibration is caufed in
the parts of such bodies. Hence he infers, that the fpheres
circles of vapour will, by refracting the polar rays, acquire a
confant heat, though the surrounding atmosphere remain
cold. If it be asked, how clouds are supported in the
abence of the fun? it must be remembered, that large
mafs of vapour must for a confiderable time retain much of
the heat they have acquired in the day; at the fame time
reflecting, how small a quantity of heat was neceffary to
raise them, and that doubleles even a lefs will be sufficient
to fupport them; as from the diminished preffure of the
atmosphere at a given height, a lefs power may be able to
continue them in their present rate of rarefaction; and
afterly, that clouds of particular fhares will be fatisfied or
clevated by the motion they acquire from winds. Phil.
Trans. vol. i. p. 245.
For the effeét of vapour in the formation of springs, &c.
See SPRING and RIVER.
The quantity of vapour raised from the sea by the
warmth of the sun, is far greater than one would imagine.
Dr. Halley has attempted to effimate it. The refult of
his estimate is contained in the following articles.

1. That water falted to about the fame degree as salt-
water, and exposed to a heat equal to that of a funner's
day, did, from a circular surface of about eight inches
diameter, evaporate at the rate of six ounces in twenty-four
hours. Whence, by a calculs, he finds that the thick-
nets of the pellicle or fkin of water, evaporated in two
hours, was the fifty-third part of an inch; but, for a round
number, he fupposes it only a fixieth part; and argues thence,
that if water as warm as the air in funner evap-
orates the thicknets of one-fifteenth part of an inch in two
hours, from its whole surface; in twelve hours it will
evaporate the tenth of an inch; which quantity, he ob-
serves, will be found abundantly fufficient to furnish all the
rains, fprings, dew, &c. See RIVER.

In effet, on this principle, every ten square inches of the
surface of the water yield in vapour per dem a cubic
inch of water; and each square foot half a wine pint;
even an fpace of four feet square, a gallon; a mile square,
694 tons; and a square degree of fifty-nine English miles
will evaporate 33 millions of tons a day; and the whole
Mediterranean, computed to contain 160 square degrees, at
leaff 5280 millions of tons. Phil. Trans. No 189, or Abr.
vol. ii. p. 108, &c. See RIVER.

2. A surface of eight square inches, evaporated purely
by the natural warmth of the weather, without either wind
or fun, in the course of a whole year, 16,292 grains of water,
or fixy-four cubic inches; consequently the depth of water
thus evaporated in one year amounts to eight inches. But
this being too little to aulter the experiments of the French,
who found that it rained nineteen inches of water in one
year at Paris; or those of Mr. Townley, who found the
annual quantity of rain in Lancashire above forty inches;
he concludes that the fun and wind contribute more to
evaporation than any internal heat or agitation of the
water.

It has fince been discovered, that there was a fource of
error in Mr. Townley's experiments, with which the world
was not at that time ac quainted: his rain-gauge was fixed
in ten yards above the furface of the earth; but Dr. Herberden
has found, that a rain-gauge fixed below the top of a houfe,
received above a fift part more rain than another of the
fame fize above the top of the fame houfe; and that there
fell upon Weftminifter Abbey not much above one-
half of that which fell in the fame space below the tops of
the fplying houses. Experiments made by Dr. Dob-
fon of Liverpool, it appears, that the quantity of rain re-
ceived in a veffel placed on the ground exceeded that re-
ceived by another of the fame dimensions eighteen yards
higher than one-third, and lefs than one-half. Phil.
Trans. vol. lix. art. 47. and vol. lixii. art. 13. p. 256. See
RAIN.

With regard to the caufe of this difference, it may be
oberved, that as in chemical precipitations a greater
portion of the precipitating substance will be received on the
real bottom of a veffel containing the folution than on a
foppofed falle bottom placed any where above it, and that
in proportion to its height above the real bottom; fo a
greater quantity of water, confidering rain as a precipitation
of water before difolved in air, ought, on parting with its
former solvent, to fall on the furface of the earth than on an
imaginary horizontal plane of the fame dimensions above it;
and though the cafes are not exactly parallel, yet the
drops of rain in their defcent muft be somewhat increafed
either in number or fize; partly by fuccedively impinging
on the aqueous particles contained in the air through which
they pass, and by attracting others in virtue of their being
poifoned of a different electricity; and partly by the fpon-
taneous feparation and precipitation of that moisture, which
is known to be contained in confiderable quantities in the
air at all times, and the appearance of which, dripping down
the walls of our houses, &c. is one of the popular figns
Dr. Dobfon flates the annual evaporation at Liverpool,
taking the medium of four years, at 36,78 inches. Dr.
Halley laxes the annual evaporation of London at 48
inches. See Phil. Tranf. vol. lxi. part i. p. 262.

3. The effet of the wind is very confiderable, on a
double account; for the fame obervations weved a very odd
quality in the vapours of water, viz. that of adhering and
hanging to the furface that exhaled them, which they
clothe, as it were, with a fleece of vaporous air; which
once infefling the vapour, it thenceforward rises in lefs
quanity. Whence, the quantity of water left in twenty-
four hours, when the air was very fill from wind,
was very small, in proportion to what went away when
there was a strong gale of wind abroad to difipate the
fleece, and make room for the effillation of vapour; and
this, even though the experiment was made in a place as
clofe from the wind as could be contrived.

Add, that this fleece of water hanging on the furface
of waters in fill weather, is the occasion of very ftrange ap-
pearances, by the refraction of the vapour's differing from
and exceeding that of common air; whence every thing appears
railed,
VAR

raised, as houses like steeples, ships as on land above the water, the land raised, and as it were lifted, from the sea, &c.
4. The fame experiments shew, that the evaporation in May, June, July, and August, which are nearly equal, are about three times as great as those in the months of November, December, January, and February. Phil. Tranf. No. 212. or Abr. vol. ii. p. 110, &c.

Dr. Brownrigg, in his "Art of making Common Salt," p. 189, fixes the evaporation of some parts of England at 73.8 inches during the months of May, June, July, and August; and the evaporation of the whole year at more than 140 inches. The evaporation of the four summer months at Liverpool, on a medium of four years, was found to be only 18.88 inches. Dr. Hales calculates the greatest annual evaporation from the surface of the earth in England at 6.66 inches; and therefore the annual evaporation from a surface of water, is to the annual evaporation from the surface of the earth in Liverpool, as 36 to 6, or as 6 to 1. Phil. Tranf. vol. lxvii. ubi supra.

VAPOURS. Firey, Calidus Ignis, a term used by fome to express those exhalations from the earth, which either take fire of themselves on their bursting forth into the air, or are readily inflammable on the bringing of a candle to them. See DAMP, Gas, HYDROGEN, METEOR, and VENTILATION.

Many of the vapored burning lakes, affect the vaporizing the fumes burfting up through the water, and not to any quality of the water iflelf. Our famous burning-well at Wigan, in Lancashire, is of this kind. The common people affirm, that the water of this spring burns like oil; but there is nothing of truth in this. There burfts up a vapour through the earth in this place, which keeps the water bubbling, as if boiling over in the fire, though it is not warm; and the stream of this breath may be felt ifufing up in these places like a strong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with considerable violence for some time. There are coal-pits in the neighbourhood, and the air is certainly of the fame kind with that inflammable vapour often met with in those places, and which maybe prepared from iron diffolved in a proper meneunum. The water iflef, taken from the place, does not burn; and if the bottom be made dry, the vapour which ascends from it will burn as strongly as if the water were there. The flame is not difcoloured like that of fulphurous bodies, nor has it any bad fcent; and the fumes, as they are felt burfting out of the earth, by the hand held over the place, are hot. Phil. Tranf. No. 20.

VAPOUR-Bath. See VAPORISIUM, and BATH.

VAPOURS, in Medicins, a diacife popularly called the hypo, or the hypochondriac difeafe; and in men particularly the spleen. See HYPOCHONDRIANS.

Vapours supputed to be emitted from the womb, in women, we what otherwise call hysterical affections, or affections, or fits of the mother. See HYSTERIA.

VAPPA, a word used by the ancients to express dead wine, or wine deprived of all its fpirituous part.

The word is also metaphorically applied to a peculiar state of the blood, when it is in a low, disfpirited condition, as is the cafe even in healthy persons, when worn out with exceflive labour, and in cachectic and tertianous feverities.

VAR, in Geography, one of the twelve departments of the S.E. region of France, formerly Lower Provence, a maritime territory in N. lat. 43° 30', bounded on the N. by the department of the Lower Alps, on the E. by the county of Nice, on the S. and S.E. by the Mediterranean, and on the W. by the department of the Moutiers of the Rhone. Its territorial extent in kilometres is 7510, and in square
able share in founding the Russian state, and who were a northern tribe of Gothic descent and of warlike disposition and character. Their original country was probably Scandinavia; and they consisted of a combined multitude of Danes, Swedes, and Norwegians, who, perpetually in quest of adventures, established governments in the western and eastern parts of Europe, and produced revolutions, especially in the south, the consequences of which extended through one quarter of the globe. The first trace of their maritime expeditions is discoverable about the year 516; though it is thought probable that they carried on their piracies at an earlier period, and were generally comprehended under the name of Franks, who already appeared under the emperor Probus as enterprising mariners. In the year 795, they were first perceived in Ireland. About the year 813, they began their incursions by the Elbe into Friesland and Flanders; in process of time they advanced to Aquitain and along the Seine: about the year 840, they ravaged France; and in 857, made the conquest of Luna, and afterwards of Pisa, in Italy. In the year 862, Rurik founded the Russian monarchy, and became the father of a dynasty which reigned above 700 years. Accordingly, in the ninth century the Varangians conquered from the Russians, a kindred north-Scandinavian people, the earliest mention of whose name is in the year 839, before Rurik's reception in Novgorod, the modern districts of Reval, St. Petersburg, and Archangel; and subjected the Sclavonians, Krivitches, Tschudites, Velsenians, and Marzens, to a tribute. The Russians retired to Finland and Karelia; but the Sclavonians, in conjunction with the rest of the forenamed nations, drove out the Varangians, and formed themselves at the lake Ilmen, near Novgorod, into a federative democratical republic. Although the Varangians composed the predominant, and under Rurik the most consequential part of the people, yet Sclavonians and Russians were soon blended into one nation. As piracy was the exercise, the trade, the glory, and the virtue of the Scandinavian youth, the Baltic was the first scene of the naval achievements of the northern adventurers; they then visited the coasts of the Baltic, the select residence of Finnic and Sclavonian tribes; and the primitive Russians of the lake Ladoga paid a tribute, the skins of white squirrels, to these strangers, whom they saluted with the title of Varangians, or corsairs. Their superiority in arms, discipline, and honour, commanded the fear and veneration of the natives. In their wars against the more inland savages, the Varangians condescended to serve as friends and auxiliaries, and gradually, by choice or conquest, obtained the dominion of a people, whom they were qualified to protect. At length Rurik appeared; his influence was extended by his brothers; the example of service and usurcation was imitated by his companions in the southern provinces of Russia; and their establishments, by the usual methods of war and annexation, were cemented into the fabric of a powerful monarchy.

As long as the descendants of Rurik were considered as aliens and conquerors, they ruled by the sword of the Varangians, distributed estates and subjects to their faithful captains, and furnished their comforts with the produce of adventures from the Baltic coast. But when the Scandinavian chiefs had trucked a deep and permanent root into the foil, they mingled with the Russians in blood, religion, and language, and the first Waladimir had the merit of delivering his country from these foreign mercenaries. They had seated him on the throne; his riches were insufficient to satisfy their demands; but they listened to his pleasing advice, that they should seek, not a more grateful, but a more wealthy master; that they should embark for Greece, where, instead of the skins of squirrels, silk and gold would be the recompence of their service. At the same time the Russian prince admonished his Byzantine ally to disperse and employ, to recompense and refrain, these impetuous children of the north. Contemporary writers have recorded the introduction, name, and character, of the Varangians: each day they rose in confidence and esteem; the whole body was assembled at Constantinople to perform the duty of guards; and their strength was recruited by a numerous band of their countrymen from the island of Thule. On this occasion, the vague appellation of Thule is applied to England; and the new Varangians were a colony of English and Danes who fled from the yoke of the Norman conqueror. The habits of pilgrimage and piracy had approximated the countries of the earth; these exiles were entertained in the Byzantine court; and they preserved, till the last age of the empire, the inheritance of national loyalty, and the use of the Danish or English tongue. With their broad and double-edged battle-axes on their shoulders, they attended the Greek emperor to the temple, the senate, and the hippodrome; he feft and feated under their truly guard; and the keys of the palace, the treasury, and the capital, were held by the firm and faithful hands of the Varangians.

About the time of Rurik, a Norman of a similar name, Urlich, became famous in the history of Holland. Soon after this, Ofkold and Dir founded another sovereignty at Kief. In the tenth century Ragnvald reigned in Polotsk, from whose daughter, Rogned, the Russian annals derive the grand-dukes of Lithuania. About the year 1000, they took Apulia from the Greeks, and Sicily from the Arabians. They gave Normandy its name, after Rollo had wrested that country from the kings of France. Even the conquest of England by the Danes, in some degree formed a part of the history of these northern adventurers. Tooke's Ruff. vol. i. Gibbon's Rom. Emp. vol. x. See Sclavonians.

VARAHA, in Hindoo Mythology, a name of the god Vishnu, meaning a boar; he having in one of his ten grand incarnations assumed that form, called Varahavatara, which see.

VARAHAVATARA, is one of the ten grand incarnations of their god Vishnu. In this the god attuned, as is commonly said, the form of a boar, Varala; but is usually represented in pictures, with the head of that animal on the body of a man, four-armed, holding the attributes of Vishnu. On the elevated tusk of the boar rests a croucent, containing in its coacacy an epitome of the earth, which had been submerged in the ocean, as a punishment for its iniquities. So that this avatara, or incarnation, the third of Vishnu, seems to be a repetition of the story of the deluge, like the two former, which are named Matsyaavatara and Kurmaavatara, noticed under those articles. The second combines with it a portion of altronomical allegory, and none of the other ten avatatras have any apparent reference to the general catastrophe, so pointedly indicated by the third, which are underfoot to have occurred in the early ages of Hindoo history; if such a chaotic mafs as their fabulous records may be dignified by such a title.

There are many fables accounting for the shape assumed on this occasion by Vishnu, which our limits will not allow us to recite.

VARALLO, in Geography, a town of Italy, in the department of the Gogna, on the Seina; 24 miles N.W. of Novara. N. lat. 45° 59'. E. long. 8° 14'.

VARAMBON, or Varembon, a town of France, in the department of the Ain; 2 miles S.W. of Pont d'Ain.

VARAMUS,
VAR

VARAMUS, in Ancient Geography, a river of Italy, in Venetia, which discharges itself into the Anaflus. Pliny.

VARANASI, the classical name for the city of Benares, in the East Indies. (See BENARES.) This name is said to comprise that of two rivers which form a junction near the city.

VARANGI. See ACHALITHI.

VARANGUEBEC, in Geography, a town of France, in the department of the Channel; 10 miles W. of Carenton.

VARANIA, in Ancient Geography, a town of Servia, taken possession of in the year 1143 by Perigord, general of Manuel, emperor of Constaninople.

VARANO, in Geography, a lake of Naples, in Capitanata, which communicates with the Adriatic; 13 miles N.N.W. of Monte St. Angelo.

VARANO de Marches, a town of the duchy of Parma; 12 miles W.S.W. of Parma.

VARASDIN, a town of Croatia, on the S. side of the Drave, with a castle and citadel; near it is a warm bath; 186 miles N.W. of Belgrade. N. lat. 46º 30'. E. long. 16º 25'.

VARASELLYGUNGE, a town of Hindoostan, in Bahar; 14 miles S.S.E. of Bahar. N. lat. 25º 2'. E. long. 85º 56'.

VARBRESIE, a town of France, in the department of the Rhone and Loire; 9 miles N.W. of Lyons.

VARCES, a town of France, in the department of the Ière; 7 miles S. of Grenoble.

VARCHI, Benedetto, in Biography, was born at Florence in the year 1502, and destined to trade; but manifesting an inclination for literature, he was sent to the university of Padua. His progress in the belles lettres induced his father to educate him for the law at Pisa. But Benedetto, after the death of his father, devoted himself entirely to literature; and when the Strozzi, to whom he was attached, were obliged to quit Florence, he followed them, in 1534, first to Venice and then to Bologna. At Bologna, and also in Padua, he spent some years in study, and in cultivating an intercourse with learned men. At Padua he became a member of the Academy degli Infammati, and read public lectures on morals, and several dissertations on the poems of Petrarch, Bembo, and others. Cofmo I., grand duke of Tuscany, apprized of his reputation, recalled him to Florence, and alligned to him the office of writing a history of the late revolution in that city, with a yearly stipend. Whilst he was thus employed, he was attacked in the night by several persons, who apprehended that his narrative would not be favourable to them, and inflicted on him many wounds. When he recovered, he declined, from motives of prudence or delicacy, to inform against the perpetrators, though he knew them. In the Florentine academy, of which he was one year confid, he delivered lectures. Cofmo recomposed his services with the provovlish of Monte Varchi, on which occasion he took holy orders; but before he could remove thither, he died of an apoplexy in 1565, at the age of sixty-three; and his cullogy was delivered, at his funeral, by Lionardo Salviati.

Varchi was a man of general literature. He wrote a Florentine history, comprising the period from 1527 to 1538, in which he was chargable with gross adulation to the house of Medici. He also published several harangues, academical and funeral; poetical pieces, and a comedy in Italian. As a grammarian, he gained reputation by his dialogue "Ercolano," treating particularly of the Tuscan language. His translations of "Seneca on Benefits," and of the "Philosophical Confutation of Boethius," into Italian, are deemed elegant. His "Lezioni lette nel Accademia Fiorentina" comprehends much various erudition. Upon the whole, Varchi ranked as a man of learning, to whom Italian literature was much indebted. Moreri. Tirafochii.

VARCIA, in Ancient Geography, a town of Belgium Gaul, upon the route from Cambrai to Andematamun, between Vefontio and Andematamun, according to Antonine's Itinerary.

VARDANUS, COUBAN, a large river which discharges itself into the Euxine sea, and into the Palus Mazoises.

VARDAR, in Geography, a river of European Turkey, which rises near Kolumbatz, in Macedonia, and runs into the gulf of Saloniki; 16 miles W.S.W. of Saloniki.

VARDEGUS, a small island of Raffia, in the Frozen ocean; 100 miles N.N.W. of Kola. N. lat. 70º 25'. E. long. 30º 34'.

VARDEN, or WARDAN, or OWARDAN, a town of Egypt, on the W. branch of the Nile, anciently called Latopolis. In modern times it has been famous or rather infamous for the abode of pirates, who robbed the vessels which navigated the Nile. These robbers were routed out, and dispersed by Ali Bey. Here Father Siscard burned heaps of ancient manuscripts, deposited in a dove-house, as books of magic; 18 miles N.N.W. of Cairo.

VARDHUYUS. See WARDHUYUS.

VARDLE, in Rural Economy, a term applied in some cases to the eye or thimble of a gate, which has a spike only. See GATE.

VARDON, in Geography, a town of Abascia, on the Black sea; 28 miles W.N.W. of Mamak.

VARDONES, in Ancient Geography, a people of Germany, who formed a branch of the Vandals.

VARDULI, a people of Hispania Citerior, upon the coast, between the Pyrrenees to the E. and the Caritites to the W. Ptolemy has alligned to them the town of Menofca.

VARECA, in Botany, a bad and merely temporary name, taken from "Wetzuwerika," by which this fruit appears to be known in Ceylon. Gartner received it, with that appellation, from the collection of seeds at the Leyden garden, and thought it might confluxte a new genus. We shall give his description.—Garten. v. 1. 393. t. 62.—Clafs and order, as well as the Nat. Ord., unknown.

Gen. Ch. Flower unknown. Peric. Berry superior, of one cell, half an inch long, ovate, with fix angles, tipped with a short point; supported at the base by a small round disk, having fix flesh notches. Coat coriaceous, thin. Pulp by age become spongy and membranous, divided into partial cells for the reception of the seeds. Recepts three prominent ribs, attached to the inner coat of the berry, into which the external seeds are inserted. Seeds numerous, rather large, nearly ovate, rendered variously angular by mutual preffure, their colour a dampy brown, all inclosed in separate partial cells; the outer seeds attached to the coat of the fruit; the inner imbedded in its pulp. Integument double; the outer thick, coriaceous; inner membranous, very thin. Albumen the shape of the seed, thick, white, of the substance of an almond. Embryo nearly the limb of the albumen, compressed, pulp yellow. Carydides ovate, or rounded, leafy, flat, very thin. Redicile long, nearly cylin- drical, centrifugal, or indeterminate.

Eff. Ch. Flower... Berry superior, of one cell; pulp in many partial cells, appropriated to each seed. Seeds inserted into the coat of the berry.

Gartner observes, that the structure of this fruit agrees, in many points, with that of the Gourd tribe. Gourdaure; but it differs from all hitherto known of that tribe, in being
superior, and in having remarkably albuminous seeds, whereas the *Cucurbita* usually have no albumen. We would remark, with due deference to this justly celebrated carpologic, that the partial cells of the pulp appear to be merely what must occur, in the drying up of any such berry, and probably have no existence in a recent state of the fruit. They are therefore scarcely entitled to be mentioned in the essential character.

VARIELLES SOMMERES, in Geography, a town of France, in the department of the Vienne; 7 miles N.E. of Civray.

VARIEL, a town of Germany, in the county of Oldenburg; 22 miles N. of Oldenburg.

VARELLE, a small island in the Chinese sea, near the E. coast of Malacca. N. lat. 3° 18'. E. long. 104°.

VAREN, a town of France, in the department of the Aveyron; 18 miles N.W. of Alby.

VARENA, a town of Italy, on the lake of Como; 15 miles N.E. of Como.

VARENTAUX, a town of Canada, on the right bank of the St. Lawrence. N. lat. 43° 41'. W. long. 73° 10'.—Allo, a town of France, in the department of the Allier; 18 miles N. of Cuffet.—Allo, a town of South Carolina; 20 miles E. of Queenborough.

VARENE la Grande, a town of France, in the department of the Saône et Loire; 6 miles S. of Chalon.

VARENNES, a town of France, and seat of a tribunal, in the department of the Meuse. In this town the king and queen of France, with the dauphin, the princes royal, and the princes Elizabeth, were stopped in their journey to Montmedy, when they attempted to escape, in the month of June 1791; 7 miles N. of Clermont en Argonne. N. lat. 49° 14'. E. long. 5° 7'.—Allo, a town of France, in the department of the Upper Marne; 6 miles S.W. of Bourgogne.

VARENTANUM, VARENTUM, in Ancient Geography, a town of Italy, in Etruria, according to the Itinerary of Antonine.

VARESA, in Geography, a town of Genoa; 10 miles N.W. of Brugnato.

VARESIO, a town of Italy, capital of the department of the Venetia; 24 miles N.N.W. of Milan. N. lat. 45° 6'. E. long. 8° 49'.

VARGAS, Luis de, in Biography, a Spanish painter of celebrity, was born at Seville in 1528. He went to Italy to improve his talents, and passed seven years in Rome, where he principally directed his attention to Rafaele and P. Perugino's works. When he returned to Seville, he found a formidable rival in Pedro Campana, and he therefore returned to Italy to cultivate his powers still farther; and on returning a second time to his native city, obtained reputation, and employment. He painted for the cathedral two pictures, viz. Christ bearing his Cross, and Adam and Eve; the latter of which is regarded as his master-piece. He executed several other works for the churches in Seville, both in oil and fresco; and he was no less distinguished for his skill in portraiture, particularly in his portrait of Donna Juana Cortes, duchess of Alcalá. He died at Seville in 1550, aged 62.

VARGAS MEXIA, FRANCISCO de, a Spanish lawyer, who occupied several posts in the judicature under Charles V., and became advocate-fiscal in the supreme council of Castile, was beat by Charles, in 1548, to Bologna, to protect against the translation of the council of Trent to that city. After the dissolution of this council, he spent seven or eight years in a public capacity at Venice. Being ordered by Philip II. to act as resident deputy to the Spanish am-bassador at Rome, his known learning and integrity caused him to be much consulted by the cardinals on the subject of episcopal jurisdiction. On his return to Spain, he was nominated a counselor of state; but at length retired from the world to the monastery of Cifías near Toledo. He was author of several works; particularly "De Episcoporum Jurisdictione, et Pontificis Maximis Authoritate," Venet. 4to. 1563; "Commentaries upon War again the Infidels," &c. &c. In 1700, Le Vaissot published in French, at Amsterdam, "Letters and Memoirs of Vargass," relative to the council of Trent, which are said not to be very respectful to that assembly. Moreni.

VARGAS, in Geography, a town of Spain, in the province of Bihac; 11 miles S.S.W. of Santander.

VARGEL, or VARGULA, an ancient town of Germany, in the territory of Erfurt; 10 miles N.W. of Erfurt.

VARGO, a town of Spain, in Catalonia; 14 miles N. of Solfoña.

VAREHEL, a town of Transylvania, built on the ruins of Sârmizagetha, the ancient capital of Dacia, afterwards named by Trajan, Ulpia Traiana; 60 miles E. of Teils; 25 miles S. of Sârbaleu.

VARI. Persons were formerly so termed, when their legs were deformed, and their toes turned in an unusual degree inwards.

VARI, in Medicine, hard, inflamed tubercles, occurring on the face and neck of young people, of both sexes, after the commencement of the period of puberty.

This eruption, which disfigures the countenance at that period of life when personal appearance is usually of the greatest importance in the estimation of the persons affected, has been therefore the object of medical attention from the earliest ages, though in itself but a trivial complaint. Celsius observes, that the Roman ladies in his time were so solicitous of maintaining their beauty, that he deemed it necessary to mention the remedies for this affection of the skin, which otherwise he considered as too trifling for the notice of the physician. "Pene inopinata fent curare varis et lentueilas et pholéides (freckles and sun-spots); fed eripi tamen fenuinis cura cultus fui non poterit." (De Mediciniæ, lib. vi. cap. 5.) The circumstance of this eruption occurring at the period of puberty, and being brought to light by the children, and to their complaint, was given it by the Greek physicians, namely, *iambos* and *acne*. The term *iambos* signifying the langa, or first down of the beard, during which it begins; and *acne*, or *acnes*, implying that it appears at the *acnes*, or period of full growth and evolution of the body. (See Julius Pollux, Onomatolicon, lib. iv. cap. 25. Aetius, Tetrabible ii. ferm. iv. cap. 15, &c.) Under this term *acne*, Dr. Willan arranged the diseased in the order of tubercles, and described four varieties of the eruption, with the epithets *simplus*, *punuitata*, *indurata*, and *rofacs*. See Dr. Bateman's Practical Synopsis of Cutaneous Disoeaes, according to the Classification of Dr. Willan, p. 275.

The *acne*, then, consists of an eruption of these *varis*, or difficult, hard, inflamed tubercles, which are sometimes permanent for a considerable length of time, and sometimes suppurate very slowly and partially, forming only a little matter at the top. They usually appear on the face, especially on the forehead, temples, and chin, and not infrequently on the neck, shoulders, and upper part of the breast, to the extent that might be covered by a tippet; but never defecting to the lower parts of the trunk, or appearing on the extremities. This, however, does not depend on the parts being uncovered; for the limitation is the same in both sexes. As the progress of each tubercle is slow, and they appear in succession, they are generally seen at the same time in their various stages of growth and decline; and, in the
the more violent cases, are intermixed also with the marks or vestiges of those which have subsided.

In different cases, the progress and appearance of the eruption vary considerably, which has given rise to the subdivision of species suggested by Dr. Willan. Thus in the acne simplex, the eruption consists of small vari, which appear singly, and are not very numerous, nor accompanied by much inflammation, nor by any intermediate affection of the skin. Many of the tubercles do not proceed to suppuration; but gradually rise, become moderately inflamed, and again flowly subside, in the course of eight or ten days, leaving a transient purplish-red mark behind. But others go on to a partial suppuration, the whole process of which occupies from a fortnight to three weeks. The tubercles are felt as a small hard nodule in the skin of the size of a pin's head, and enlarge for three or four days, when they begin to inflame: about the sixth or seventh day they attain their greatest magnitude, are prominent, red, smooth, and shining, and hard and painful to the touch. After two or three days more, a small speck of yellow matter appears on the apices of some of the tubercles; and when these afterwards break, a thinner humour is secreted, which soon dries into a yellowish scab. The inflammation now gradually declines, the size and hardness of the tubercles diminish, and the small scab becomes loofened at the edges, and at length falls off at about the end of the third week. The individual tubercles, which rise and suppurate in succession, pass through a similar course.

In the acne indurata, the tubercles are larger, as well as more indurated and permanent, than in the former variety. They rise often in considerable numbers, of a conical, or oblong conoidal form, and are occasionally somewhat acuminate: as it tending to immediate suppuration, being at the same time of a bright-roseate hue; yet many of them continue in a hard and elevated state for a great length of time, without any disposition to suppurate. Others, however, pass on very slowly to suppuration, the matter not being completely formed in them for several weeks, and then only a small part of the tubercles are removed by that process. Sometimes two or three coalesce, forming a large irregular tubercle, which occasionally suppurates at the separate apices, and sometimes only at the largest. In whatever mode they proceed, the vivid hue of the tubercles gradually becomes more purple or even livid, especially in those which show no tendency to suppuration. Slight crusts form upon the suppurating tubercles, which after some time fall off, leaving small scars, surrounded by hard tubours of the same dark red colour; and these sometimes suppurate again at uncertain periods, and sometimes flowly subside and disappear, leaving a pale, or livid discolouration, and occasionally a slight depression, which is long in wearing off.

The tubercles, even when they do not suppurate, but espe-
cially while they continue highly red, are always sore and tender to the touch; so that wailing, shaking, the friction of the clothes, &c. are somewhat painful. In its mildest severe form, this eruption nearly covers the face, breast, shoulders, and top of the back, but does not descend lower than an ordinary tippet in women: yet this limitation of the dis-
order is independent of the exposure of those parts; for it occurs equally in men and women. In a few instances in young men, an extensive eruption of acne indurata has been seen affecting these covered parts, while the face remained nearly free from it. By the successive rise and progress of the tumours, the whole surface, within the limits just men-
tioned, was spotted with the red and livid tubercles, inter-
mixed with the purple discolourations and depressions left by those which had subsided, and variegated with yellow sup-

purating points and small crusts, so that very little of the natural skin appeared. Sometimes the black puncta of the sebaceous ducts were likewise mixed with the vari and their sequelae.

Cure of Vari.—Vari being generally a local disease, the acne is to be treated chiefly by external applications. Except in females, indeed, this variety of the eruption seldom calls for the attention of medical men. The ancients agree in recommending a number of stimulant applications, with the view of discussing the "thick humours," which were supposed to constitute the vari. Lotions and liniments, containing vinegar and honey, sometimes combined with an emulsion of bitter almonds, and sometimes with turpentine, resin, myrrh, and other gums, or with alum, icap, and Cinamomum bark, or the bruised roots of the lily, cyclamen, narcissus, &c. were the substances which they principally employed. They were doublets corrected as to the principle, as a gentle stimulus to the skin is the most safe and effectual remedy. The apprehensions, which have been strongly ex-
pressed by the humoral pathologists, of producing internal disorder by the sudden repulsion, as it has been called, of these cutaneous eruptions, are not altogether hypothetical. Head-ache, and affections of the stomach, and bowels, have sometimes been thus produced, which have ceased on the reappearance of the eruption; but, on the whole, as far as our observance goes, this alternation of disease is less frequent and obvious in this form of acne, than in the pustular and crustose eruptions of the face and head.

The stimulant applications, which are most easily prepar-
tioned to the irritability of the tubercles, are lotions containing alcohol, which may be reduced or strengthened according to circumstances, by the addition of any distilled water. It is not easy to describe the appearances of the eruption, which indicate any certain degree of strength in the lotion; but a little observation will teach this discrimination.

If the tubercles are considerably inflamed, and a great number of them pustular, a dilute mixture will be re-
quiate; containing, for example, equal parts of spiritus tenius and of rofe or elder-flowet water. The effect of a very acid lotion, under such circumstances, is to multiply the pustules, to render many of them confluent, and to pro-
duce the formation of a crust of some extent, as well as to excite an inflammatory redness in the adjoining skin. A fluid increase of the inflammation, indeed, is sometimes oc-
casioned by the first applications of a weak stimulus; but this is of short duration, and the skin soon bears an aug-
mentation of the stimulant until at length the pure spirit is borne with advantage, as the inflammatory disposition subsides. Under the latter circumstances, even a consider-
able additional stimulus is often useful; such as from half a grain to a grain or more of the muricate of mercury, in each ounce of the spirit; or a drop or more of the liquor ja-
tafic, or of the muricate acid, in six ounces. Acetic acid, as recommended by the ancients, and the liquor com-
mon acetas, afford also an agreeable stimulant, in proper proportions. Sulphur yields a small portion of its substance to boiling water, poured upon it, and allowed to infuse for twelve or fourteen hours; a quart of water being added to about an ounce of broken sulphur. A lotion of this nature has been found advantageous in slight cases of acne simplex, and especially in removing the roughnesses and dimples of the face connected with it.

Connected with the eruption of vari, and often giving rise to them, is that appearance of black points on the face and neck, surrounded by a raised border of cuticle, to which the appellation of acne punctata was given.
by Dr. Willan. These are vulgarly considered as the extremities of small worms or grubs, because, when they are pellucid, a sort of worm-like appendage is found attached to them; but they are, in fact, only little plugs of concreted mucus or phlegmaceous matter, moulded in the small ducts of the cuticular glands into this vernacular form, the extremity of which is blackened by contact with the air. In consequence of this dilatation of their ducts, the glands themselves sometimes inflame, and form small tubercles, or varii, with the little black points upon their surface, which partially suppurate, as in the preceding species; but many of them remain stationary for a long period, without ever passing into the inflammatory state. Not unfrequently they are intermixed with a few varii, in which the puncta have not appeared.

The preceding varieties of the eruption of varii occur only in young persons, of either sex, from the period of puberty to the age of thirty or thirty-five, and principally in those of the faguide temperaments, and they are generally accompanied by good health, and are totally unconnected with any disorder, or with habits of intemperance; but there is another variety of this eruption, which does not occur till after the age of forty, which is always, except from strong hereditary tint, sympathetic of some diseaue of the digestive organs, or vifcera connected with them, and which therefore is not so easily cured, and is not even benefited by the fame local means which are so efficacious in the former species. This variety of the diseaue is the gutta rofea of medical authors, and the acme rofeae of Dr. Willan.

This eruption of varri, indeed, differs in its appearance very essentially from the preceding species. In addition to the eruption of small suppurating tubercles, there is also a shining redness, and an irregular granulated appearance of the skin of that part of the face which is affected, which is not the part usually occupied by the former species. The redness commonly appears first at the end of the nose, and afterwards spreads from both sides of the nose to the cheeks; the whole of which, however, it very seldom covers. In the commencement the redness is not uniformly vivid, but is paler in the morning, and readily increased to an intense scarlet after dinner, or at any time if a glass of wine or spirits be taken; or if the patient be heated by exercise, or by sitting near a fire. After some continuance in this state, the texture of the cuticle becomes gradually thickened, and its surface uneven or granulated, and variegated by reticulations of enlarged cutaneous veins, with smaller red lines stretching across the cheeks, and sometimes by the intermixture of small suppurating varri, which successively arise on different parts of the face. Where there is a strong hereditary predisposition, or by the constant immoderate use of wine and spirituous liquors, this diseaue may affect the greater part of the face, even the forehead and skin; but the nose especially, in such cases, becomes tumid, and of a fiery red colour: and, in advanced life, it sometimes enlarges to an immoderate size, the noftrils being dilated and patulous, or the ade slurred, as it were, and divided into separate lobes.

Little can be done in way of cure for this species of varri, the visceral or constitutional malady being the root of the disease; against which, of course, the remedies, both moral and physical, must be directed.

Varri, in Zoology, a name given to the maueuco, or lemur catiis of Linnaeus, with his tail marked with rings of black and white; it is about the size of a cat, and inhabits Madagascar and the neighbouring isles. The varri of Buffon is the ruffled maueuco of Pennant, the black maueuco of Edwards, and lemur candatus nigri, collaris barbato, of Linneus. It has orange-coloured irides; long hair round the sides of the head, standing out like a ruff; long tail; the colour wholly black, but sometimes white spotted with black; the feet black. It inhabits Madagascar; is very fierce in a wild state; and makes so violent a noise in the woods, that the noise of two may be eafily mistaken for that of a hundred; when tamed, gentle and good-natured. Pennant.

Varri, in Geography, a town of Hindoflan, in Concan; 25 miles N. of Goa.

VARIA, in Ancient Geography, a town of Hispania Citerior, on the Iberus, N.W. of Calagarius.

VARIA, Vico-Vario, a town of Italy, in the Sabine territory, but belonging to the Latins; situated on the Valerian way; 8 miles from Tibur, and 27 from Rome. It was also called Valeria.

Varia, in Zoology, a name by which some authors have called the leopard, or pardalis, from the beautiful variegations with which it is marked.

VARIABLE, in Geometry and Analytics, is a term applied by mathematicians to such quantities as either increase or diminish, according as some other quantity either increases or diminishes.

Thus, the semiordinates and absefles of an elliptis, &c. are variable quantities; because, if the one increase, the others increase likewise.

They are thus called, in contradifition to conflant, or given, or flable quantities; which are always the fame, though others change: as the semidiameter of a circle, which remains the fame, though the absefles and semiordinates increase.

Variable quantities are usually denoted by the laft letters of the alphabet, x, y. z.

Some authors, instead of variable and conflant quantities, use the terms fluent and flable quantities.

The infinitely small quantity by which a variable quantity is continually increasing or diminishing, is called the increment or decrement, or difference; and the velocity with which it increases or decreases at any given point, is called its fluxion; the calculation of which is the Subject of the new methodus differentialis, or doctrine of fluxions.

VARIABLE Wind. See Wind.

VARIAM, in Geography, a town of Perfa, in the province of Irak; 120 miles E. of Hamadan.

VARIANA, in Ancient Geography, a town of Lower Media, upon the route from Viminacium to Nisioedia, between Augufót and Valeriana. Anton. Itin.

VARIANÆ, a town of Pannonia, upon the route from Emona to Sirmium, between Sificia and Meneiane. Anton. Itin.

VARIANCE, Variantia, in Law, an alteration or change of condition in a person, or thing, after some former concern or tranfation therewith.
Thus, if the commonality of a town make a composition with a lord, and afterwards bailiffs be granted by the king to the same town, there, if the lord commence any suit for breach of the composition, he must vary from the word commonality, used in the composition, and use bailiffs and commonly. 

VARIANCE is also used for an alteration of something formerly laid in a plea: or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded.

VARIATION of Quantities, in Algebra. See Changes and Combination.

VARIATION, in Astronomy. The variation of the moon, called by Bullialdus the reflection of her light, is the third inequality observed in the moon's motion; by which, when out of the quadratures, her true place differs from her place twice equated. See Place, Equation, &c.

Sir Isaac Newton takes the moon's variation to arise partly from the form of her orbit, which is an ellipsis; and partly from the inequality of the parts of space, which the moon describes in equal times, by a radius drawn to the earth.

To find the greatest variation, observe the moon's longitude in the octants; and, for the time of observation, compute the moon's place twice equated: the difference between the computed and the observed place is the greatest variation. Tycho makes the greatest variation 4° 30'; Kepler makes it 5°49'; Sir Isaac Newton makes the greatest variation, at a mean distance, between the sun and the earth, to be 35°16': at the other distances, the greatest variation is in a ratio compounded of the duplicate ratio of the time of the moon's synodical revolution directly, and the triplicate ratio of the distance of the sun from the earth inversely. And, therefore, in the sun's apogee, the greatest variation is 33°14', and in his perigee, 37°11'; provided that the excentricity of the sun be to the tranverse semidiameter of the orbit magnus, as 164 to 1000. Or, taking the mean motions of the moon from the sun, as they are stated in Dr. Halley's tables, and the greatest variation at the mean distance of the earth from the sun will be 35° 7', in the apogee of the sun 33° 27', and in his perigee 36° 51'. Phil. Nat. Prine. Math. prop. 29. lib. iii. apud Horsley's Newtoni Opera, vol. iii. pars. 4th ed.

VARIATION, in Geography, Navigation, &c. a term applied to the deviation of the magnetic needle, or compass, from the true north point, towards either east or west; called also the declination. The variation, or declination, of the needle, is properly defined, the angle which a magnetic needle, suspended at liberty, makes with the meridian line on a horizontal plane; or an arc of the horizon, comprehended between the true and the magnetic meridian.

In sea-language, the variation is usually called north-easting, or north-westing.

All magnetic bodies, we find, range themselves, in some degree, to the meridian; but it is rare that they fall in precisely with it: in one place they decline from the north to the east, and from the south to the west; and in another place, on the contrary, from the north to the west, and from the south to the east; and that too differently at different times.

The variation of the compass could not be long a feaver, after the invention of the compass itself: according to Ferdinand, the son of Columbus, in his life written in Spanish, and printed in Italian at Venice in 1571, affirms, that his father observed it on the 14th of September, 1492: though others seem to attribute the discovery of it to Sebastian Cabot, a Venetian, employed in the service of our king Henry VII. about the year 1500. And as this variation differs in different places, Gonzales d'Ovieda found there was none at the Azores; whence some geographers have thought fit in their maps to make their first meridian pass through one of these islands; it not being then known that the variation altered in time. See Gilbert de Magnete, Lond. 1600, p. 47; or Purchas's Pilgrims, Lond. 1625, book iii. fecl. 1. See Variation of the Magnet.

Various are the hypotheses framed to account for this extraordinary phenomenon; of which we shall mention some of the later, and more probable, only premising, that Mr. Robert Norman, the inventor of the dipping-needle (which fee), disputes against Cortés's notion, that the variation was caused by a point in the heavens, contending that it should be sought for in the earth, and proposes how to discover its place.

The first is that of Gilbert (De Magnete, lib. iv. p. 151, &c.) which is followed by Cabeus, &c.

This notion is, that it is the earth, or land, that draws the needle out of its meridian direction; and hence they argue, that the needle varied more or less, as it was more or less distant from any great continent; consequently, that if it were placed in the middle of an ocean, equally distant from equal tracks of land on each side, eastward and westward, it would not decline either to the one or the other, but point southly north and south. Thus they say, in the Azores islands, which are equally distant from Africa on the east, and America on the west, there is, in effect, found no variation: but as from the Azores you sail towards Africa, the needle begins to decline from the north to the east; and that still more and more, till you reach the shore.

If you still proceed eastward, the declination gradually diminishes again, by reason of the land left behind on the west, which continues to draw the needle.

The same holds till you arrive at a place where there are equal tracks of lands on each side; and there again there is no variation.

The observations of our navigators, in their first East India voyages, seemed to confirm this fable; as they proceeded towards the Cape of Good Hope the variation is still eastward; at length arriving at the Cape De las Aguillias, p. d. of the Needles, the meridian line, then dividing Africa into two equal parts, there is no variation at all; but as they proceeded farther, and leave the African coast on the west, the variation becomes westward.

But the misfortune is, the law does not hold universally; in effect, a great number of observations of the variations, in various parts, made and collected by Dr. Halley, overturn the whole theory.

Some, therefore, have recourse to the frame and compasses of the earth, considet-red as interwoven with rocks and strata, which being generally found to run towards the poles, the needle has been observed to have a general tendency that way; but which seldom going perfectly in the direction of the meridian, the needle, by consequence, has commonly a variation.

Others hold various parts of the earth to have various degrees of the magnetic virtue, as some are more intermixed with heterogeneous matters, which prevent the true action or effect of it, than others.

Others ascribe all to magnetic rocks and iron mines, which, affording more of the magnetic matter than other parts, draw the needle more.

Lastly, others imagine earthquakes, or high tides, to have disturbed and dislocated several considerable parts of the earth, and so changed the magnetic axis of the globe, which originally was the same with the axis of the globe itself.
VARIATION.

But still, that great phenomenon, the variation of the variation, i.e. the continual change of the declination in one and the same place, which the modern observations daily confirm, is not accountable for on any of these foundations, nor even is it consistent with them.

Dr. Hooke communicated to the Royal Society, in 1674, a theory of the subject, the substance of which is, that the magnet has its peculiar pole distant ten degrees from the pole of the earth, about which it moves, so as to make a revolution in 370 years; whereas the variation (he adds) has altered at about ten or ten minutes every year, and will probably continue to do so for some time, till it begins to become slower and slower, and will at length be stationary and retrograde, and in all probability may return. Birch's Hist. of the Royal Society, vol. iii. p. 131.

Dr. Halley, in the Philosophical Transactions, No. 148, invented a new theory, founded on a great number of observations, many of which were made expressly for the purpose by order of the government; but as they do not extend to a more recent date than about 1680, and as perpetual changes are going on in the variation of different places, the table of results of this learned philosopher is now of little use; we shall therefore, avail ourselves of the history of these changes, as published in a recent work on the variation of the compass by W. Bain, master in the royal navy; which contains much important information on this subject, and is deserving of the particular attention of every one engaged in the management and navigation of vessels.

At London, in 1580, the quantity of variation was found to be 11° 15' E.; in 1662, 6° E.; in 1634, 4° 5' E.; and in 1657, the needle coincided with the true poles of the world; so that a period of 87 years elapsed in changing the 11° 15' of easterly variation in that city to zero, or until the variation began to take a westerly direction. In 1672, the variation was 2° 30' W.; in 1725, 14° 1' W.; in 1747, 17° 40' W.; in 1780, 22° 41' W.; and in 1793, viz. 135 years after the time when the variation was zero, it was nearly 24° 35' W.; and it is still nearly the same.

At Paris, in 1550, the variation was 8° E.; and in 1660, the needle pointed to the true poles of the world; in 1681, the variation was 2° 2' W.; in 1706, 18° 20' W.; in 1804, 22° 20' W. Hence it follows, that whilst the variation was undergoing an annual change of 10° 4' during a period of 213 years in London, the yearly change at Paris during a term of 254 years was only 7° 10'.

At Dublin, in 1657, the needle coincided with the true poles of the world; and in 1791, the variation was 27° 23' W.; exceeding the variation observed at London by 3° or 4'; and, consequently, the annual change during 134 years, must have been about 12° 10'.

While the variation was undergoing this change at London, Paris, and Dublin; we find nearly a corresponding change at Cape Aguilhas, and at the Cape of Good Hope.

At the former of these places there was no variation in 1600, and in 1692, it amounted to 11° W. And at the Cape of Good Hope, in 1700, the variation was nearly 10° W.; and in 1791, it had increased to 24° 31' 52'' W.; so that during a period of 91 years, the annual change in the variation at this place, during a period of 194 years, has been at the rate of 7° 52'' E.

At Cape Comorin, in 1620, the variation was 14° 20' W.; in 1688, 7° 30'; in 1756, 0° 15' W.; and in 1816, there was still no variation at this place; therefore, during a period of 137 years, the mean annual change was 6° 17' W.; but this includes a term of 60 years, in which there appears to have been a very small change in the declination, viz. about 15'' annually.

The phenomena presented by the variation at Cape Horn and its vicinity, are extremely different from those observed at the Cape of Good Hope, Paris, and London.

In 1683, in S. lat. 57° 27', W. long. 57° 28', the variation was found to be 23° 10' E.; in 1775, in S. lat. 56° 27', W. long. 54°, the variation was 24° 23' E.; in 1876, in S. lat. 53° W. long. 50° 4; the variation was 22° 47' E. and in 1795, in S. lat. 57° W. long. 67°, the variation was exactly 23° E. Hence it follows, that during a period of 112 years, the variation near Cape Horn has neither increased nor diminished in a perceptible manner.

At Cambridge, in Massachusetts, in 1708, the variation was found to be 9° W.; and since that period, it has been diminishing at the rate of 1° 6' annually; whilst at Jamaica, Barbadoes, and Lima, the variation has undergone no change during a period of 140 years. In the northern hemisphere, in the parallel of Spitzbergen, Davis's Straits, Hudson's Bay, &c. the same quantity of variation appears to have existed during the space of 150 years. The quantity or variation from Cape Comorin eastward, towards Nicaragua islands, Java, Ceram, Anibouya, Timor, &c. is so very small, as to tend to induce navigators to advert to it in their calculations; and is subject to little or no change. It may, however, be worthy of remark, that 60 miles east from the coast of Coromandel, about the meridian of Madras, the variation changes from east to west; and the same local changes probably take place on the coasts of Chili, Peru, and Mexico. In 1724, from Valparayfo to Acapulco, a distance of 50° of latitude, the variation was very inconsiderable; for from the former of these places to Lima, it never exceeds 3° E.; and from Lima to the latter place, never more than 4° W.

The greatest variation that the author, from whom the preceding abstract has been made, is acquainted with, is that which has been observed between Cape Farewell and Labrador, in Hudson's Straits and Baffin's Bay. In N. lat. 52° W. long. 52°, it was found by the author above alluded to, to be 40° 10' 53'' W.; and as high as N. lat. 60°, in about the same longitude, it was found to be 50° or 52°; but he expresses some doubt whether this great excess of variation might not have been partially produced by the effects of local attraction.

In 1616, in N. lat. 78° W. long. 80° (Baffin's Bay), the variation was found to be 57° W.; and in 1757, N. lat. 62° W. long. 65°, the variation was 42° W.; and in the same year, in N. lat. 64°, W. long. 70°, the variation was 43° W.; and in all these high latitudes, the variation still continues nearly the same.

On the west side of America, in the same parallel of latitude as Davis's Straits, Cape Farewell, &c. we perceive the variation assuming another character, and seldom exceeding half the quantity found at the above-mentioned places.

In 1786, in N. lat. 53° W. long. 145° 21' from Paris, the variation was from 23° to 24° E.; and in the same year, in N. lat. 58° 35', W. long. 138°; it was 25° E.; and in Port des Francais, in N. lat. 56° 37', W. long. 147° 32'; the variation, as ascertained by the meridian line, amounted to 25° E.; in 1792, in N. lat. 52°, W. long. 129°; the variation was only 20° 41' E.; and in 1794, in N. lat. 61° 17', W. long. 149° 7', 20° 30' easterly variation was found the greatest quantity observed by Vancouver while on that coast.
VARIATION.

But of all the places on the globe with which we are acquainted, none exhibit such wonderful phenomena in the variation as the coasts of China, Corea, Tartary, Japan, and Kamtschatka northward.

In 1787, from Macao to N. lat. 41°. E. long. 136° from Paris, the quantity of westerly variation never exceeded 2°; and from this point to N. lat. 51°1/3°. E. long. 142°2/3°, where the variation was only 53° E., the quantity never exceeded 3°.

In 1804, in N. lat. 52°. E. long. 143° from Paris, there was no variation; 16° farther to the E., and 45° to the S., 5° 20' of westerly variation was observed; and in 1779, in N. lat. 69° 55'. E. long. 105° 14' (Bering's Straits), there was found 35° 37' w. variation.

From observations made between 1760 and 1779, there appeared three places or points on the globe where the change in the variation was much greater than elsewhere.

These were, first, in the middle of the Indian ocean, from 10° to 15° S. lat., and from 64° to 69° E. long., where the change was 11° and 11° 45'; secondly, in the Ethiopian sea, from 5° N., to 20° or 25° S. lat., and from 10° to 15° or 20° E. long., the change in the variation was about 10°; and thirdly, at 50° N. lat., and between 17° E. and 10° W. long., the change was nearly 11°. In these different places, the variation has since continued to increase at nearly the same rate.

During the same interval it was also ascertained, that there were four places or points on the globe where the variation has undergone no change.

These were, first, from the eastern point of Africa to the farthest of the Bermuda islands; secondly, the curious islands of the Medusa and part of Zanzibar; thirdly, that part of the ocean which is to the S. and E. of the Sunda islands, between them and New Holland; and fourthly, in the feral sea, about 4° S. lat., and 97° E. long., that is, in the middle of the fpace comprised between the western angle of New Holland and the southern point of Africa. In all these places, the variation did not vary perceptibly during 15 years. And it may be remarked, that observations made since the above period, have not shewn any change worthy of notice in its quantity at the above-mentioned places.

Some intelligent sea-officers are of opinion, that in the western part of the English Channel, the westerly variation has begun to decline, which others affirm, that the variation is still increasing in the Channel, and as far westward as W. long. 15°, in N. lat. 51°, at which place they say the variation amounts to 30° W. Neither of these opinions, however, can, according to Mr. Bain, be relied on as correct, though each may have been deduced from observation. If the head of the ship is on the right point of the compass at the time of observation, from 20° to 25° of variation will be observed; but on the other hand, if the ship's head is at the west, at the time of observation, the variation will amount to 30° or 33°.

The circumstance above alluded to, of the apparent variation being so much influenced by the local attraction of the ship, is certainly of the highest importance; and the means which Mr. Bain has adopted of making it generally known are highly laudable: at the same time, we cannot but feel considerable doubt, after this fact is once pointed out, of the accuracy of many of the observations stated in the preceding pages, as several of these were made by persons wholly unacquainted with such an influence, which seems to have been entirely unknown till Mr. Wales, the astronomer, who failed with Capt. Cook, first noticed the phenomenon; and his observations have been since confirmed by Capt. Flinders; and Mr. Bain, in the work we have above alluded to, has added many additional facts to those before known, and to which we shall have again occasion to refer; but in the first place, it will be proper to infer a general table of variations in different latitudes, as given in the Philosophical Transactions for 1757, with additional observations of the above authors.

It may not be amiss to add here, as belonging to the history of this subject, that we owe the first variation chart to Dr. Halley. Previously to this period he had collected, and made, a multitude of observations on the variation of the needle in many parts of the world, and was enabled to draw on a Mercator's chart, lines shewing the variation of the compass in the places through which they passed. But as the deviation of the magnetic meridian from the true one was then, as now, subject to continual alteration, this chart was soon found useless.

However, in 1744, Mountain and Dobson published a new variation chart, adapted to that year; which being well received, they published a second, adapted to 1756; and a third in the following year: the last we know of.

Nicholson strongly recommends the employment of the variation as a means of finding the longitude at sea; but navigators are long since convinced of its inadequacy. Vancouver, speaking of this subject, says, "This very able seaman, Nicholson, still wedded to formerly-adopted opinions, strongly recommends the variation of the compass as a means for ascertaining the longitude at sea; yet, had we been better provided, we might have searched for the Cape of Good Hope, agreeable to his propositions, to little effect; for when we were in lat. 35° 17' S., with 20° 16' W. variation, we had only reached the long. of 6° 30' W., and again, when in lat. 35° 22' S., with 22° 47' W. variation, we had only advanced to the long. of 11° 25', instead of being, according to Mr. Nicholson's hypothesis, in the first instance, nearly under the meridian of the Cape of Good Hope, and in the second, under that of Cape Agulhas; and it was not until we had nearly 26° W. variation, that we approached the meridian of the Cape of Good Hope. The observations for the variation were made with the greatest care and attention; and though generally considered as correct, they differed from one to three, and sometimes to four degrees; not only when made by different compasses, placed in different situations on board, and the ships on different tacks, but by the same compass in the same situation, and at moderate intervals of time; the difference in the results of such observations, at the same time, not preferring the least degree of uniformity. Hence the aberration amounts nearly to an absurdity, which fluctuates, at that with 20° to 20° 10', or 20° 30' westerly variation, you will be certain of such and such longitudes; and it is greatly to be feared, that navigators who rely on such means for ascertaining their situation in the ocean, will render themselves liable to errors that may be attended with the most fatal consequences."

A Table.
A Table exhibiting the Changes of Variation from the Year 1700, in the most frequented Seas.

VARIATION.

Of the Curves of no Variation.—In the preceding part of this article, we have principally alluded to the variation east or west, at different times and in different places; but it is no less interesting to trace the curve in which no variation is observed. We have seen, that there are certain points in the northern and southern hemispheres where the needle points to the true poles of the world; these points, however, are not all situated on the same meridian, but form an irregular curve, influenced different ways, and in perpetual motion.

In the northern hemisphere, a curve of no variation moved from west to east during two centuries prior to 1662. This curve first passed the Azores, then the meridian of London, and, after a certain number of years, the meridian of Paris. But in the southern hemisphere, there was another curve of no variation moving from east to west. This curve first passed Cape Aguilhas, and then the Cape of Good Hope; the westerly variation following the easterly, the same as in the northern hemisphere, but in a contrary direction.

And from the observations that have since been made, it appears that the curve of no variation in the northern hemisphere, after passing the meridian of London and Paris, has discontinued its easterly progress; while the curve of no variation in the southern hemisphere, still continues its course north-westward.

The variation on the east side of the curve of no variation, which passed the point of Cape Aguilhas in 1600, and extended north and south to a high degree of latitude in both hemispheres, being westerly; and the curve which passed the meridian of London in 1662 being easterly; it follows, that the curve which passed London could not reach beyond the 18th degree of east longitude, as the denomination of the variation was the same eastward of that meridian in 1600 that it now is, namely, westerly. The exact point where the southerm curve of no variation passed the northern curve cannot be satisfactorily ascertained; but it is known, that while the northern curve passed London eastward, the southern curve passed westward in nearly the same longitude.

Dampier, in his voyage to the East Indies in 1669, found, that from 6° south latitude and 25° west longitude, to the point where the 37th degree of south latitude was intersected by the meridian of Greenwich, the variation was easterly, but never exceeding 10°; at which latter point the easterly variation was 0°; and thence became westerly, and continued to increase to 45° E. long., and 25° S. lat., where it appears to have attained its maximum; i.e. 25° or 26° W.; and from this point the variation gradually diminished, till it again assumed another denomination in S. lat. 10°, and E. long. 125°; and from this last point, as far north of the equator as 10°, the variation appears to have then been, as it still is, influenced by local attractions; the quantity being always small, sometimes easterly, and at other west.

Captain Cook, in 1772, in S. lat. 6°, and W. long. 106°, found 30° 30' westerly variation; and in S. lat. 24°, and W. long. 23° 51', found only 39' westerly variation. From this point the westerly variation gradually increased, as the southern latitude and easterly longitude augmented to 60° of easter longitude, and 60° of south latitude, where it attained its maximum; i.e. 45° 45' easter.

From this last point it rapidly decreased, and became easter in S. lat. 58° 35', and E. long. 142° 45'. But as the tract of D'Entrecasteaux, in 1791, nearly coincides with Dampier's in 1669, the change in the position of the curve of no variation, will be best illustrated by a comparison of their respective observations.

D'Entrecasteaux found the variation in S. lat. 6°, and W. long. 25°, to be 7° 15' easter; and in S. lat. 25°, and W. long. 25°, only 1° 50' easter; from which last point it again increased as the west longitude diminished, till the meridian of Greenwich intercepted the 33d degree of south latitude, where the variation was 15° easter; and it attained its maximum of 30° 48° 9' in S. lat. 34° 52', and E. long. 30° 14° 18' from Paris; and from hence, to S. lat. 44°, and W. long. 133°, the variation continued westerly, but it there changed and became easter.

The space between the two curves observed by Dampier in 1669, reached from the meridian of Greenwich to 130° E. long.; and the distance between them, according to D'Entrecasteaux, in 1791, must be 155°. Dampier having cut the curve in 80° E. long., and the other in 25° W. The curve of no variation must therefore have advanced from the westward annually about 16', in the parallel of 34° south latitude, to have shifted its place 25° in ninety-two years, and at a yearly rate of 14° 8', from the time it passed Cape Aguilhas in 1660 to 1791. This curve is now known to extend across the magnetic and terrestrial equators, to a point in N. lat. 37° 27', and W. long. 70° 44'.

From a comparison of the above results, and others drawn from the observations of captain Flinders, and the Russian navigator Krufenstern, it appears, that a curve of no variation bending westward, extends from the highest degree of southern latitude, in about 144° E. long., to 52° N. lat. in the same parallel, interfering the equator in 150° E. long.
